Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Action of albuminous bodies on blood clotting, 193
Action of borax and boracic acid, 715
Acute hydramnios, Dr. Holmes, 241
Acute inflammation of the bladder, Dr. Vintras, 109
Acute rheumatism, Dr. Macalister, 595
Address in medicine, the, 141
Adelaide hospital, the new buildings, 701
Adenoids and nocturnal incontinence, 446
Adiposis dolorosa, 202
Administration of anæsthetics, 721
Admiralty concession to naval medical officers, 340
Adrenalin, 641
Advance of surgery during thirty years, Mr. M. Robson, 371
Age in reference to cancer, 227
Albuminoid assimilation in the stomach, 164
Albuminuria and exercise, 337
Albuminuria of pregnancy, 329
Alcohol and research work, 693
Alcohol as a medicine, 576
Alcoholisation of women, 557
Algeoscope, the, 164
Allbutt, Dr., dilatation of the stomach, 135
Alleged ill-treatment of an asylum patient, 68
Allen, Dr. R. S., testimonial to, 508
Allinson, Mr., as an anti-vaccinator, 589
Alpine accidents, 202
Amateur anæsthetist, the, 500
American medical etiquette, 95
American medical mendicant, a, 479
Americanisation of our drinking habits, 96
Anæmias, Dr. D. Walsh, 323
Anæmia recurrens, 111
Aneurysm due to tuberculous lesions, 559
Anno Domini 1902, 717
Annual medical service at St. Paul's, 389
Anthrax in Bradford, 462
Anti-alcohol maniac, an, 527
Anti-mosquito campaign, the, 333
Antiphlogistine, 256
Antiseptic properties of perfumes, 226
Anti-staphylococcic serum, 242
Anti-tetanus serum, 385
Anti-tuberculous (bovine) immunisation, 223
Anti-typhoid inoculation, 276
An unrepentant "Vanity Fair," 581
Antistreptococcus serum in scarlatina, 608
Anti-vaccinationist tactics, 453
Apollinaris company, action against the, 589
Apothecaries' hall, Ireland, 180
Apothecaries society of London (pass list), 49, 99, 207, 369, 397, 479, 589, 701
Appendicitis, 163, 521, 569
Appendicitis in mummies, 583
Appendicitis, when to operate in, 379
Appendicular actinomysos, 722
Appointments—end of each No.
Arsenic in health and disease, 17
Arsenic in medicine, 44
Arsenic or no arsenic? 701
Arsenical poisoning, 500
Arsenicated tobacco, 414
Arterio-sclerosis, 634
Articular rheumatism, 556
Ascending paralysis, Dr. Parsons, 105.
Ascites and surgery, 415.
Aspirin, 550
Assault on a medical man, 645.
Asthenopia, Dr. Campbell (illustrated), 158.
Asylum reports, 60.
Asylums for the insane, Dr. Vintras, 265.
Atmospheric electricity, 172.
Atrophic paralysis of the left arm, 715
Audition olore, 467.
Automatic fever indicator, 554 .
Ayres, Mr. L., case of, 614.

Bacillus coli in ice-cream, Professor Klein, 514.
Bacon-Shakespeare controversy, 277.
Bacteriæmia, 640.
Bactericide action of soap, 466.
Bacteriological diagnosis of typhoid, 249.
Bacteriology of puerperal fever, 19.
Bad language in the streets, 366
Bakehouse legislation, 14.
Banti's disease, 111, 329, 357
Barber's shop as a small-pox centre, 528.
Bardswell, Dr., dietetic treatment of pulmonary tuberculosis, 266; dilatation of the stomach, 354.
Barie, Dr., heart in acute articular rheumatism, 703
Barlow, Sir T., natural history of disease, 129.
Barmaids and legislation, 64.
Barr, Dr., tuberculous peritonitis, 679
Basedow's disease, 36
Baths for the people, 91.
Bearding the barber, 444.
Beck and call of general practice, the, 663
Beer yeast, 659.
Beer yeast and pulmonary affections, 110.
Belfast workhouse, 503.
Bennett, Dr., unreduced subclavicular dislocation of the head of the humerus, 566.
Bequests of brains, 583.
Beri-beri, 271.
Berlin conference on tuberculosis, 495, 554
Bewley, Dr., and Mr. Scott, case of lymphadenoma associated with recurrent fever, 708
Bibliography of appendicitis, 41.
Bifid scrotum, 250
Bigham, Mr. Justice, and the N.S.P.C.C., 611
Birmingham university students agitate, 508.
Births—end of each No.
Bishop, Mr., uniting divided intestine (illustrated), 235; prolapsus uteri, 675.
Bishops and babies, 670.
Blood examinations in cases of abdominal disease, Dr. Longridge, 184.
Blood pressure computation, 12.
Body-snatching in America, 555
Boracic acid in milk, 220; shrimps, 479
Bournemouth medical motorists, 529
Bovis, Dr. de, traumatic scarlatina, 321, 350
Bovine tuberculosis, 526, 687
Boyd, Dr., sugar in the urine, 31
Bubonic plague, 531
Bramwell, Dr. B., syphilis and life insurance, 621
Branchial cyst, Mr. Berry (illustrated), 489
Brand's fever food—meat-juice, 126
Brides-Salins, 37, 62.
British association for the advancement of science, 341.
British medical association at Manchester (illustrated), 121, 149, 165, 191.
Bromipine, 608.
Building acts and fire protection, 418.
Bullet extractions and nitrous oxide, 643.
Bullet lying in cardiac wall, 661.
Burglar posing as medical man, 173.
Burnet, Dr., pure ethyl chloride as a general anæsthetic, 624.
Burns, 250.
Buzzard, Dr., functional and organic paralysis, 237.
Byno-cascaeada, 507

Cadaveric fatty pneumonary embolism, 687
Cadbury's milk chocolate, 507
Caldwell, Major, aspects of modern sewage dsposal, 326.
Campbell, Dr. J., presentation to, 71.
Campbell, Mr. K., the normal fundus (illustrated), 27.
Canada, 173.
Canaries and Madeira in winter, 635, 661
Cancer in India, 198.
Cancer in Scotland, 642.
Cancer literature, 522.
Cancer of the appendix, 70.
Cancer research, 141, 181; fund, 479.
Cannabis indica, 249.
Carbolic acid to be scheduled, 619.
Carbon monoxide asphyxia, 445.
Carbon monoxide poisoning, Messrs. Redmond and McWalter, 261
Carbonic acid and digestion, 439.
Carbonic acid in tuberculosis, 416.
Carcinoma a cause of appendicitis, 201
Carcinoma and diabetes, 660.
Carcinoma in women, Dr. Sinclair, 132.
Carcinoma of the vermiform appendix, 336.
Cardiac affections, 110.
Cardiac asthenia, 328.
Cardiac paralysis under chloroform, 45.
Carpenter, Dr., malignant-endocarditis, 233.
Catholic university school of medicine, 673.
Cautley, Dr., etiology of tuberculous peritonitis, 705
Cavendish lectures, Sir F. Treves, 1.
Cemetery scandal, a, 226.
Census of Dublin, 126.
Central midwives' board, 586, 619.
Cerebral abscess, 410.
Cervical paralysis, 244.
Chair of natural history in Queen's College, Belfast, 420.
Changes in the surgical staff at King's college hospital, 502
Chapman, Mr., dietetic treatment of pulmonary tuberculosis, 264; dilatation of the stomach, 354
Charing-cross hospital, 99; medical school, 396.
Chauvinism in medicine, 724
Children's society, annual dinner of, 148.
Chinese medicine, 93.
Chinese surgery, 137.
Chloroform, deaths under, 49, 283, 345, 368, 424, 479, 509, 535, 561, 589, 619, 645, 701, 729
Chloride of calcium, 575.
Chlorosis and sudden death, 215.
Cholera and plague in Egypt, 114.
Cholera in Egypt, 257, 283.
Cholera in Palestine, 508
Choledochotony for chronic jaundice, Mr. A. Doran, 569.
"Christian" names, 643.
Christmas fare, on, 669.
Chronic nephritis, 194.
Chronic progressive deafness, Mr. Collier, 209.
Cider, 68.
Cinematographist, a would-be royal, 69.
Cirrhosis of the liver, 439
Cities of the future, 66.
Civilisation and the birth-rate, 221.
Clarke, Dr., flat-foot, 511.
Clerical longevity, 474.
Clergyman's sore throat, 471.
Cocaine, death from, 561.
Cocainisation of the spinal cord, 576
Coccygodynia, Mr. Smith, 347.
Cockles and typhoid fever, 694

Cocaine habit, the, 42.
Coleridge on cancer research, 335.
Collier, Mr. M., chronic progresssive deafness, 209.
Colour vision of Egyptian natives, 116.
Commonwealth of science, 579.
Cœliotomy, Mr. Jessett, 429.
Concerning asafœtida, 94.
Concretio pericardii, 577.
Concussion of the brain, 36.
Conflict of medical testimony, Dr. Ormsby, 537, 580.
Conjoint board of Scotland (pass list), 153, 509.
Conjoint examination in Ireland, 99, 127, 181, 397, 453, 509, 561.
Consumption, 409.
Consumption among the insane, 361.
Consumption in Belfast, 367, 391.
Consumption in Cheshire, 75.
Consumption in Ireland, 442.
Consumption scare, 387.
Contagiousness of pneumonia, 447.
Continental crusade against alcohol and corsets, 244.
Continental health-resorts, 37, 63, 89, 218, 244, 331.
Contract practice at Swansea, 673.
Contract practice in Cambridgeshire, 362.
Contract practice struggle, the, 529.
Contravention of the lunacy acts, penalty for, 397.
Control of consumption by the public health authority, Dr. Kirkpatrick, 647.
Cooling of houses, 501.
Cork medical and surgical society, 535.
Coronation gift, the, 199.
Coronation honours, the, 22; for Ireland, 16; for Scotland, 16.
Coronation stands and hospitals, 43.
Coroners and fees to hospital medical officers, 696
Coroners and unqualified practitioners, 365.
Coroners' courts and hospital consultants, 723

Prompt cure of eczema, sycosis impeligo and allied dermatoses by formalin, 23
Quackery, the prevention of, 476
Rainsbury, Dr., the case of, 229, 368, 698
Retro-peritoneal fatty tumour, 72
Scientific aspect of the Bacon-Shakespeare controversy, 341, 392
Sudden death and nux vomica, 393
Sunstroke and dietary, 153, 177
Surgical sick rack (illustrated), 282
Turpentine as a deodorant, 254
Whooping-cough, 533
Whooping-cough in public conveyances, 283

Cosmetic injections of paraffin, 615.
Cosmopolitanism in medicine, 468
Cost of the small-pox epidemic, 98.
Council election of the R.C.S. Eng., 45.
Counter-prescribing, 385.
Coxameter, a new (illustrated), 451.
Credeism in the new-born, 330.
Cretinism, 381.
Criminal anthropometry, 333.
Criminal degeneracy, 113.
Criminal statistics, Ireland, 355.
Crises in diseases, 174
Crush of the thorax, 193.
Cumulative action of digitalis, 358
"Cure de montagne," 219
"Cure" of consumption, 414.
Curious censure of an asylum staff, 199.
Curious charge against a medical man, 386.
Curious gift to a hospital, 673.
Cytology of the blood in malignant diseases, 362.

Dangerous disinfectant, a, 43.
Dangers of picric acid, 585
Deafness and hearing exercises, 687
Death of a football player from tetanus, 257.
Deaths under anæsthetics, 692
Death under ether, 619.
Deaths—end of each No.
Decaying woodwork, 172.
Deceptive impressions, 609.
Deciduoma malignum, Dr. Snow, 6.
"Decollement traumatique," 523.
Delayed rickets, 268.
Delenda est anopheles, 174
Delimitation of the heart, Dr. Potain, 77.
Delivery by Bossi's method, Dr. Macnaughton-Jones, 9.
De-nicotined tobacco, 200.
Dental antiseptics, 498.
Dental hospital of London, 98.
Dental surgery, London school of, 127.
Dental sepsis and systemic disease, Mr. H. Sewill, 431
Depopulation of Ireland, 471.
Dercum's disease, 447
Dermoid of the bladder, 466
Destructor refuse, 669.
Determination of animal and human blood, 493.
Diagnosis and prognosis, 246.
Diagnosis puncture, 117.
Diaries and almanacks, 727
Dietetic treatment of pulmonary tuberculosis, Dr. Bardswell and Mr. Chapman, 264.
Diet in advanced life, 67.
Difficult diagnosis, 231.
Diffuse adhesive peritonitis, 87.
Dilatation of the stomach, Dr. Allbutt, 135.
Dilatation of the stomach, 356.
Dilatation of the stomach, Dr. Bardswell and Mr. Chapman, 354.
Diphtheria, 11.
Diphtheria in Carlisle, 669.
Diseases of old age, 242.
Diseases of the stomach and life insurance, 500.
Disinfection for yellow fever, 498.
Dispensing fatalities, 701
Disposal of the dead, 640.
Disregistered man a medical practitioner? is, 70.
Divergent opinions on appendicitis, 714
Docking the salary of a medical officer, 561.
Double pyosalphinx, Dr. Hodgson, 156.
Double tongue, a, 146.
Drawback of lady doctors, a, 225.
Drawbacks of soothing mixtures, 385.
Drinking cups, the dangers of, 641.
Drouet institute, the, 668.
Dublin death-rate, 181, 207, 231, 257, 283, 345, 479, 561, 589, 619, 673.
Dublin sanitary association, 49.
Dublin university biological society, 589.
Dublin university, conferring degrees, 48.
Dublin university (pass list), 25, 49.
Duckworth, Sir D., knowledge and wisdom in medicine, 374.
Dudley, Lady, the illness of, 670.
Duke, Mr. A., heart's action during illness, 9; obstructive dysmenorrhœa, 625
Dunn, Mr. P., an improved model eye (illustrated), 651.
Duplicate stethoscope, the, 386.
Durham university (pass list), 369, 425, 509.
Dutch treatment of epilepsy, 600.
Dysmenorrhœa, 639; the treatment of, 388

Earl Dudley and the medical profession, 690
Early diagnosis of malignant disease of the uterus, 168.
Earrings again, 335.
Eastern erysipelas, 11.
Eccles, Mr., value of the imperfectly descended testis, 237.
Ecclesiastical hygiene, 345.
Ectopic pregnancy in left broad ligament, Mr. O'Callaghan, 569.
Edinburgh tragedy, an, 25

The Cavendish Lecture
ON
INFLAMMATION OF THE VERMIFORM APPENDIX.

⁂ *Abstract of Lecture delivered before the West London Medico-Chirurgical Society, at the Town Hall, Hammersmith, on June 20th, 1902,*

BY SIR FREDERICK TREVES, K.C.V.O., C.B., F.R.C S.ENG.,

SURGEON TO H.M. THE KING; CONSULTING SURGEON TO THE LONDON HOSPITAL.

IF we remember that this is the commonest acute malady met with in the abdomen, excepting possibly the complications of hernia, it is really astounding that twenty years ago this affection was unknown. It was not until the year 1886 that the very name itself had any existence. I need not say that under no circumstances is appendicitis to be regarded as a new disease. The disease is not new, but newly-discovered: it has been hidden for centuries under a lot of vague clinical facts and medical verbiage.

The point that should be first insisted upon in connection with this malady is this: it is a pure peritonitis. It is very desirable, therefore, that in speaking of this affection we speak of a definite form of peritonitis, and the features and complications and possibilities of the malady and the treatment to a certain extent are simply those of peritonitis. Appendicitis is an inflammatory trouble due to certain micro-organisms, and it begins as a catarrh, excepting cases of actual torsion. I do not propose to say anything in detail as to the causes, or reputed causes, of this malady. We know it is most common in young people, 80 per cent. of the cases coming under the age of thirty years, and, curiously enough, 73 per cent. occuring in males.

I should like to draw attention to certain factors in the cause of appendicitis which I think have a good deal to do with the treatment of the disease. The first factor is the extraordinary effect of a tropical or sub-tropical climate. I think therefore that no person should be allowed to go to a tropical country if he is a suspected subject of trouble in the appendix. It is very noteworthy how persons who have had a little suspicion of this malady in themselves will come to an acute termination of it after having gone to reside in a tropical or sub-tropical climate. Another curious point is the frequent coincidence in the female subject of an attack of appendicitis with the menstrual period. It cannot be an accident, because in one particular case that I had the attack occurred on the fourth or fifth day and never varied from that. One might say that out of nine or ten attacks in females perhaps as many as four or five will be associated with the menstrual period.

The last point in this connection is one that I am sure will be at once agreed to by everybody in this room, and it is this. If there is one solitary factor in the production of appendicitis which is overwhelming it is a loaded cæcum. Nothing plays, I think, so important a part in the prophylactic treatment of appendicitis as the recognition of the fact that if the cæcum can be kept free from indigestible food and undigested food the risk of attack is very much minimised.

With regard to clinical matters, I want to deal with the so-called McBurney's point. Tenderness at this magic spot has become a sort of talisman. The hand of the experienced man is put on the spot and there is tenderness and the patient has got appendicitis. It is said to be always present in every case of appendicitis, it is said to be not present in other troubles met with in the abdomen. It is said to indicate the seat of the disease, it is said by some to indicate the position of the diseased appendix. It is said by others who are more cautious—by McBurney to wit—that it actually indicates the precise base of the appendix. The construction that I would venture to put upon it is this. There is a certain tenderness in the right iliac fossa in appendicitis and McBurney's spot corresponds roughly to the centre of the right iliac fossa and therefore it is reasonably the place where tenderness is exhibited. Next, it is a symptom quite common in other maladies, most notably in colitis. In the next place I should say that it is a feature exceedingly common in perfectly healthy individuals in a quite normal state. Last of all, it does not indicate the situation of the disease and it does not indicate, which McBurney insists that it does, the situation of the base of the appendix. Any man operating and cutting through the situation at this point will know perfectly well that there may be tenderness there, and the base of the appendix does not correspond to that spot. Feeling that it was a matter that needed investigation, I asked Dr. A. Keith if he would carry on investigations on certain lines that I indicated, and I am deeply indebted to him for the admirable manner in which these investigations were carried out. What struck me was this. So many persons are tender at certain points in the right iliac fossa, and very often acutely tender. But there is no such point on the left side, and there must be something, therefore, anatomically different there. What is it? The ureter or what? This is how the facts come out. Sections were made along the spino-umbilical line; that line measures in the normal male adult six inches and it crosses the rectus muscle at the anatomical point known as Munro's point, and it roughly corresponds there to McBurney's point. Well, now, the ureter has nothing to do with Munro's point, because it does not cross the line there. Exactly the same condition exists on the left side, so that nothing is to be learnt from that. The next thing is this. The structure that exactly comes beneath that point is the ileo-cæcal valve. The tender thing that can be discovered in the body of a healthy person at that spot is the ileo-cæcal valve. As you know, all orifices are peculiarly well supplied with nerve fibres and are peculiarly sensitive, such as the sphincter of the anus, the orifice of the pylorus, and other sphincter-like openings. That that is the cause of the tenderness in that particular spot admits of no dispute. The base of the appendix, you will be surprised to hear, is one inch below McBurney's point, as discovered in fifty bodies prepared by formalin. Dr. Keith was good enough to examine the bodies of twenty-seven living medical students with this result:—in eleven the point of tenderness was exactly on the point; in nine it was a little above the point; and in four it was a little below the point. Those data pretty nearly correspond *pro rata* with the condition found in fifty hardened bodies by formalin. Moreover, in only three out of twenty-seven students was there any particularly tender spot in the right iliac fossa; in none was there any tenderness discovered on the left side of the body. That, I think, should render definite the circumstances about McBurney's point and the part it plays in this trouble. Any medical man present who has examined in detail cases of colitis will well know the extraordinary tenderness there is often discovered and maintained at McBurney's point.

I want at this stage to say one word about phantom appendix—an appendix described as vertical, of the size of your little finger, and sometimes lying obliquely. That appendix is a phantom and it is a curious phantom. The vertical appendix is due to constriction of the uppermost fibres of the rectus muscle that can be often excited by stimulating the nerve as it enters the muscle. I need not remind you that the appendix, the cæcum, the peritoneum surrounding them, and the muscles of the abdomen which cover them and the skin which covers these muscles, are all supplied by one nerve, in the main the eleventh dorsal. Even when the patient is under anæsthesia a little hard pressure in that spot where the nerve enters the rectus muscle will bring out this vertical appendix.

Now for the operative treatment of this trouble, and first as to the general death-rate from appendicitis. Of course, hospital cases are cases of certain gravity, and in those cases the death-rate is estimated at something like 15 per cent. But take ten medical men who have practised in a large town for, say, twenty years, and therefore must have had to deal with a great many cases of appendicitis. What number have they lost in that period? They would be shocked at the suggestion that they had lost 15 per cent. It is impossible, therefore, to get quite at the figure. But records have been obtained casually from practitioners and also from the German army in time of peace. It is curious that in both these instances the figure comes out at 5 per cent. I know that this figure is open to dispute, but still I do not think that out of 100 cases of appendicitis I have lost more than five in the course of my private practice. I think, therefore, that 5 per cent. may be accepted as the general rate of mortality in appendicitis. When one goes further into the question of operative treatment of appendicitis the whole crux is, What is to be done during an acute attack? There are certain men whose opinions must be listened to who assert that you must operate in every case of appendicitis as soon as the diagnosis is made. I know that that is not perhaps quite the common position taken up by surgeons in this country, but, as you know, it is almost universal—at least, in America. An operation, they say, should be carried out as soon as the diagnosis is made—not on the second, third, fourth, or fifth day. There are others who operate only on compulsion; they say, "No, the majority of the patients get well," and they only operate in exceedingly acute cases in which pus is evident or in cases that are really spun out and going to such a length that they feel there must be some condition within the iliac fossa which can only be reached by operation. Those are the two sides of it.

Speaking from no other than the very uncertain basis of one's own experience, I would take the opportunity of submitting these isolated points to your consideration, believing that they form the basis upon which something like a sound opinion can be arrived at. First of all there are advocates of what may be called indiscriminate operation. They use terms of this sort—"You must operate; the appendix is ruptured; there is perforation; there is acute peritonitis; there is gangrene." And mark—and this is the point that I want to draw attention to—these expressions are used exactly in the same sense as you use such expressions as "There is perforation of the bowel; there is a perforating ulcer in the stomach; there is gangrene or hernia of the intestine." And so they say an operation must be carried out even before a reasonable diagnosis has been made, as soon as an attack is suspected. What I very seriously object to is this: that the two things are put in the same category. It is an absolutely false analogy and distinctly misleading. Is it for one moment reasonable to put perforation of the appendix in the same category with perforation of the stomach? It is monstrous. Not only can a perforation of a fair size occur in the appendix, but a fair degree of gangrene may be met with without causing serious symptoms. I have found a concretion lying outside the appendix one month after an attack, when all the symptoms have subsided and without a single drop of pus. That must have been due to rupture of the appendix or perforation of the appendix or, if you like, gangrene of the appendix. Is it very reasonable, therefore, to use those terms in the same sense as you use the term rupture of the bowel, gangrene of the ileum, or perforation of the stomach? The analogy is absolutely unjustifiable. The second fact that I do not think can be pressed too strongly is this. The very great majority of all cases of appendicitis get well spontaneously. The third fact, which I think should be emphasised as strongly as the last one, is this: operation during an acute attack of appendicitis is attended with great risk to life. What that risk is we again have great difficulty in expressing in figures because they are not easy to get hold of. But we must take things as they are, and I have been at infinite pains to go through records by hundreds and the death-rate in cases of operation—I do not say what operation—during an acute attack comes out at about 20 per cent. Some of the hospital records come out higher than that. The fourth point is a little by the way. Relapses may occur after an operation carried out during an acute attack and that is a thing which must not be quite pooh-poohed. The last thing which I should like to impress upon your memories in very large letters, so to speak, is that the removal of the appendix during the quiescent period is attended with infinitely small risk.

If these facts are accepted, then I think the line of treatment is not difficult to establish and may be pretty clearly defined. Acting upon what one believes to be the best information that the records at present provide in the various directions that I have indicated, I think one comes to some such conclusion as this: All that we know of the pathology of inflammation of the appendix is positively opposite to the teaching that operation should be carried out the moment the diagnosis is made. I think that that cannot be put too strongly. We know a good deal about the pathology of this trouble, and I think that what we do know will not support the dictum that as soon as the diagnosis is made operation should be carried out. The second point is this. An immediate operation should be carried out in all the ultra-acute cases. It is often said that you cannot diagnose them. I would venture to controvert that statement. I believe all these cases are easily recognised, although there are two perfectly distinct types of these ultra-acute cases. There are some in which the local manifestations are not very striking and where the overwhelming symptom is that the patient has introduced into his system a gigantic dose of poison, with a temperature of 104° or 105° F., with the pain not very striking. Those are cases of septicæmia of the most intense character and the patient dies, perhaps, within thirty-six or forty-eight hours. In such cases the operation will probably do no good, but it can do no possible harm, and it should be as a matter of positive routine carried out. The second class of acute cases also cannot be mistaken. It is exactly parallel to perforation of the stomach, and I do not think anyone can have any difficulty in recognising the acute peritonism. The ultra-acute cases cannot be operated upon too soon. The third proposition, which I hope also will meet with your approval, is this: an immediate operation should be carried out as soon as there is any suspicion of pus. I suppose that will be universally accepted. I do not want a demonstration of pus, but a reasonable suspicion of it.

If those three propositions are accepted that takes us a long way. What, then, with regard to the residue of these cases which represents the great mass of cases of appendicitis? I have excluded all the ultra-acute cases and I have excluded those cases in which there is pus, and I think that in the cases that remain it is seldom imperative that an operation should be discussed until about the fifth day. I think that you will agree with me that in a case of appendicitis, if the temperature comes down and is getting towards normal about the fifth day your anxiety is becoming comparatively slight. And because the temperature keeps up after that day the case is not necessarily doomed, though very probably it will have to be dealt with. Having excluded the cases that I have mentioned I think that the phenomena associated with this malady will bear out that somewhat moderate suggestion in the matter of practice that the surgeon should hold his hand until some such time as the fifth day has been reached, when the requirements of the case will have been made quite manifest. Another matter that I will trouble you with is with regard to operative treatment carried out during the quiescent period. It so happened that in a paper which I read before the Royal Medical and Chirurgical Society in 1887 I ventured to suggest that appendicitis when relapsing should be treated by removal of the appendix during the quiescent period. Looking back on the discussion which followed that paper it is curious to note how very feebly it was received, and how the method advocated therein was scarcely accepted at all as a reasonable method of treatment. In that particular discussion one physician of considerable experience said that in the whole of his life he had never seen a case of typhlitis that could possibly have called for surgical interference of any sort. So that the reception of that paper was one which, I must confess, condemned me very much. Still, I do not think one has any reason to complain of the infrequency with which the operation is carried out at the present day. I have since that particular date removed the appendix during the quiescent period over 1,000 times, and out of that number I have lost two patients. I could without being very Jesuitical exclude one of those cases, because it was not primarily a case of appendicitis, but where there was a mass in the right iliac fossa, and where as a result the appendix was concerned. But I will acknowledge the two deaths.

The next point that I want to ask you to consider is this, and it is a difficult matter in practice: When should this operation be carried out? A patient comes to you and says, "I have had one attack," and you might almost tell him that the operation is so trifling that he should have the suspected organ removed. But the whole question is summed up in this: What is the probability of relapse? It is a curious thing that the percentage of relapses has greatly gone up. At one time there were said to be very few relapses—from 20 to 30 per cent. I am quite certain that it is safe to say nowadays that the great majority will relapse. Therefore I think it could be put down, as a line to guide one in directing this matter, that it is desirable to remove the appendix after the first definite attack. The line of argument is this. In the majority of cases there will be a relapse and the patient must feel that the weight of figures is against him. Secondly, the risk of the operation is really almost infinitesimal and will in time become quite trivial. There is just this little sort of comment to be made on a bold assertion of that kind. If there has been an abscess in the first attack then I think an operation may be put out of court altogether because that abscess will in certainly 95 per cent. of the cases obliterate the organ and render it harmless.

Well, then, I have been frequently asked this question: What has been your experience of cases that do not relapse? Going back as I can now over some years, and having seen some thousands of cases of appendicitis, I have seen a great many patients who have had only one attack and having known their career for a number of years, I have come to the conclusion that single attacks may have been due to gross dietetic errors, and may never recur unless those errors are repeated.

With regard to chronic appendicitis I think that in every such case the appendix should be removed when there is no other treatment for it.

Last of all I must say this: The removal of the appendix is not a panacea for every ill in the lower part of the abdomen, because there is apparently an impression abroad in the present day that any kind of disturbance below the umbilicus must of necessity involve the removal of this very much discussed organ.

THE FUNDAMENTAL PRINCIPLES
OF A
RATIONAL DIABETIC DIET.

By Dr. RUDOLF KOLISCH,
Lecturer on Medicine at the University of Vienna.

The treatment of diabetes comprises two principal objects, viz., to maintain the strength of the patient by adequate nutrition and to increase his toleration for carbohydrates.

The importance of providing for adequate nutrition in diabetes is evident in view of the emaciation which is almost invariably associated with the disease. We have, however, to decide whether the emaciation of diabetic patients and the consequent debility are the direct result of digestive disturbances, or are present merely as complications, or whether they are due to an inappropriate dietary. In other words, does a diabetic patient necessarily lose flesh when he is given a sufficient quantity of nourishing food; that is to say, in quantities corresponding to the requirements of the normal healthy individual? The observations of Mering, Vort, Noorden seem to show that this is not the case. Weintrand and Pautz state that a person suffering from diabetes can subsist on a diet not exceeding that of the healthy individual. One of Weinirand's diabetic patients, who was given a diet corresponding to twenty-five calories per kilogramme per day, not only maintained his weight but actually put on 6·5 kilogrammes. This observation appears to justify the conclusion that a diabetic patient in reality requires a smaller number of calories than a healthy person.

I long since arrived at the same conclusion by observation of diabetic patients who had been placed on a vegetable diet. In this I see a case of self-protection of the organism, which adjusts itself to a smaller quantity of food, when the conditions of nourishment are unfavourable; an analogy is to be found in the behaviour of a starving organism. The difficulties and the degree of this adjustment vary with each individual case. Special difficulties present themselves when unfavourable conditions of nutrition supervene suddenly, as in acute cases. On account of irrational dieting, especially in the direction of over-feeding, this endeavour on the part of the organism may be frustrated, whereas, on the contrary, a careful regulation of the quantity of food promotes a salutary reaction. In every diabetic diet I hold it to be most necessary that the nourishing condition for each patient should be tested, and that the minimum quantity should be ascertained on which the patient can exist, and that the organism should become accustomed to this reduction of quantity.

Very little attention has hitherto been directed to this factor in diabetic therapeutics, and the dieting from a quantitative point of view has merely been regulated in accordance with the general principles of the theory of calories; the number of calories required being calculated from the body weight. The slow adaptation of the system to a reduced diet follows exactly the same law, whatever the reason for the reduction of food may be. It is a well recognised fact that the system can be trained to exist on small quantities of food. From this point of view the experience of the Japanese doctors is especially interesting. They teach that with a fixed diet (a vegetable diet) the natives are satisfied with a remarkably small number of heat-producing foods, in spite of which their capacity for work remains undiminished.

I long since called attention to the fact that a diabetic patient, who had been put on a vegetable diet, when the number of calories supplied is far below the average, can exist a long time, and even put on weight. The vegetable regimen provides a diet on which the subject can maintain his usual weight on the minimum number of calories, especially if there be no necessity for him to work. In respect of an invalid's diet the question of course does not enter.

These conclusions do not apply only to diabetic therapeutics, but to all similar conditions, inasmuch as they show that the quality of the food is of great importance in its bearing on metabolic assimilation in each individual case. It is, however, of especial interest in the treatment of diabetes since we require to reduce the quantity of food without causing inanition. The suitability of a smaller diet for diabetic patients was known to Bouchardat, whose maxim for this class of patient was *mangez le moins possible*. This injunction I unhesitatingly endorse. As has already been pointed out, the ideal to be aimed at in the diet is to find out the minimum on which the organism can exist without loss of weight.

This theory is based on the consideration of the absorptive processes taking place in diabetes. Most authors state that in diabetes there is a diminution in the absorption of sugar. The manifest increase of urinary sugar following the absorption of carbohydrates affords the main argument in support of this theory. A large number of facts can, however, be cited, which cannot be explained by this theory. Many diabetic subjects, for example, who are able to digest a small quantity of carbohydrates, if fed on albumen manifest an increase of urinary sugar. The fact that glycosuria is influenced by the ingestion of albumen suggests another theory on diabetic metabolism, viz., that diabetic glycosuria is brought about by an increased formation of sugar from the tissues. We know that carbohydrate and albumen in the body form highly complex compounds, and that under certain circumstances the component parts thereof become separated. If carbohydrates are liberated it is unnecessary for the nitrogenous substances, after the breaking up of the sugar, to be resolved into their constituents, but may be retained in the body in one form or another. From this it will be seen that sugar can be built up in the system from nitrogenous substances without causing any increase of nitrogen in the urine. Therefore the quantity of nitrogen in the urine cannot be taken as an index of the amount of nitrogen-containing substances employed in sugar formation.

Kolisch communicated this theory many years ago, and at a later date it was accepted by Umber and Pavy. The latter regards the carbohydrates existing in the protoplasmic molecule as side-chains which can more easily be attacked than the nucleus of nitrogen. This view of Pavy's helps one to understand the process in question. Pavy expresses the idea by saying that the breaking up of the side-chains has no influence on the separation of nitrogen. Only when all the side-chains are broken up and the nucleus is beginning to be decomposed can a relationship exist between the sugar and the nitrogen in the urine. My personal opinion is that even then by the retention of nitrogen this relationship can be altered to the disadvantage of the nitrogen.

If the separation of the carbohydrate group from the protoplasmic molecule, which unquestionably represents a process existing in the normal organism, is increased through some influence—a poison, for instance—we speak of an increased formation or breaking up of sugar molecules when the quantity of nitrogen in the urine remains unaltered. If this increased formation continues, as in diabetes, it will impoverish the system in respect of carbon.

This separation of sugar will last so long as sugar-forming compounds are present in the body, and will vary in extent according to the intensity of the irritation by which it is produced. In this way an explanation is afforded of a number of facts in the pathology of diabetes which was impossible by the theory of disturbance of sugar formation. It is a fact that in seven cases of diabetes observed shortly before death the glycosuria diminished. If we assume that the glycosuria is produced only as the result of a reduction of the power of breaking up the sugar, this fact is incapable of explanation. It is impossible to accept the theory that at the climax of the disease the power of preventing the formation of sugar has suddenly come into play. It is, on the contrary, quite easy to understand that the store of carbohydrates in the body has been exhausted, and that no further formation of sugar is possible. The fact that in diabetes at this stage, in whom the glycosuria has disappeared, the ingestion of carbohydrate no longer produces any increase in the urinary sugar is now also explained. We can imagine that the carbohydrates taken with the food will be used in the first place to supply the deficiency of carbon. Therefore in coma the possibility of an intravenous diffusion of sugar appears worthy of consideration. In favour of the adoption of the theory of separation of sugar by irritation, the frequent appearance of spontaneous fluctuation of glycosuria may be adduced. We frequently notice that with a practically uniform diet a sudden increase of glycosuria to the extent of one or two per cent., which disappears as suddenly as it came. These oscillations cannot be explained on the theory of the impaired absorption of sugar.

The irritation theory is partly confirmed by the reduction of the diabetic glycosuria which follows the administration of opium. It is not to be supposed that opium causes a strengthening of the function of the cells which has been disturbed by the assimilation of sugar, whereas sedative action of opium on an irritative process can readily be grasped.

Moreover, against the theory of the disturbed assimilation of sugar are certain chemical theories. In E. Fischer's works on the subject it is clearly stated that the assimilation of a substance by the cells depends on the similar configuration existing between the molecules. These statements do not apply merely to enzymes and one-celled organisms such as yeast, but also to the cellular structures of the animal body. The value of carbohydrates in the body is governed by these chemical laws, the greater or smaller usefulness of the various carbohydrates in the system is in direct proportion to the existence of analogous chemical groups in the protoplasm, which, according to Fischer, fit as the key to the lock. Therefore all alterations in the toleration for carbohydrates must be associated with an alteration in the chemical composition of the protoplasm, otherwise the cases in which there is a sudden appearance of glycosuria are incapable of explanation, as, for example, the experimental cases. On the other hand, they are easily understood if we admit the "irritation theory," which assumes the existence of copious sugar formation at the expense of the tissues.

The most powerful argument in favour of the theory of a disturbed assimilation of sugar in diabetes, is the continuance of the diabetic glycosuria on a diet of carbohydrate; in many cases the whole of the sugar ingested appears in the urine. This direct quantitative relationship between the sugar ingested in, and that appearing in the urine is however not the rule.

Trustworthy observations teach us that in cases in which the so-called toleration limit for sugar has been fixed, that not all the sugar which is in excess of this limit is excreted (Kulz, Mering).

Kulz, for instance, gives the following:

Excretion in the urine.

Intake of 30 grms. of dextrose	4 grs.
„ 50 „	5 grs. (not 4 + 20).
„ 90 „	13 grs. (4 + 60).

I can myself give numerous examples in which, apparently, by increasing the intake of carbohydrates, the toleration is increased, as for example, when an intake of 50 grms. of carbohydrates = 10 grs., *i.e.*, a 20 per cent., while with an intake of 100 grms. of carbohydrates still only 10 grms. is excreted, *e.g.*, 10 per cent. In many diabetics the proportion of urinary sugar remains constant in spite of variations in the amount of carbohydrates ingested at any rate, within certain limits.

Naunyn describes the case as "paradoxical glycosuria" When, on the other hand, after a long period of abstention from carbohydrates they are better borne, we must not, as is usually the case, jump to the conclusion that by deprivation of carbohydrates the function of the assimilation of sugar is spared and therefore strengthened. If we remember that the assimilation of sugar is a purely chemical process depending on the existence of certain chemical constituents of the protoplasmic molecule such a theory will be seen to be untenable. These considerations suggest that the behaviour of diabetics may be explained by the fact of suppression of carbohydrates; that is to say, that a diminution of the intake of carbohydrate diminishes the material from which the sugar is derived. I wish to insist on these data as affording a most important therapeutic indication, viz., to allow diabetic patients as much carbohydrate as they can bear, taking into account the glycosuria, otherwise the system soon gets deficient in carbon.

It must be clearly understood that both the quality and quantity of the carbohydrates have an important bearing in determining the maximum amount of carbohydrates that can be taken, as will be clear from the influence of albumen on the glycosuria. That diabetic glycosuria is increased by the ingestion of albumen was long since proved by Bouchardat, Pavy and Cantani. The discovery by Pavy of complex carbohydrate compounds in the molecule of albumen originated the idea that this preformed carbohydrate molecule is the source of the glycosuria after a meal rich in albumen. This theory gained additional plausibility by the researches of Schondorff, who succeeded in showing that only those molecules of albumen form glycogen in the animal body which contain ready-formed carbohydrate molecules. Schondorff fed his patient on casein, an albuminous substance from which, up to the present, no ready-formed carbohydrate has been isolated, and he found no increase in the glycogen. The accuracy of Schondorff's conclusions has not, however, been demonstrated, and they have been called in question by Bendex, Cremer, Cohn, who assert that under suitable conditions the casein can yield the material for the formation of a large amount of sugar.

That it cannot be the ready formed sugar which, in diabetes, leads to an increase of glycosuria on the ingestion of albumen has been demonstrated in the older writings of Kulz, who proved that casein can cause a marked increase in the glycosuria. The latest chemical researches on the nature of the albuminous sugars negative the opinion that the preformed sugar is the source of the increased glycosuria.

The works of Müller, Neuberg, Blumenthal and Mayer, and especially those of Lingstein, show without a shadow of a doubt that the sugar in albumen is identical with chitosamim. According to the researches of Fabian, Offer and Fränkel, chitosamim is not an intermediate form of glycogen, so it cannot be the source of the increased formation of dextrose. The chief argument against the formation of carbohydrate in diabetes from the preformed carbohydrate in albumen molecules lies in their quantitative relationships. According to Kossel, at least 80 per cent. of the carbon in albumen exists in the form of hexonbases and amido acids, so that at the most only 20 per cent. can exist as preformed sugar. As a matter of fact, up to the present, only 1·10 per cent. has been separated.

It follows therefore that the sugar must be synthetically formed from the albumen.

The quantitative relation between albumen and the sugar formed therefrom in the organism has not yet been definitely settled. There seem to be the widest variations from a quantitative point of view between the various albuminous bodies, and also between the normal and diabetic organisms.

Many facts may tend to produce diabetic glycosuria after the ingestion of albumen, as I have already pointed out in my text-book on "Diabetic Therapeutics." Albumen is the nutritive base which is the starting point of organic oxidation processes, as albumen is most nearly related to the protoplasm of the tissues. Albumen, moreover, exerts the greatest stimulation to nutrition. The ingested albumen will be decomposed as supplied without regard to the necessity therefor. The decomposition, however, is preceded by the entrance of the albumen-molecule into the cell protoplasm, or at least an intimate contact between the nutrient albumen and the protoplasm must be brought about. In this way a greater attraction is exerted on the protoplasm. This attraction can split up the protoplasmic molecule, which consists of albumen, carbohydrate, fat, salts, &c., and in this way, with a food consisting of albumen, the formation of sugar by the breaking down of the protoplasm can take place. At the same time the disintegrated albumen is the source of the material from which sugar is synthetically built up, and to such a degree that theoretically, after deduction of the carbon excreted in the urine, 1 gramme of nitrogen is equivalent to 8 grammes of sugar.

From the researches of phlorizin diabetes and pancreatic diabetes much smaller values were found, viz., 1 : 2,8 (Minkowski), 1 : 3,2 (Muller), 1 : 4,2 (Lusk and Halsev).

In the experimental results it is always assumed that the total amount of sugar present in the urine is formed exclusively from the albumen, the index of which represents the amount of nitrogen excreted in the urine.

In this connection it has not been taken into consideration that sugar may also have been separated from the higher forms of proteids, whose nitrogen is being retained within the body. Now and then in some certain cases the above figures are exceeded, and a larger quantity of sugar appears in the urine, more even than the proportion corresponding to 1·8. Some authors admit a sugar formation from fat. (Noorden, Rumpf, Rosenquit, Mohr.)

In this theory we challenge the values ascribed to the nitrogen as being disproportionate to the amount of decomposed albumen, as well as the view that nitrogen is readily retained. The latest researches of Lowi, Lusk, Hirschfeld, militate greatly, on quite other grounds, against the theory of the formation of sugar from fat. Hirschfeld, for example, found that in a phlorizinised animal glycosuria is reduced considerably if the supply of albumen is diminished and the decomposition of fat increased. Lowi has proved the retention of nitrogen in phlorizin glycosuria. The fact, moreover, that excess of sugar secretion beyond the theoretically possible quantity (from albumen) is only met with in the severest cases, shortly before death, renders it possible that in these cases nitrogen is retained in the system. These facts can be explained if the sugar is split off from the albumen as I have suggested. The formation of sugar such as we have already insisted upon, must lead to a deficiency in the amount of carbon in the body, and therefore in extreme cases, when compensation is not possible, it must lead to a dissolution of the organism. It is very remarkable, and the fact is also of great importance in dietetic therapeutics, that the various albuminous bodies behave in different ways on diabetic glycosuria. From this point of view I may recall the fact discovered by me that the vegetable albumen has not nearly as marked an effect in increasing diabetic glycosuria as that produced by animal albumen. The study of the different animal albumens reveals a large number of facts which tend to show that great differences exist between their respective behaviour.

Luthje found an especially well-marked increase in the glycosuria when patients were fed on nutrose (casein) and pancreatic substances, and a less-marked increase in the amount on feeding with albumen and thymus. Sandmeyer observed the increase only on giving raw pancreas, and when this was cooked it was absent. This is explained by the ferment action of the pancreas and better digestion of the food. Halsey, in phlorizin animals, observed a different behaviour to that of Luthje, in that he noticed a greater increase after albumen. Rengi and Reale found it to be more marked with nuclein. The negative behaviour of thymus, as explained by Luthje, is incomprehensible. These contradictory statements make it possible that the different albuminous bodies supply the material for the synthetical formation of sugar, but that they are not all of the same value in their bearing on diabetic glycosuria.

From this point of view the irritative action which has been repeatedly referred to upon the protoplasm plays an important part, since, according to the quality of the albuminous bodies, so the sugar-production varies in intensity.

From what precedes we are therefore justified in concluding (1) that the individual treatment of diabetes has not only to first discover, as has hitherto been done, the so-called toleration capacity for carbohydrates, but the dieting requirements of the organism and the minimum of nutriment on which the patient can exist. If the feasible demand for food should gradually be reduced. (2) The toleration capacity for carbohydrate really depends upon the composition of the food which is given apart from carbohydrates, and therefore such food is to be selected as contains the maximum of carbohydrate that can be tolerated. In this direction it is advisable to limit the quantity of albumen to that absolutely necessary. (3) A vegetable diet agrees with diabetes better than any other, inasmuch as it contains the minimum number of calories, the minimum of albumen, and the maximum of carbohydrates. (4) The proportion of fat must be determined in accordance with general diabetic requirements.

The fourth Scandinavian Medical Congress will be held at Helsingfors from July 4th to 6th.

IS THERE ANY REAL "DECIDUOMA MALIGNUM?" (a)

By HERBERT SNOW, M.D. Lond., &c.,

Senior Acting-Surgeon, Cancer Hospital.

By this query it is not, of course, intended to deny the long-established sequence of malignant developments following immediately upon, and often unmistakably caused by, the trauma of parturition; but to investigate how far these developments show any title to a special term differentiating them from the ordinary cancerous new-growths appearing in or about the uterus, without any question of pregnancy.

Strong doubts on the point have several times been expressed before the Society by myself and others. I therefore thought it desirable to thresh the matter out, if possible, more completely. After putting down this paper, I found that the subject had already been very ably and amply dealt with in a communication to the Obstetrical Society by Dr. T. W. Eden (*Obst. Trans.* vol. 38, 1826); and have accordingly largely availed myself of this elaborate digest—which I would recommend anyone tempted to swell the huge flood of "deciduoma" literature, first to read.

This flood was first let loose upon us by Sänger in 1889 (Ueber sarcoma uteri deciduo-cellulare, *Cent. f. Gynak*). A primipara, æt. 23, fell from a railway carriage, and aborted at the eighth week. She had continuous hæmorrhage for three weeks, and in the fourth high fever. The curette was resorted to, with relief to the bleeding, but otherwise no improvement, on the contrary an extensive inflammatory exudation appeared around the uterus, which itself became larger. There was also a large swelling in the left iliac fossa, thought to be purulent but found to be otherwise. Death took place seven months afterwards, with signs of pulmonary metastasis. The growth proved under the microscope to be a "sarcoma." Sänger thought it had developed in the decidua, simply because it contained numbers of large cells identical with decidual cells; and also "plasmodia" resembling the decidual giant-cells. He did not suggest that fœtal structures played any part in the development. Since then, as Dr. Eden well remarks, "Almost every malignant growth discovered in the puerperium has been called in Germany *deciduoma.*" And now our American cousins have also taken the matter up with considerable zeal.

Now the difficulty in accepting this view of Sänger's lies in the fact that the decidua contains no cell-elements distinguishable from those of ordinary connective tissue, so that even if the decidua, or some remnant of it, did generate a new growth, we should not be able to differentiate this microscopically from ordinary sarcoma or myo-sarcoma. And to constitute the disease a distinct cancer species, it would be requisite to demonstrate special symptoms, or a clinical career materially differing from that of the latter.

Since 1889, however, the question has been considerably expanded, and I fear at the same time obscured by becoming mixed up with that of placental development; and with the controversy whether the terminal epithelial layers of the chorionic villus are both fœtal, or one maternal. I would remind the Society that the outer layer, considered by some to be maternal, is described as "a thin stratum of granular protoplasm, showing no differentiation into cells." At irregular intervals are small oval nuclei. This layer constitutes the —in this connection—highly-celebrated "syncytium," and often spreads out into large "plasmodia."

The inner layer (Langhan's) consists, on the other hand, of distinctly differentiated epithelial cells with large round or oval nuclei. It is contended by some that this layer is not concerned in the generation of D. malignum, though every microscopist must recognise the difficulty of establishing such a position when a malignant growth is in question.

The reference of deciduoma to chorionic epithelium obviously controverts the views of the originator, and implies that the title he bestowed on it is erroneous. But assuming for the moment that the reference is accurate, we have then to ask, whether there is a specific *epithelial* cell element which will enable us to differentiate "deciduoma malignum" when we encounter it? It has been already shown that there is no such badge of connective tissue origin, because the decidua contains no pathognomonic cell whatever.

(a) Read before the British Gynæcological Society, June 12th, 1902.

Everything here turns on the "syncytium," and the "plasmodial masses" supposed to be derived therefrom. No chorionic villi have ever been detected in these growths.

Now the most learned pathologist extant could not give any definite opinion upon the precise nature of a malignant growth, based merely on plates in professional journals, supposed to depict microscopic phenomena. How much less the ordinary gynæcologist, who has to run and read! The difficulty is at the present time enhanced by the prevailing fashion of reproducing micro-photographs, which are always in the highest degree misleading, when any malignant cell-growth is concerned. A conscientious drawing *may* convey the truth, but a micro-photograph *cannot*. The phenomena visible in a microscopic field are so complex that it is utterly impossible to reason about them collectively. You can prove anything only by partially ignoring them, just as the mathematician has to define the line as "length without breadth." No line is without breadth, but for the particular purpose in view, that breadth must perforce be ignored.

Then, again, as I have often previously pointed out, the habit, so far as I know universal among professional pathologists, of examining prepared sections only, involves numerous errors. It must be stigmatised as vicious and pre-eminently unscientific. A prepared thin section admirably displays the motology of a morbid growth, and the correlation or distribution of its component cells. But, as a rule, the process of preparation for section-cutting completely disguises the shape of those cells, to say nothing of (perhaps) other important characters. On a correct appreciation, however, of the shape alone an accurate recognition of the species of a malignant lesion commonly hinges.

No microscopic report in such a connection should be held valid without resort to each of the two methods. It should also contain a description or delineation of the individual cells as nearly as possible in their natural state; in addition to the routine account of their distribution in the prepared thin section.

I would remind the Society that the cases of "D. malignum" have been mostly recorded by gynæcologists, who have met with only this single instance, and with the majority of whom, pathology is hardly a strong point.

But experts in the habit of microscopically examining other forms of malignant tumour, state that there is absolutely nothing in the so-called "plasmodial" cell-masses, which cannot be exactly parallelled by the sections of any rapidly-growing sarcoma from other parts of the body. In the latter you commonly find large masses of nuclei embedded in a jelly-like material which in the prepared thin section exhibits no distinction of separate cells, though indeed, on examining a simple "scraping" with the aid of a gentian violet, or some similar stain, there is no difficulty in discriminating the cell-elements, spindle-shaped and multi nucleated.

The differentiation of D. malignum on microscopic evidence alone, whether an epithelial or a connective tissue origin be in question, thus falls to the ground; and the talk of "plasmodial" masses, referable to the "syncytium," can be characterised only as "jargon."

Before leaving the microscope I exhibit the *Journal of Pathology and Bacteriology* for October, 1898, which contains an instructive example of what I regard as the manufacture of this supposititious lesion solely on microscopic evidence. A case is very elaborately reported by Professor J. K. Keily and Dr. Treacher, who refer its origin to the chorionic epithelium, and illustrate their paper by micro-photographs. If you look at Figs. 8 and 9, Pl. xxxviii, you see the delineation of a "large plasmodium," on the faith of a micro-photographic view assuredly not sufficiently clear to warrant such a construction, and displaying no feature whatever not found in ordinary sarcoma of other parts. Secondly, when you turn to Fig. 14, Plate xxxix., you see what appears to be a mass of huge spindle-shaped nuclei and cells, characteristic of sarcoma, or of what is most probable, when the uterus is concerned, of myo-sarcoma, arising from the muscular nuclei.

As some reference was made here recently to certain "branching cells" as characteristic, I also exhibit the drawing by myself of a typical myxoma, as published in my "Treatise on Cancers," showing similar cells.

We will now glance at some of the typical cases, mainly with the view of discovering whether, as the microscopic evidence fails, there is anything in the clinical history to warrant the view of a distinct cancer species.

At the April meeting of this Society, our esteemed President reported a case. He expressly stated that he did so on the strength of a microscopic report furnished to him. There had been no pregnancy for six years. The only unusual clinical feature was the occurrence of a secondary nodule, I think, on the vulva. His paper I regard as specially valuable in the present connection, because it demonstrates that lesions, which expert microscopists identify with D. malignum, attack the uterus altogether apart from pregnancy.

Marchand (*a*) records two cases. In the first a girl, æt. 17, had a bleeding tumour of the vaginal wall which was scraped. It recurred in a few days, and was scraped again. A large abdominal tumour appeared, followed by death in three weeks from pulmonary embolism. At the autopsy a distended and ruptured left Fallopian tube was found; it contained a necrotic mass resembling placental tissue, and growing apparently from its wall.

No fœtus and no chorionic villi were detected. There was no evidence of pregnancy in any shape; and the case may very well have been a primary malignant tumour of the Fallopian tube.

His second case was that of a noni-parà, æt. 34. There was severe hæmorrhage in the third week after a normal labour at full term. A large quantity of blood-clot and placental-looking tissue were removed. Hæmorrhage recurred four months later; and was similarly treated. On a third attack within a few weeks, the patient was anæsthetised. The uterus was found enlarged, retroverted, and adherent to the floor of Douglas' pouch. In attempting to replace it perforation by the sound occurred, so hysterectomy was performed. The woman remained well six months afterwards.

There is obviously no clinical symptom differentiating this case from one of ordinary uterine carcinoma.

Whitridge Williams's case ("Johns Hopkins Hosp. Reports," vol. iv., No. 9), was that of a negress, VI.-para, æt. 35. In the second week after normal labour a small painful nodule appeared in the right labium majora. By the fifth week this had reached the size of a hen's egg, and began to slough. The woman died three months afterwards, seemingly of septicæmia. An extensive sloughing tumour of the vulva, a small secondary growth in the vaginal wall, two small tumours in the uterus, the larger only 1¼ in. by ⅞ in. by ¾ in., metastases in left ovary, lungs, spleen, and kidneys were the post-mortem phenomena. The existence of any uterine tumour had not been suspected till the autopsy.

There can be little question that the vulvar growth was here the primary lesion.

Gottschalk's case ("Das Sarcoma der Chorionzotten," *Archiv f. Gynak.*, Bd. XLVI.) was that of a V.-para, æt. 42. Severe hæmorrhage occurred about the sixth week of the puerperium. Curette used, and again twice in the next four months. The enlarged uterus was then explored, and soft masses twice removed by the fingers. A prompt recurrence led to hysterectomy in August, 1892, six months after the first attack of hæmorrhage, which is assumed to have been due to a miscarriage. The woman remained well till the January following. Then a large mass appeared in the right hypochondrium, and death followed in March. There were metastases in the lungs, spleen, and right kidney.

Gottschalk believes that his case arose from the

(*a*) *Centralblatt f. Gynak.*, 1889, viii., 132.

sarcomatous transformation of the stroma of retained chorionic villi. Eden states that the structures figured as sarcomatous villi, are very little like villi at all, and doubts the fact of gestation. The clinical history is obviously in no wise distinctive.

Miss Julia Cock's case (*Brit. Med. Jour.*, 1895, p. 1,819) was that of a woman, æt. 30, who had been three weeks confined of her fourth child. The labour was normal, and the placenta considered complete. Severe hæmorrhage took place on June 19th. On the 20th, under anæsthesia, a mass, in appearance and touch resembling placental tissue, was found adherent to the posterior uterine wall, and was removed by the finger and curette. The patient died on July 25th, seven weeks after labour. Metastases were found in an ovary and in both lungs.

I will ask you particularly to note this case; because it exemplifies the most important practical corollary I shall presently lay before you, Unfortunately as usual, the early history is defective. But even in the most acute forms of cancer some time is required for the development of widely sundered metastases; and there can be no doubt that the malignancy had been commenced long before parturition, to say the least.

Kelly and Treacher's case cited above (*Journal of Pathology and Bacteriology*, 1898, No. iii., vol. V.) refers to a II.-para, æt. 29. On February 2nd she consulted her medical attendant for hæmoptysis, supposed to be tuberculous. On June 18th she passed a mole as large as a Jaffa orange. On August 7th a growth was found on the anterior vaginal wall and was diagnosed as an "ulcerating hæmatoma." The patient died on October 19th. At the autopsy the posterior uterine wall was found occupied by a tumour as large as an orange, resembling, to the naked eye, placental tissue. Huge masses occurred on both sides of the vagina and cervix. The vessels were very large and numerous; one large vein was filled by an oval mass of new growth. Both lungs were full of secondary metastases.

The history denotes malignancy of many months' standing at the lowest computation. We may not unreasonably infer therefrom that it preceded the pregnancy and caused the eventual death of the fœtus. Hæmoptysis, presumably due to the pulmonary metastases, is described as the first ill-symptom. That would imply an advanced stage of disease. We are not told when impregnation actually took place.

Dr. Herbert Spencer's case (*Obst. Trans.*, 1896, xxxviii.) was that of a II.-para, æt. 27. Hæmorrhage occurred twenty-eight days after labour. Death followed ten and a-half weeks after delivery. An ulcerated and gangrenous growth was found at the placental site; the ulceration having nearly perforated the fundus. There were metastases in the cervix and lungs. Apparently a "large-celled sarcoma with typical syncytium."

Here again was a malignant lesion of long-standing. There does not appear in the report anything to show decidual origin.

Immediately preceding this in the volume (*Obstet. Transac.*, xxxviii.) is another headed "Deciduoma Malignum," and recorded by Mr. Rutherford Morison. A woman, IX.-para, æt. 35, bled seriously six weeks after confinement. This was followed by other attacks. The Clinical Research Association reported the scrapings to show "abundant evidence of squamous-celled epithelioma." There was subsequent recurrence in the lungs and death.

Apfelstadt and Aschoff (*Archiv f. Gynak.*, vol 1, 1896) record two cases. A woman, æt. 33, aborted at the fourth month, on October 4th, 1894. The membranes were passed unruptured. Severe uterine hæmorrhages followed. On February 5th, 1895, a mass was removed from the uterus. On May 17th the curette was used. On May 24th hysterectomy was performed, with death on the twenty-sixth day subsequently. The uterus contained a cancerous growth. There were metastases in liver, both lungs, pancreas, mesentery, intestines, and cancellous tissue of head of one femur.

The second patient was æt. 42, and was delivered of a vesicular mole on March 21st, 1895. The left labium became swollen, and the swelling extended up the vagina. On June 19th it was laid open; then, to the surprise of the observers, tissue "broadly resembling a vesicular mole was found growing from its walls." On June 20th similar masses were removed from the uterine cavity. The woman died from pyæmia on July 25th. The spleen and lungs were secondarily implicated.

The extensive secondary lesions of the first case make it noteworthy. They denote a lapse of many months, and the almost certain commencement of the malignant process before impregnation. The second would seem to have been a primary sarcoma of the labium or vagina, acute under the hyperæmia of pregnancy.

Lastly, I would merely cite a case reported by Schauta (*Centralb. f. Gynak*, vol. IX., 1895), because, in connection with it we find formulated (*Brit. Med. Journ. Abstract*, April 13th, 1895) the highest ultra-refinement upon this hypothetical decidual or chorionic lesion by division into three distinct forms.

"In the first, proliferation of the connective tissue of a decidual relic occurs (Gottschalk's sarcoma of the chorionic villi). In the second, the epithelium of the villi proliferates (Klein's carcinoma of the villi). In the third and commonest variety, the decidua cells and not the epithelium of the villi proliferate; hence the new growth must be reckoned as a sarcoma (sarcoma deciduo-cellulare, according to Schauta)."

Truly a pathological net, with meshes sufficiently wide!

S. Eden's verdict on the twenty-eight cases recorded to 1896 is that "several were ordinary forms of uterine cancer. The remainder all possess the general characters of sarcomata."

I submit that the only conclusions possible under the circumstances are that the term "D. malignum" is misleading and should be abolished. That, so far, no valid evidence of the generation of malignant growths from placental structures, whether decidual or chorionic, has yet been adduced. That the lesions described under the above title do not differ, microscopically or clinically, from the ordinary malignant diseases of the uterus, carcinoma, sarcoma or myo-sarcoma.

Moreover, I would strongly urge on the Society that the practical bearing of the cases so reported has, in eagerness to startle us with something rare and strange, been overlooked, for the records of a considerable number indicate that the malignancy had commenced before impregnation, but had not been recognised until, in most instances, abortion—in a very few, delivery at full term—had taken place. The latter event is, of course, rare, and not to be accepted without scrutiny. Still I cannot see how the clinical facts can be interpreted otherwise. We find ourselves face to face with extensive lesions which must have been established long before parturition. What we know of cancer causation elsewhere renders it highly improbable that they can have commenced during pregnancy. You never have "cancer" set up, while healthy cell proliferation is going on. The only inference possible is, that the malignant development must have begun before impregnation; the phenomena of cancer in the uterine body, always for a time obscure and insidious, being masked by the pregnancy.

Unfortunately, all the histories I have read are extremely defective, both as to the mode of causation, and the early career. Many bear eloquent testimony to the futility, and indeed to the dangers, of the curette, in these puerperal cases; often used, as it were, in the dark. The only valid treatment is complete hysterectomy.

With greater circumspection and more accurate diagnosis in the early months of pregnancy; with recognition of a possible concealed malignant lesion concurrent with a living fœtus; with the precaution to dilate and examine digitally, before resorting to the curette during the puerperium, some of the disasters here apparent should be rendered impossible in the future.

Civil Surgeon McLibin has succumbed to typhoid fever on the journey back from the Cape. His body was brought ashore at Southampton last week from the transport *Plassy*.

A NOTE ON THE
IMPORTANCE OF ATTENTION TO THE HEART'S ACTION DURING ILLNESS.

By ALEXANDER DUKE, F.R.C.P.

The paramount importance of attending to the heart's action during illness of any severity cannot be too strongly enforced on the practitioner. The very common expression, death from "heart failure," has now become so well known that in cases of doubt any layman who reads his daily paper could supply this stereotyped diagnosis.

I have several times seen patients suffering from marked symptoms of functional disorder of kidneys, lungs, liver, &c., where the heart has been entirely overlooked and no examination made of that all-important organ. I have also seen a steam kettle pouring out volumes of moist air which the patient was breathing in under the delusion the bronchial tubes were *altogether* at fault when the real cause (cardiac), was left untreated. On removal of bronchitis kettle and a suitable treatment directed to the heart, the copious expectoration and cough vanished.

"Heart failure," like "influenza," is a most convenient, and, I regret to say, readily accepted diagnosis by the public in general.

What watchmaker (may I ask ?) would think of attending to all the various works of a watch which failed to keep time, without any notice being taken of the mainspring ?

I maintain that in *all cases of serious illness the heart should be first examined*, and also, if necessary, during the course of the illness, so as to assist its action when required, and keep the clock ticking at any cost !

The supreme importance of this common-sense proceeding was forcibly impressed upon my mind some time since when paying a friendly visit to a relative of my own who had been confined to bed for some time, I happened to feel his pulse, and finding it, to say the least, thready, I suggested calling the attention of his medical attendant to the heart, with the result that on treatment being directed to that organ the other symptoms soon vanished, and the patient was restored to health.

No matter how successful the treatment may be in removing abnormal symptoms from other organs of the body. What avails it all if the heart ceases to beat ?

London.

Clinical Records.

DELIVERY BY BOSSI'S METHOD IN A CASE OF ALBUMINURIA AT THE SEVENTH MONTH IN A FIBROMATOUS UTERUS. (*a*)

By H. Macnaughton-Jones, M.D., &c.

Some time since I exhibited before the Society Professor Bossi's instrument for rapid dilatation of the uterus, and specified the cases in which its use was indicated. I have quite recently employed it myself, and desire to say a word as to its action.

The fœtus and placenta shown were removed from a patient who, early in the seventh month, was attacked with somewhat severe hæmorrhage. Her medical adviser, Dr. William Barter, had for some time been aware that she was suffering from albuminuria. This had greatly increased, until the urine became almost solid on boiling. There were, however, no attendant uræmic symptoms, nor any cerebral nor visual disturbances. The hæmorrhage recurring, with some attacks of partial syncope and associated sickness, I was consulted, and advised rapid dilatation and delivery of the child. For a few days there had been an absence of fœtal pulsations and projections. Operation was determined upon.

The patient having been anæsthetised, she was carefully prepared, shaved, and the vagina disinfected. The body of the uterus was found to be fibromatous. In twenty minutes dilatation, without any lesion of the cervix or rupture of the membranes, was effected to the extent of six and a-half centimetres. The presentation was that of an arm, with the head lying in the left iliac fossa. As it was found impossible to move the presentation, the membranes were ruptured. In the attempt to bring the head into position the arm came down, with a loop of the funis. In consequence of the impossibility of introducing the hand into the uterus the greatest difficulty was experienced in effecting version. However, by pushing back the arm and raising the head, the foot was ultimately secured and version effected. Great difficulty was also experienced with the after coming head, which was finally delivered by using the blade of a forceps as a vectis. The placenta was shortly afterwards delivered. The fœtus was discoloured, and decomposition had set in, with attendant desquamation. There had evidently been placentitis, with exudations in parts and degeneration, causing in one portion a rather large separation, with resulting extravasation. Fearing that there might be portions of placental tissue remaining, the uterus was several times explored with an ovum forceps, and some placental *débris* were removed. The uterus was then douched out with formalin solution. Two slight lacerations caused by the delivery of the head were secured with cumol gut, and the vagina was loosely tamponned with iodoform gauze. The whole time occupied from the commencement to the close of the operation was exactly one hour. The patient has done well. The description of the appliance (which can be obtained from Messrs. Arnold and Son) appeared in the *British Gynæcological Journal* of February, 1902, and in the *Lancet* of March 1st, 1902.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.
Meeting held Thursday, June 12th, 1902.

Dr. Heywood Smith, a Vice-President, in the Chair.

The Chairman said that the President, Dr. J. Halliday Croom, who was unfortunately unable to be present, had sent two specimens for the inspection and consideration of the Fellows; the notes on these, read for the President, by Dr. J. J. Macan, were as follows :—

(1) Uterus removed by vaginal hysterectomy for disease supposed to be malignant, but proving to be a fungating fibroid.

(2) Uterus with placenta and large fibroid, removed after Cæsarean section.

The specimen is a uterus removed by vaginal hysterectomy from a woman, æt. 68. There is nothing to record about the operation itself nor about the patient's recovery, which was complete ; but what I have to point out is that this patient was sent to me diagnosed by several medical men as suffering from intra-uterine cancer. She had profuse hæmorrhage, so much so that she was absolutely blanched ; she had a fœtid leucorrhœa and was rapidly losing flesh. A small portion of the uterine tissue removed and examined for me by a microscopist was pronounced malignant, and I therefore decided to operate. About the propriety of performing the operation I have nothing to say, as I believe that it was the best thing to be done for her, but what I want specially to point out is that now, when the uterus has been removed and examination made, the disease proves to be, not cancerous, but simply a fungating fibroid recrudescing in old age. This patient no doubt will live for years, and I shall get the credit of curing cancer, which never existed. This is the second occasion within a short time that this experience has occurred to me, and it is just possible that similar cases may account for many of

---

(*a*) Exhibited before the British Gynæcological Society, June 12th, 1902.

the reported instances of successful vaginal hysterectomy for cancer. Of course, I do not for a moment mean to imply that anybody would willingly record untrue cases, but one might very easily fall into such an error. The other specimen I exhibit is that of a large fibroid associated with a uterus containing a placenta. The patient came to me from Calcutta with this pregnancy and associated fibroid tumour. Of course, a delivery at any time *per vias naturales* was an impossibility. I, therefore, waited until the child was viable, and then performed Cæsarean section in the usual way, and so delivered a child, which lived for some considerable time. I thereafter performed a modification of Porro's operation and removed the uterus and tumour entire. The patient had a very short convalescence and left the home well.

The **CHAIRMAN** said that it hardly appeared from the notes, or from the specimen itself, that, large as the tumour was in the second specimen, delivery was absolutely impossible, but evidently it was best that such a tumour should be removed.

Dr. **ROUTH** pointed out that in regard to the first specimen several medical men and a microscopist, presumably an expert, had declared the disease to be cancer. In this the case resembled many that had come under his own notice, in which disease pronounced to be cancerous had turned out not to be malignant at all; it was much to be deplored that as yet no absolutely certain means of diagnosis had been attained, and the statistics as to alleged cures were, therefore, invalidated. No doubt it was quite possible in many cases for a woman to be delivered *per vias naturales*, in spite of the presence of a large uterine fibroid; he had met with such cases, and in one the tumour was quite as large as that before them, and he was preparing to perform Cæsarean section, but owing to an alteration in the position of the child it was born in the natural way.

Dr. **HODGSON** thought that the removal of the uterus must have been absolutely necessary after the Cæsarean section, as efficient contraction and arrest of hæmorrhage could not be expected considering the size of the tumour.

Dr. J. J. **MACAN** said that, as the Chairman had pointed out, the tumour did appear to be in the upper part of the uterus, and supposing the pelvis to have been of normal size delivery might theoretically have been possible, but even so the tumour would have remained. He thought that they must all agree that, being convinced that delivery could not take place by the natural way, the wisest course was to remove the uterus and the tumour with it.

Dr. **MACNAUGHTON-JONES** read notes of the delivery by Bossi's method, at the seventh month, of a macerated fœtus from a fibromatous uterus in a case of albuminuria, which will be found under the heading of "Clinical Records" at page 9.

Dr. **MACNAUGHTON-JONES** added that he believed this was the first time the instrument had been used in this country. It had been fully described in the *Lancet* as well as in the *Journal* of the Society, without, however, sufficiently pointing out that the sheaths on the end of each blade could be removed and replaced after the os was partially dilated. Without these sheaths there was no difficulty in the initial introduction of the instrument even into an unduly contracted os. Professor Leopold, at Dresden, had used the instrument with singular success in eclampsia, as would be seen from an abstract in the May number of the Society's *Journal* to which Dr. Macan had just drawn his attention; but he had seen Leopold use it also in contracted pelvis.

Dr. F. A. **PURCELL**, instancing a case in which a senile and very friable uterus after the rupture of the pedicle of an expelled fibroid, and during the process of dilatation for the purpose of removing the remains of the pedicle, had been perforated by one of Hegar's dilators, said he thought there would have been no danger of such an accident with Bossi's instrument, and he thought that that instrument might be more widely employed than it had yet been.

Dr. **BARTER**, in reply to the Chair, said he could entirely corroborate all that Dr. Macnaughton-Jones had said as to the satisfactory effect of the instrument in rapidly dilating the cervix without interfering with the membranes in the case before them.

Dr. **HEYWOOD SMITH** exhibited Kurz's suture forceps, and described the ingenious way in which, when one blade had been used as a holder to introduce the threaded needle, on closing the instrument the other blade seized, and, when the blades were again separated, withdrew it.

Dr. **HERBERT SNOW** read a paper entitled "Is There any Real Deciduoma Malignum?" which will be found on page 6.

Dr. **HEYWOOD SMITH** (Chairman), after alluding to the able paper recently read to the Society by their President, Dr. J. Halliday Croom, said that on the question as to whether any line of demarcation at all could be drawn between the so-called deciduoma malignum and ordinary sarcoma of the uterus pathologists held very different views; some light might be thrown upon it by those Fellows of the Society who were working on cancer, if they could decide the actual site of the malignant development that had been called deciduoma malignum. Ordinary sarcoma of the body of the uterus originated in the connective tissue of the uterine wall, and, theoretically, at all events, there would be ground for a distinction between it and deciduoma malignum, if there was any truth in attributing the beginnings of the latter to the decidua. It was a striking fact that in many of the reported cases of this affection the patients seemed to have lost ground rapidly, and to have died soon after curetting. He was himself inclined to think that curetting was too much the fashion, and that it was a proceeding that caused very often more irritation than was intended or desirable, and thereby led to the extension of inflammatory disease or malignant new growth. Much stress had been laid upon the occurrence of secondary deposits in the lungs in deciduoma malignum, but it had not been demonstrated that such metastases manifested themselves more freely in that connection than in ordinary cancer of the body of the uterus. In esteeming a drawing more trustworthy than the reproduction of a microphotograph he thought Dr. Snow was rather hard upon authors who used microphotographs. A drawing was necessarily subject to bias, and its author could not always avoid accentuating, quite involuntarily, some points which a photograph would have represented with more truth.

Dr. **MACNAUGHTON-JONES** maintained that as a certain condition arising out of a pre-existing state of pregnancy had been shown in a very large number of cases to be associated with a definite train of symptoms, they were right in recognising that condition as a distinct disease. With further investigation and more accurate knowledge of its pathogenesis they might agree on a better name for that condition than deciduoma malignum, but he thought that as practical men they must admit its occurrence; whether it approached carcinoma or sarcoma in its histology was of little importance compared with the fact that it was a malignant new growth associated with products of pregnancy, and demanded early recognition and prompt extirpation.

Dr. J. J. **MACAN** said that on one point they must all agree with Dr. Snow, that is to say that the term "deciduoma malignum" was improper and should be abandoned. Writing in 1898, Professor Veit recognised the existence of the disease described by Sänger as "deciduoma malignum," though he considered it to be only a sarcoma modified by pregnancy, and enumerated at least ten names which had been given to it. Dr. Haultain, who in 1899 was able to refer to ninety recorded cases, preferred the name "chorio-epithelioma malignum," suggested and employed by Marchand, or "trophoblastoma" (Kanthack). To the ten enumerated by Veit we might add "epithelioma serotina choriale," "chorio carcinoma," "carcinoma uteri syncytiale," "carcinoma choriogenes uteri," given by various observers, and though the multiplicity of these names indicated opposing views as to pathogenesis, they all recognised the existence of the malignant lesion originally called "deciduoma." Widely as Veit differed from Marchand in his explanation of the facts, there was no variance between them as to the clinical aspects and essential microscopic characteristics of the disease which was met with always in connection with pregnancy, and at the site of the placenta, which caused definite clinical symptoms, hæmorrhage of a profuse spouting character, a foul fœtid discharge, rapid cachexia, fever, and, in default of extirpation, death. It was moreover accompained by a remarkably quick development of secondary deposits, not only in the lungs, as was usually the case, but frequently also in the brain, the liver, and the kidneys, and, as had been recorded time and again, early metastases in the vagina and labia. With that clinical picture of the disease, they had a microscopical aspect so definite that Veit stated that the differences in the conditions reported were unimportant. In no other disease had the characteristic trabecular masses of protoplasm been identified, and in regard to the possibility of the development of sarcoma during pregnancy, Dr. Snow himself stated that as cancer is not set up while healthy cell proliferation is going on, such development was most improbable, nor does the implantation of an ovum in a sarcomatous mucosa seem much less so. Whether it was to be considered a sarcoma, a carcinoma or an epithelioma, this malignant condition had been recognised as constituting a definite disease in such a very large number of cases, by men of well-established reputation in the profession, that it seemed to him idle to ask "Is there any real deciduoma malignum?" By whatever name it might be called, there was such a disease, and they must be prepared to meet and deal with it.

Replying to a question of Dr. **Hodson** in regard to the case recorded by the President being unconnected with pregnancy, Dr. **Macan** pointed out that the President had not excluded the possibility of abortion.

Dr. **Snow**, in reply, said that all who had employed the microscope to any considerable extent would appreciate his remarks about micro-photographs; he objected to them not because they blurred the outline, but because they gave a number of details that were inherently misleading. Nothing was more singular than the absence of English names in connection with deciduoma malignum. There were first of all German cases, then American, and then a few, but for years together not a single one, reported in England, and he thought they could not accept cases merely on the basis of high-sounding names, generally from abroad. There was no definite microscopical aspect whatever in this disease; nothing to distinguish it from sarcoma in other parts of the body; nor clinically anything different from the syndromata of ordinary malignant disease of the uterus, under the added stress of pregnancy. There was in fact nothing to indicate that the so-called deciduoma malignum was a special form of malignant disease which could be attributed to the placental structures.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, June 29th, 1902.

TREATMENT OF DIPHTHERIA.

For the last two or three years Prof. Riegler has treated almost exclusively cases of diphtheria with spray of oxygen water. The results were very encouraging, and seemed to have been quite as good as those obtained by the serum treatment. The false membranes under the oxygen treatment were detached less rapidly, perhaps, than when injections of serum were practised; but, on the other hand, the depressing action of the diphtheritic toxine was in a certain measure paralysed by the peroxide of hydrogen which favoured oxidation.

Our *confrère* recommends gargles night and day with a 3 per cent. solution of oxygen water (two or three tablespoonfuls to a glass of water). In the case of young children who cannot use the gargle he gives the following mixture:—Peroxide of hydrogen, ʒj; syrup, ʒiv; water, ℥iij. A teaspoonful every one or two hours. At the same time the throat is touched with a 3 per cent. solution two or three times a day. These applications are not painful, but should not be repeated too often, as they might provoke in the end œdema of the palate septum.

These gargles of oxygen water have been found equally useful in other non-specific inflammatory affections of the throat and in cases of mercurial stomatitis.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, June 28th, 1902.

GLOSSAL CARCINOMA.

At the "Gesellschaft der Aertze," Gersuny showed a man on whom he had operated three times for carcinoma of the tongue. In April, last year, the cancer was all removed as well as the infiltrative and submaxillary glands. In September a recrudescence commenced, involving the whole tongue as well as the mucous membrane on the floor of the mouth, which again was removed. Again it recurred involving the lower maxilla, which was again removed along with hyoid bone. After this operation the cosmetic effect was improved by the use of paraffin injections, with which the patient soon became fit to take fluid and soft foods easily, while at the same time he was able to talk quite distinctly. This was accomplished by fitting an indiarubber tongue and a denture into the lower maxillary bone, which greatly improved his appearance as well as supplying the defect.

LUPUS TREATMENT.

Ehrman next showed a patient who had suffered from lupus on both cheeks as well as the lips and nose since 1892, which he had treated with resorcin paste (33 per cent.). This soon caused the whole surface to heal except two small points that have remained quite stationary since 1896.

EASTERN ERYSIPELAS.

Spiegler exhibited a curious case of transitory erysipelas peculiar to the East which left behind it peculiar brown pigmented patches, as well as white tufts of hair on the head and eyebrows. The cause of the phenomenon, he thought, was due to a chemical change in the pigment of the hair probably caused by the irritation of the erysipelas.

Ehrmann thought it an anomalous case of pigmentation from syphilis or a sort of leucoderma where the virus had destroyed or caused the pigmentary cell to shrink destroying its functional activity.

Spiegler said that it was not yet clearly decided whether white hair was entirely pigmentless or whether the pigmentary cells produced a white pigment.

Spiegel said the presence of white pigment was a possible theory, but we had not as yet any proof in support of the hypothesis. All pigmenting granules were divided into two parts, viz., pigmentary crystals and colourless granules, so that by a colouration with concentrated methylene blue the pigmentary granules take on a pretty green, which is due to the blue colouring of the ground substance combining with the brown of the pigment giving the resultant green. Moreover, it was possible that the pigmentary granules might lose their brown colour and then leave nothing but a colourless base.

Models of Ear.

Alexander demonstrated two models of the middle and internal ear, fifteen times their natural size. He had also two others, one at birth, the other in old age. It was observed in these latter that the semicircular canals and the cochlea were well developed, while the vestibule was imperfect. None of the adults gave the same thickness of nerve substance, height of cochlea and size of ampulla. The aquæductus cochlea was smaller in the adult than in the infant. Other models of the labyrinth were exhibited to demonstrate the changes throughout life.

Blood Pressure Computation.

Federn stated that he had now been ten years engaged in measuring the blood pressure of patients and of persons in health, as well as animals, and had formulated the following conclusions:—(*a*) The blood pressure is the expression of the gross kinetic force of the heart which is modified by the resistance met with in the vascular system; (*b*) this is characteristically demonstrated by the influence that menstruation has on the pressure curve; (*c*) irritation of the central end of the divided splanchnic nerve raises the blood pressure; (*d*) the lowest limit of normal blood pressure in a healthy man is between fifty and sixty millimetres of mercury =1·868 to 2·361 inches; (*e*) any sensible irritation or stimulus raises the blood pressure forty millimetres = 1·574 inches, which may be reasonably accepted in explanation of the variable results obtained by the different experimenters in this department of physiology; (*f*) the blood pressure is not constant all over the body, but varies in pressure in different regions, even in the corresponding artery on different sides, such as the radial, where a difference of thirty to forty millimetres = 1·186 to 1·574 inches in one side from the other.

The Operating Theatres.

ROYAL FREE HOSPITAL.

Cataract Operation.—Purulent Meningitis.—Mr. H. Work Dodd operated on a man, æt. 88, who had been sent up from the country, being the subject of double senile cataract. The patient was in excellent condition considering his age, being able to get about and taking great interest in everything around him. His organs were healthy, his mental condition was a little senile, his disposition being somewhat amiably childish, with a tendency to excitability. The ordinary three millimetre operation was performed on the right eye under cocaine; it was noticed at the operation that the conjunctival sac was perfectly healthy and the puncta normal. Every precaution in aseptic surgery was taken. The incision being completed the iris was drawn out by the iridectomy forceps, and the ordinary iridectomy performed; at this moment the patient strained badly, being very excited, compressing the eye and thus causing a certain quantity of vitreous to escape. The lens was satisfactorily removed by means of the vectis; the eye was then dressed in the ordinary way and both eyes bandaged and the patient removed to bed. He remained fairly comfortable all day, but during the first night after the operation he suddenly became violently maniacal, struggled forcibly and tore off the dressings from his eyes; it took five or six people to control him and ultimately it was found necessary to put him into a straight jacket; injections of morphia were then given. During the next day he was in a drowsy state, saying he had no pain but did not feel well; on the second day there was no pain in the eye and he was quieter; the lid of the operated eye was red and swollen; in the evening he was very noisy and troublesome and morphia was again injected; the next day the whole of the right eye region was swollen, red and œdematous, there was chemosis, the cornea looked opaque and yellowish, there was pus in the anterior chamber and in the wound; the tongue was very dry and furred, he complained of no pain, and his temperature was normal, as it had been since the operation. The wound being open no treatment in the way of an incision was adopted, and the patient was treated by lotions, &c. During the next few days the eye discharged freely, became cleaner, and the patient himself gradually got more and more sensible. Eighteen days after the operation the man was so well that he was allowed to get up, and from this time forward he had no bad general symptom; the eye itself became gradually cleaner, ultimately healed, and began shrinking. Nine weeks after the first operation the right eye being perfectly clean and free from pus, Mr. Dodd operated on the left eye to remove the cataract by the same method, only the patient was so troublesome during the beginning of the operation that it was deemed advisable to administer chloroform. Unfortunately, in endeavouring to remove the lens with the vectis, the lens could not be got out, but fell back into the vitreous. Dressings and bandages were put on and the patient removed to bed. Forewarned by what happened on the night after the first operation, Mr. Dodd gave orders that morphia should be injected, and the patient remained quite quiet and sensible, sleeping well. The day after the operation he had a rigor; the operated eye, however, looked quite comfortable. After this he continued having almost daily rigors, for which no cause could be found, as the eye itself was entirely free from suppuration. It was noticed, however, that the skin was becoming more and more jaundiced. At Mr. Dodd's request he was seen by Dr. Carr, who found a patch of dulness about the middle of the right lung behind, and advised that this area should be explored for fluid; this was done on the next day under chloroform, but no fluid was found. The opportunity was taken to remove the shrunken right eyeball. The patient recovered very well from the operation, but he continued to have occasional rigors, became semi-conscious, and had to be fed with a tube. From this period he got rapidly worse, and died twenty-two days after the second operation for cataract. At the post-mortem, thirty-six hours after death, rigor mortis was present, body well nourished, skin very yellow, no pus in right orbit from which the eye had been removed by operation. Dura mater very adherent to skull and to brain. Purulent meningitis present, most marked over frontal lobes and base of brain, and extending down spinal cord. Both ventricles filled with thick greenish yellow pus, left ventricle being more distended than right; no pus in either cavernous sinus nor in the lateral sinuses. Small abscesses between middle and lower lobes of right lung. The liver was tough on section, and there was a superficial abscess on upper surface of right lobe, and the hepatic ducts leading to it were full of pus. Impacted in left hepatic duct was a gall-stone about the size of a walnut; there were also some smaller stones in the ducts leading from it; no pus here. The gall-bladder contained bile and no stone. The other organs were fairly normal. Mr. Dodd thought with regard to the whole case that the probability was that septic material had entered at the period when the patient, in his maniacal excitement, had torn off his bandages after the first operation and exposed the wound in the right eye to infection. A mild species of delirium, he pointed out, is not uncommon in old people after cataract operations if both eyes are bandaged up, and it was sometimes well, he considered, if this condition should begin to show itself to give the patient the use of the sound eye, but in this case this could not be done, as the other eye was also affected with cataract, and therefore useless. It was very difficult, he thought, to account for this extraordinary and unfortunate attack of violent mania, as the post-mortem showed the man to be healthy in all his organs excepting that he had gall-stones in his liver; it was a moot question as to whether there was any connection between the gall-stones and the insanity. If the abscess in the liver had existed before the first operation it might account for a great deal both with regard to the mania and to the suppuration. An interesting point was that the second eye which was operated upon did not suppurate, but a most peculiar thing was that the rigors began the day after this second eye had been operated on. This possibly, however, was a mere coincidence. It was, he considered, an unfortunate case all through, though everything, both at the operations and during the subsequent treatment, was done with the greatest care.

Society of Apothecaries of London.

During the June Examinations the following candidates passed in Surgery.—E. W. C. Bradfield (Section I.), H. B. Drake (Section I), G. W. C. Hollist (Sections I. and II.), G. J. Humphreys (Sections I. and II), E. Osborne (Section II.), F. H. Rotherham (Sections I. and II.), E. M. Stacy (Sections I. and II.), C. J. Taylor (Sections I. and II.), W. P. Taylor, J. Vaillant (Sections I. and II), and F. W. B. Young (Sections I. and II.).

Medicine.—W. Ball (Section I.), T. G. Longstaff (Section I.), A. Mooney (Section I.), C. C. Morgan (Section I.), E. C. Pratt, and E. M. Stacy (Sections I. and II.)

Forensic Medicine.—W. Ball, J. C. S. Dunn, T. G. Longstaff, S. J. Meredith, A. Mooney, E. C. Pratt, and E. M. Stacy.

Midwifery.—L. Courtauld, H. E. Darlington, H. B Drake, E. Gray, B. Hirsch, T. G. Longstaff, E. M. Stacy, H. S. Tumber, and P. L. Vawdrey.

The L S.A. Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery and Midwifery.—H. E. Darlington, E. Osborne, E. C. Pratt, F. H. Rotherham, E. M. Stacy, C. J. Taylor and W. P. Taylor.

Death of a Medical Man from Chloroform.

Dr. T. P. Harvey, of Hastings, was found dead in bed a few days since, a partially emptied bottle of chloroform standing on the table beside the bed. He had been much worried of late, and it is surmised that he had taken an overdose of the drug when employing it as a narcotic. A verdict of death by misadventure was returned at the inquest.

Registered for Transmission Abroad.
The Medical Press and Circular.
Publ'shed every Wednesday morning, Price 5d. Pcst free, 5½d.

ADVERTISEMENTS.
For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.
Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.
Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.
Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 2, 1902.

THE KING'S ILLNESS AND THE NATION.

Just as we were going to press last week a great shadow fell upon the nation. On the very eve of the coronation of one of the most popular sovereigns who has ever mounted the throne an implacable illness renders him a helpless and unwilling cause of a really colossal disappointment. The postponement, followed by the announcement that the King was undergoing a grave abdominal operation, constitutes an exceedingly dramatic historical incident. Of the chances of recovery we are most hopeful, even confident, as in the hands of modern surgeons there is an excellent prospect of recovery from perityphlitic abscess if operation be undertaken at a reasonably early period. At the same time there are various points in connection with the King's illness which merit a certain amount of outspoken criticism from the point of view of a medical journal. So far as the diagnosis is concerned the perityphlitis was undoubtedly the cause of the pain in the back which prevented his Majesty from attending the Review at Aldershot about a fortnight ago. We were told that the malady was lumbago from a "chill" and that opium had been administered. As all medical men know, pain in the back is a common sign of inflammation of the colon, so that the King was doubtless suffering from perityphlitis at Aldershot. In spite of that fact he was permitted to drive to Windsor. At the same time a high official of the household reassured an anxious nation by a reply to a London newspaper asking for the truth regarding certain grave rumours: "My best answer is that the King is returning to Windsor." Now, if it were then known that his Majesty was affected with perityphlitis, such an answer is simply trifling with the nation. The *suggestio falsi* is held to be disgraceful in private life, and should be considered no less contemptible in public matters.

If the illness were still considered trifling on the return of the King to Windsor, then we should venture to suggest a remodelling of the medical department of the Household, so that consultations of medical and surgical men actively connected with hospitals might be immediately available upon all occasions. It would be interesting to know at what precise point the diagnosis of perityphlitis was arrived at. While at Windsor the King did not attend Ascot Races, so that he must have been very ill at that time. During those few days the nation was assured that his Majesty had taken carriage exercise freely. It is now generally believed that he did nothing of the kind, and if so, the origin of such absolutely misleading information from official sources demands sifting to the bottom. However that may have been, we hold that from the first the nation was entitled to a clear official announcement as to the precise facts of the illness. Since the operation that course has been adopted, and bulletins have been issued signed by medical men whose names are sufficient guarantee of absolute accuracy. Why should this not always be a matter of routine where Royalty is concerned? In the case of the late President McKinley the earlier reports after the operation were misleading, and filled not only the United States but also the whole world with false hopes. Long ago, in turbulent states of society, there were undoubtedly often grave State reasons for withholding information concerning Royal illnesses. That day is past, however, and with the modern Press it is impossible to conceal the truth for any length of time. It is to be hoped, in the best interests both of Royalty and of the community, any news of the kind may reach the nation from sources that are above suspicion as to their absolute soundness and integrity. Were it not for our implicit trust in the names of the medical men who sign the bulletins posted daily at Buckingham Palace, the report of the present progress of the King would be open to some amount of suspicion. However, we are happy to believe that the diplomatic dallyings with the truth that seem inseparable from the air of Courts and Cabinets are in this instance replaced by the sober statements of fact made by responsible medical men.

BAKEHOUSE LEGISLATION.

THE progress of the sanitary reformer is sure and steady, though often it is extremely slow. No better instance of this tardiness could be found than the way in which bakehouses are being brought within the effective control of the local sanitary authorities. For nearly forty years the subject has been before the public, and the horrors of the cellar bakehouse have been recounted in a fashion not likely to be soon forgotten. The first attempt on the part of the Legislature to control the bakeries was in the year 1863, when the Bakehouse Regulation Act was passed, and some sort of supervision was conferred upon the sanitary authorities as regards leanliness. In 1879 the control was handed over to the factory inspectors, who were already so few in number as to be unable to discharge their existing duties. Under their care the bakehouses fell into a deplorable condition, which continued until, in 1883, control was restored to the vestries. This step in the right direction was strengthened in 1891 by a new Factory Act that gave the inspectors the right of entry at any time, and by the Public Health (London) Act, so far as the Metropolis was concerned, which increased the power to enforce sanitary measures. Then the legislative battle against the underground bakehouse, the source of a great deal of the mischief, began in 1895. In that year a new Factory and Workshop Act enacted that "A place underground shall not be used as a bakehouse unless it was so used at the commencement of this Act." that is to say, on January 1st, 1896. A little practical experience in the working of the Act, however, showed that the clause in question could be readily evaded in the law courts, and much the same observation applies to a similar provision condemning underground bakehouses unless they existed at the time of the passing of the later Factory Act on August 17th, 1901. As the majority of town bakeries are underground, it will be seen that their existence would not be threatened by that provision. The Act of 1901, however, went much further than any previous measure in its determination to put an end to the underground bakehouse. It enacted that "after January 1st, 1904, no underground bakehouse may be used unless the district council is satisfied that it is suitable as regards construction, light, ventilation, and in all other respects." It is apparent that an efficient weapon is thus placed in the hands of the local authorities, but it by no means follows that efficient action will follow. Local bodies are notoriously averse to interference with tradesmen in their district. Moreover, it would be impossible to turn out of their premises at a moment's notice the greater number of the bakers of a given district. Clearly the changes must be anticipated by the action of the borough councils, who will fix standards, and give the bakers due warning of the coming changes. That view is strongly supported by Dr. Orme Dudfield, who has for many years worked faithfully in the cause of bakehouse reform. The subject is one of vital importance to the community. The key to the Public Health aspects of the case was given by Drs. Waldo and Walsh a few years ago when they demonstrated that the interior of a loaf was not necessarily sterilised by baking. The inference clearly is that the pathogenic germs of an infected bakehouse may be distributed to consumers in an active form. This special investigation is well worthy of being conducted much further than was done by the original observers. It is interesting to note that the Medical Officer of Health of Johannesburg, Dr. C. Porter, in an attempt to set in order the bakehouses of that town, directed that all water from suspicious sources should be boiled before being used for making dough. The subject is of first importance to our countrymen in India, where the major part of the bread consumed is made by the natives under filthy conditions. Indeed, there is no civilised country in the world where the subject of bakehouse sanitation is not vital to the welfare of the community.

THE CAVENDISH LECTURE ON APPENDICITIS.

Sir Frederick Treves, in his recent Cavendish lecture on some phases of inflammation of the appendix, of which we publish a full abstract in another column, has ably dealt with a subject which it may safely be said is now attracting world-wide attention. The tragic illness of his Majesty the King on the eve of his coronation has focussed the eyes of all people on the vagaries of the vermiform appendix. Less than twenty years ago appendicitis was practically unrecognised, it found no accepted place in works on medicine, and indeed its very name had not been proposed. It is remarkable that the ages should have gone round and it should have been left for the researchers in the latter years of the nineteenth century to unearth and bring into light the true pathology of this disease. As the lecturer says, "the writing which did more than any other to force upon the medical world a recognition of the true pathology of pericæcal peritonitis was the monograph of Fitz, published in 1886," but this has been ably followed up by his own researches, and assisted by the publications of Deaver, Hawkins, Kelynack, Lockwood, McBurney, Mynter and many other English and American pathologists. The clinical phenomena which are familiarly known as "an attack of appendicitis" are mainly due to the involvement of the peritoneum in the region of the appendix. The disease is essentially a variety of peritonitis. Its manifestations, its effects and its possibilities are those of peritonitis. Sir Frederick Treves, however, contends that appendicitis may occur without symptoms. Extensive inflammation of the appendix leading to great thickening of its walls, to widespread ulceration of its mucous membrane and to some degree even of stenosis, may exist without producing symptoms of any kind. An attack of acute appendicitis may also be preceded by occasions on which the patient has minor seizures of pain in the cæcal district which are of short duration and irregular appearance. In other cases the patient has an abiding trouble in the right iliac fossa which may continue for months, and may or may not be associated with acknowledged attacks of appendicitis. We quite agree that very little is to be gained by the elaborate divisions and sub-divisions which are affected by many in dealing with this matter. The practical conclusion was clearly put by Kelynack in his work on "The Pathology of the Vermiform Appendix," in 1893, when he wrote "whatever pathological grouping of appendicitis may be adopted, the all important practical classification clearly defined in the mind of every physician and surgeon must ever be (1) operative appendicitis and (2) non-operative appendicitis. Such a clearly-defined division is of paramount importance to the patient, for his life will probably depend upon it." Life in a tropical or sub-tropical country is said to have a very marked effect in encouraging appendicitis among Europeans. In female patients an outbreak of appendicitis is frequently coincident with the menstrual period. But the most common and the most conspicuous factor in the ætiology of an attack of appendicitis would seem to be a loaded cæcum. In the treatment of appendicitis, Sir Frederick Treves is a strong opponent of indiscriminate operation. He holds that the greater proportion of cases of appendicitis recover spontaneously, and it is probable that the general mortality of the disease, if examples of all grades be included, is not above 5 per cent. Operations carried out during an acute attack are attended with a risk to life which is considerable, and which is probably expressed by a mortality of over 20 per cent. Relapses may occur after operation carried out during the acute stage. The removal of the appendix during the quiescent period is attended with a very trivial risk, which may be expressed by a mortality of 1 in 500. Immediate operation is demanded at the earliest possible moment in all ultra-acute cases. Immediate operation is also demanded in every case where there is a reasonable suspicion that suppuration has taken place. In other cases the question of operation may be well kept in abeyance during the first few days of the attack, and may usually be left open for decision until the fifth day or after.

Notes on Current Topics.

The English Coronation Honours.

Among the honours conferred upon members of the medical profession, the list whereof is published elsewhere, there are several which will excite special satisfaction in the minds, not only of their recipients, but of their fellow-members of the profession. That Lord Lister, full of years and honours, has been made a member of the Privy Council is a further recognition of the immense benefits which he has conferred upon suffering humanity, benefits in which his Majesty himself now shares. That Sir Frederick Treves should have been made a baronet is in accordance with the fitness of things, having regard to the high position which he has held for years in the surgical world. Should success crown his latest surgical achievement that fact alone will constitute for him a title to the nation's gratitude very inadequately recognised in the honour now bestowed. The Knighthood conferred upon Mr. Victor Horsley is a welcome recognition of a very active and successful career. Young in years, Mr., now Sir, Victor Horsley has made his mark on the scientific surgery of his time, although his indefatigable energy has found employment in many other spheres of professional usefulness. The other knights are all men of whom it may safely be said that one is surprised to find that the distinction had not previously been conferred upon them.

Coronation Honours for Ireland.

Among the names on the list of those on whom the Lord-Lieutenant has, with the approval of his Majesty, announced his intention of conferring the honour of knighthood, are those of two distinguished members of the medical profession—Mr. Thomas Myles, F.R.C.S.I., and Professor William Whitla, M.D. Mr. Thomas Myles has had a distinguished career in his profession. He is the son of a well-known citizen of Limerick, with which city he has still many ties, and was appointed Vice-President of the Royal College of Surgeons in the year 1898, and President in 1900, which office he has but quite recently vacated. He is a visiting surgeon to the Richmond Hospital, and was at one time Professor of Pathology in the School of the Royal College of Surgeons. He has contributed many articles on surgical subjects to the columns of the medical press, and is well known as an operator of high rank. Sir Thomas Myles has in the past taken a deep interest in the welfare of the members of the Army Medical Service and of the Irish Poor-law Service, and has helped in the production of important reforms in these services. We congratulate him on the honour which has been conferred upon him. Professor Whitla is a leading member of the medical profession in Belfast, and is widely known in Ireland and throughout the medical world generally on account of his contributions to medical literature. He is Professor of Materia Medica and Therapeutics in the Queen's College, Belfast, and holds many other important posts. He is the author of a well-known "Manual of Pharmacy, Materia Medica, and Therapeutics," a work which reached its seventh edition in 1898. He has also written an equally well-known "Dictionary of Treatment"; and has made many other contributions to medical literature. Of late, Sir William Whitla's name has been prominently before the members of his profession in Belfast on account of his liberality in presenting the Ulster Medical Society with an institute which will serve as the headquarters of the Society as well as a medical club. His professional brethren will heartily endorse the honour which has been conferred upon him. It cannot, however, be said that honours have been bestowed with a free hand upon the medical profession, and although we do not wish to comment on any omissions, it will occur to many that there are members of the profession who are worthy of a higher honour than that of Knighthood; at least two names occur to us of distinguished medical men who would not have been found unworthy recipients of the higher honour.

Coronation Honours for Scotland.

His Majesty the King has been pleased to create three medical Knights on the occasion of his Coronation. The recipients of the honour are the two Presidents of the Royal Colleges of Edinburgh, and Professor MacEwen, Glasgow University. Professor Thomas Richard Fraser, M.D., LL.D. Glasgow and Aberdeen, F.R.S., President of the Royal College of Physicians, was born in Calcutta in 1841, and, after being educated at Edinburgh University, had the degree of M.D. conferred upon him in 1862. His thesis for that degree was on "The Action and Uses of the Calabar Bean," and gained one of the gold medals given for theses of unusual excellence. His further investigations on this subject were published in the "Transactions" of the Royal Society of Edinburgh, and gained for him the Barbier prize of the French Academy of Science in 1868. This distinguished him as an investigator of the first rank, and determined the further course of his studies—on the properties and actions of drugs. In conjunction with Professor Crum Brown he has done much to demonstrate the relationship between the action of drugs and their chemical composition, and although further research along the lines they opened up has not proved so fruitful as was once anticipated, their work on the action of methyl on such alkaloids as strychnine will always remain classical. Within a year of graduation Dr. Fraser was appointed assistant to Sir Robert Christison, Professor of Materia Medica in the University, and remained in this capacity until 1870, when he became a lecturer on materia medica in the Edinburgh Extra-mural School, and an assistant physician to the Royal Infirmary. About this time he acted as examiner in materia medica and public health in the Edinburgh University, and in materia medica in the London University. On the death of Sir Robert Christison he succeeded to the Chair of Materia Medica in Edinburgh in 1877, and during twenty years of his professorship he acted as Dean of the Medical Faculty. As recipient of the Barbier prize he became a Laureate of the Institute of France. The Lords of the Admiralty chose him as one of the medical members of the committee to inquire into the outbreak of scurvy in Sir George Nares' Arctic Expedition, while his more recent appointment as President of the Plague Commission will be within the recollection of all. Besides those mentioned his contributions to practical medicine have been numerous, and he is perhaps best known as the introducer of strophanthus into the Materia Medica. For his work on this subject he received the Keith Prize of the Royal Society of Edinburgh. Ophthalmologists owe to him eserine, whose myotic qualities he discovered in his researches upon physostigmine. In later years his work on cobra poison, with the discovery of an antitoxin to which he has given the name antivenin, has brought him further credit. His eminence as an investigator, however, is almost rivalled by his skill as a teacher, and to few men who have learned materia medica from "the Dean" will the subject ever again appear dry and uninteresting. He is a deservedly popular Professor, and the honour which he has now received will be received with acclamation. Dr. Halliday Croom, President of the Royal College of Surgeons, is one of the best-known gynæcologists in Great Britain. He was born at Sanquhar, a small village in Dumfriesshire, in 1847, and, like so many other Scotsmen who have risen to fame, is "a son of the manse," his father having been a United Presbyterian clergyman. He graduated M.B. in 1868, and gained a gold medal for his M.D. Thesis in 1882. He began his professional career in Edinburgh in 1870 as assistant to the late Professor Laycock, and subsequently acted for some years as assistant to the present occupant of the Chair of Midwifery in the University of Edinburgh. Thereafter he began to lecture on Midwifery in the Edinburgh Medical School, and has continued doing so up to the present time. He has been a physician to the Maternity Hospital for twenty years, and only about a year ago did his term of office as physician for diseases of women to the Royal Infirmary expire. He has been President of the Edinburgh Obstetrical Society, and is now President of the British Gynæcological Society, an instructive paper by him on "Deciduoma Malignum," read before that Society, having appeared in our last week's issue. He is also a corresponding member of the Belgian Society of Gynæcology, and an Honorary Fellow of the American Association of Obstetrics and Gynæcology. He is a Fellow of both the Edinburgh Colleges, and was recently elected President of the Royal College of Surgeons. Dr. William MacEwen was appointed to the Chair of Surgery in the University of Glasgow in 1890. He has earned for himself world-wide renown as a surgeon, and no one who was present can forget the enthusiasm with which his address on Cranial Surgery (a subject in which he is a pioneer) was received at the British Medical Association meeting in Glasgow about twelve years ago. He is a native of Rothesay, and a graduate of the Glasgow University, where he took his M.B. degree in 1869 and his M.D in 1872. One of his first official positions was that of Casualty Surgeon to the Glasgow Central Police Office, and he subsequently became a Lecturer on Systematic and Clinical Surgery, and a Surgeon to the Glasgow Royal Infirmary and Sick Children's Hospital. In 1896 he was invited (and acceded to the request) by the University of California to deliver a series of lectures on Surgery. The work by which he is best known is his "Pyogenic Diseases of the Brain and Spinal Cord" and his book on the "Pathology of Osseous Deformities of the Legs," in which the operation for knock-knee with which his name is associated is described.

Arsenic in Health and Disease.

Since the calamitous but now classic outbreak of arsenical poisoning in the North of England from the drinking of contaminated beer (The Medical Press and Circular, Nov. 28th, Dec. 12th, 1900), much attention has been devoted to the study of arsenic in its relation to normal and morbid processes. Professor Gautier, in Paris, has for long contended that arsenic should be considered a normal constituent of human tissues, and it has been shown that it may be detected in many animals. The medico-legal bearing of this is clearly manifest. The matter is now receiving much attention in Paris. Dr. Delèpine has recently carried out a series of experiments in which rats were given arsenical beer and other arsenical solutions. Although of interest they are of but little importance in elucidating the action of "dietetic" and "medicinal" quantities of arsenic on man. On these points there is need for much research. In a recent number (The Medical Press and Circular, May 21st, 1902), we referred to the startling suggestion that the partaking of arsenical beer might be considered a factor in the increase of cancer. But if arsenic is a more or less constant constituent of soot, as is certainly the case when some forms of coal are used, there seems some reason in the further suggestion which has recently been made that the external irritation of "arsenicated soot" might play some part in producing epithelioma or "chimney-sweeper's cancer." Certainly, as is urged in this month's "Polyclinic," it behoves the British profession to bestir itself in the investigation of the arsenic question. We are pleased to note that the matter is to be further discussed at the Manchester meeting of the British Medical Association. A convenient summary of the chief clinical features of the recent outbreak of poisoning from arsenicated beer appears in this year's "Medical Annual." We hope many will adopt Mr. Hutchinson's excellent suggestion, and send any facts relating to the arsenic question to the Medical Graduates' College, where, we understand, there is an organisation for the collection and publication of information on the subject. The material now being collected by the Royal Commission should also throw much new light on the *role* of arsenic in health and disease.

A Gaelic Medical Manuscript of the Sixteenth Century.

The greater part of the last number of *The Caledonian Medical Journal* is devoted to an examination of "A Gaelic Manuscript of 1563." The original is deposited in the British Museum, and has been catalogued as "Additional 15,582." This interesting article is from the pen of H. Cameron Gillies, M.D., who, very evidently, treats his subject *con amore.* It is illustrated by a series of photo-lithographic reproductions of ten of the most important columns; and the tyro is further instructed by a page which gives the most frequent contractions employed by the scribes. As Dr. Gillies truly observes, anyone who can read the specimens thus furnished can read the whole manuscript, and, indeed, all other similar ones. He has come to the conclusion that "the book belonged without doubt to the remarkable family of Highland physicians named Beatons or Macbeths, who are so famous in the medical traditions of the West and North of Scotland." Like all medical treatises of the time, the substance of the text is, admittedly, *not original.* The "authority" of Hippocrates, Galen, Avicenna, Rhases and others is produced on almost every page. The origin of the contents of some few of the most important items has been traced by Dr. Gillies to John of Gaddesden and to Guy de Chauliac, from whose pages they have been almost literally transcribed. Unsavoury remedies derived from the animal kingdom are necessarily well in evidence; but, as Dr. Gillies truly points out, their application does not contrast unfavourably with that of the *animal extracts* and the *antitoxins* of the present scientific age. The writer also points out that the language must be described as Gaelic, and not Irish—being "nearly the language of Argyll and the West to the present day." We cordially thank Dr. Gillies for the treat which he has afforded us in the perusal of the results of this investigation.

The Electrical Resistance of Blood and Urine.

For the past few years Dr. Dawson Turner, of Edinburgh, has from time to time investigated the electric resistances of human blood and urine in certain diseases, and has drawn interesting conclusions from his results, and the contrast obtained in each case with the healthy normal standards. On February 25th, 1902, the resistance of the blood of a patient, æt. 51, suffering from pernicious anæmia, and under the care of Dr. A. James in the Edinburgh Royal Infirmary, was found to amount to 300 ohms only, instead of the normal 550. The resistance of the urine, which was tested at the same time, amounted to 88 ohms instead of the normal 45. Similar results were reported by this observer in the "Proceedings of the Royal Society of Edinburgh," December 21st, 1891. "Hence we have the striking fact that, while the urine contains too few salts, the blood contains an abnormal amount. The kidneys, then, must obviously, be in fault." The blood resistance in diabetes mellitus is high, as is that of the urine. We believe that there is an instructive future pathway of science thus opened up by Dr. Dawson Turner.

Hernia and the American Cartridge Belt.

From the far-off Philippine Islands comes the groan of the American warrior, and the surgical report of his professional guardian. The physical grievance is hernia; which is, we are told, "the commonest surgical condition that confronts the military surgeon in the Philippines." A predisposition to this incapacitating condition is soon furnished by the emaciation which nearly always follows exportation of the American citizen to those recently acquired insular territories. This is, of course, accompanied by general loss of muscular tone; and the lowered standard is too often more demonstratively stamped by attacks of diarrhœa, dysentery, enteric fever, and their collateral accompaniments and inevitable sequelæ. "But the chief causal factor, it is believed, lies in the army cartridge belt." This is worn around the abdomen, supported only by its own constriction above the hips. The obviously mischievous effects of such an arrangement are further emphasised by the fact that the abdominal belt is a very favourite item of costume with the masculine American. "Even in 'route marching'—except when carrying extra ammunition—the cartridge belt is seldom swung from the shoulders." In almost every other army the abdominal cartridge belt has been discarded: the resulting item of contrast speaks unfavourably for the usually practical bias of the transatlantic genius.

The King and the Medical Profession.

In this time of suffering for the King and sorrow for his people it is pleasing to remember that his Majesty has not only always shown himself a loyal patient, but has ever taken a profound interest in the advance of medical science, and has oftentimes gone out of his way to do honour to the medical profession, while to not a few members of the healing art he has extended many evidences of his gracious interest in their efforts to alleviate sickness and prevent disease. We venture to think that to members of the medical profession there have been opportunities for such near approach to the royal presence that the King has not only learnt the personal value of his "medical advisers," but has understood in a special way the importance of maintaining efficient medical service for his poor and dependent subjects. All know of his Majesty's deep and untiring interest in our national hospitals and his efforts to secure their financial welfare. The King has on several occasions shown his intimate knowledge of the value of scientific research, and urged the necessity of solving the mysteries which still baffle our efforts to stamp out such diseases as tuberculosis and cancer. It is well also to remember that the King has delighted to honour the profession by himself becoming an Honorary Fellow of the College of Physicians and an Honorary Fellow of the College of Surgeons.

The Function of the Vermiform Appendix.

Much discussion has taken place regarding the function of the cæcal appendix. Sir Frederick Treves, writing in 1890, spoke of it as "obsolete and out-of-date," and said, "It is safe to predict that in the intestine of the man of the future there will be no such structure found hanging from the cæcum." The general opinion has been in favour of considering it as a vestigial structure, as an embryonic remain, a remnant of the evolutional past. Dr. Kelynack, in his book on the Pathology of the Vermiform Appendix says:—"The vermiform appendix is a constant structure in man. This is not so in the higher animals generally. It is said to exist as a distinct process only in the gorilla, chimpanzee, orang, and gibbon among the higher apes; but is uniformly present in the wombat. It would seem that the appendix in man and these animals really represents the lower portion of the cæcum, which in many of the lower vertebrates is of considerable size. As supporting this opinion, it is interesting to note that the cæcum in the monotremes is also small and worm-like. In the lemuroids it is long and drawn out into a somewhat conical termination." The vermiform appendix is rich in lymphoid elements and Dr. R. J. A. Berry and others have sought to show that such structures may play the part of "a cæcal tonsil," and thus be of considerable functional importance in the intestinal economy. There is, however, no reason to believe that those persons who have suffered the loss of their cæcal appendix are thereby in any way subjected to gastro-intestinal disability, for, at least in this country, excision of the vermiform appendix is only performed when there is evidence that it is the seat of morbid processes.

Abuse of Narcotics and Hypnotics.

We are glad to notice that a warning note against the abuse of hypnotics has been raised and re-echoed by our transatlantic professional brethren. The land of most advanced views of liberty, of most rapid movement, and of keenest competition, has received, and we believe deservedly, the credit of producing the largest proportion of victims to the use of narcotic and hypnotic medicines. It is a necessary effect of the continuous and merciless over-pressure, under the influence of which the pilgrimage of life is performed in the great junior republic. Reports of startling individual cases ever and anon appear—as it were to warn the panting races for the goal of material "success" of the terrible dangers which beset their path. In a recent number of the Chicago *Medical Recorder*, Drs. Church and Hutchinson have called attention to the deplorable, and of the fatal, results of the reckless use of trional and sulphonal. In commenting on the same subject Dr. Arthur W. Rogers, of Wanwatosa, Wisconsin, tells us of a remarkable specimen of idiosyncrasy "in the case of a young man—a morphine *habitué*—who with suicidal intent took at one time 180 grains of trional. This young man had been excessive in every possible way. He had used cocaine and morphine in large doses for months; he had drank one to two quarts of whisky daily for some time, and had taken the 'gold cure' three different times." Still his record-making dose of trional "gave rise to no critical symptoms." Verily, verily, the ambition of our transatlantic cousins is comprehensive and many-sided!

Bacteriology of Puerperal Fever.

It is usually held that sapræmia in puerperal women is due to the presence of putrefactive organisms in the uterus and vagina, and septicæmia to a lymphatic or blood infection with streptococcus pyogenes. Though this is doubtless true in the main, yet it is seldom accurate, for a careful investigation of the lochia during sapræmia nearly always shows the presence of pathogenic bacteria, even though few in number, and on the other hand, many other organisms may be associated with the streptococcus in septicæmia, or may even cause it independently. In an interesting paper read before the recent Inter-Colonial Congress at Hobart, Mr. Aynlasy enumerates some of the bacteria found in relation to septicæmia. Thus he himself has seen two fatal cases where the infliction was due to the colon bacillus, and out of 179 cases of puerperal fever investigated by Krönig, the gonococcus was found in fifty. Staphylococci have often been found in some, and among other organisms present have been the diphtheria bacillus, Frankel's pneumococcus and Welch's gas bacillus. From one case at the John Hopkins Hospital no less than four distinct bacteria were isolated — streptococcus, staphylococcus aureus, typhoid bacillus, and a gas-forming anaërobe. In practice an important point is that since antistreptococcic serum is useless where the infection is not that of the streptococcus, its apparent failure in so many instances is due to the fact that the infection is that of some other organism.

South Africa and Medical Practice.

Peace is the beginning of vast prosperity for South Africa. Even as we are now gladly welcoming the returning warriors, farewells are being said to the outgoing workers. At first hardships and possibly actual suffering will have to be borne by many. But the hope of future benefit will stop present grumbling. Already many young medical men are looking to South Africa as to a land of promise. A distinguished professor recently informed his students that he believed a great South African University would arise, with perhaps its centre at Pretoria, where there would be formed a great medical school. He showed that we were too crowded at home; that we were starving one another; that the rigid etiquette met with everywhere was due to the overcrowded condition of the profession at home, and he urged that there would be great openings for those men who cared to keep their eyes open. All this is no doubt in great measure correct, but we venture to urge the necessity for wise caution and delay in hasty procedure, especially to those who have neither friends nor funds. South Africa is but at the beginning of the making, and it is necessary for its prosperity that selfish aims should as far as possible be set aside, and that we send of our best to play a part in the building of this great land. In any case we trust medical men will uphold the highest traditions of the profession in South Africa, and maintain the highest code of ethics.

Hydatid Disease of the Lung.

Fortunately in this country hydatid disease of the lung may be considered a rarity. But this is not so in Australia. Dr. A. A. Sendon, of Adelaide, has recently published a valuable monograph on the subject, in which he shows it is possible to recognise several stages in a typical case of hydatid cyst of the lung. First, there is the period of latency marked by an absence of symptoms or by indecisive evidences, and sometimes ending in retrograde changes. Later, physical signs may be apparent, and the cyst may assume enormous proportions. The natural tendency is to rupture and expulsion of the contents. The ruptured cyst sometimes passes into a period of quiescence, and it may even become obsolescent. Often, however, expectoration of the mother cyst occurs. The patient may die of impaction of fragments of membrane in the glottis, may succumb to hæmorrhage, or may recover with a potential cavity. Unfortunately, in many serious sepsis occurs. Even after expulsion of the hydatid membrane the empty lung cavity may never altogether contract and lead to further complications. It is well that attention should be drawn to the pathology of hydatid disease of the lung, especially at a time when the visits of Colonials to this country are becoming more and more frequent, and when also we are realising that the old country should be made first acquainted with the nature of all morbid affections occurring in every part of the Empire.

The Straight-Fronted Feminine Corset.

Woman is nothing if not thorough. The main principle of her dress has always apparently been the exaggeration of facts, carried to an extreme degree, and then, as a rule, suddenly and absolutely abandoned. For instance, Nature has endowed shapely woman with an exquisite inward curve of the sides of the body above the hips. That "line of beauty," the phrase which Hogarth invented, probably with an eye to that particular curve, lovely woman has always spent her utmost ingenuity in endeavouring to improve. That weapon of torture, the modern corset, needless to say, has received the unsparing condemnation of all scientific authorities upon health and beauty. In spite of damaged organs and shortened lives, however, woman has insisted upon her own standard of beauty so far as "figure" is concerned, namely, that the test of excellence is one of size. Mere shapeliness as that of the Venus of Milo, does not count, for contour, as things go, is made to order by the milliner, and woman can defy the freaks of Nature with the aid of the *corsetière*. The latter ingenious craftswoman has now put the crowning touch on the virtues of the corset by decreeing that the front must be straight. In other words, the lower part of the abdomen, which hitherto has been allowed to keep a curved contour, capable of adapting itself to the varying capacity of the abdomen, is now to be straight as a plummet-line. This last vagary would be ludicrous were it not an outrage upon common sense and at the same time a wanton damage to female health.

The Regulations of the Madrid International Medical Congress.

In commenting upon the difficulties attending the organisation of the International Hygiene Congresses we have mentioned the lack of any means of restricting participation in these meetings to persons possessing some sort of scientific qualification, the absence whereof seriously threatens the success of these Congresses. In the International Medical Congresses, at any rate, some guarantee has been afforded that members are qualified medical men, but this salutary rule has been set aside by the organising committee at Madrid. We learn, indeed, that the membership will be extended to doctors, pharmaceutical chemists, dentists, veterinary surgeons "and other persons engaged in the practice of the various branches of medical science," and, as if this latitude were still too restrictive, admission is also accorded to persons "in possession of a scientific or professional title and to representatives of the press," that is to say, all the world and his wife. It follows that the Madrid Congress will not, like its predecessors, be a medical meeting exclusively composed of medical men, and it thus forfeits its distinctive character. We cannot but think that this departure from time-honoured precedent will jeopardise the success and the continuity of these international gatherings. The only object which the organisers can have had in view in thus violating the fundamental principle of these meetings must have been to increase the number of subscribing members, but in so doing we are convinced that they have been singularly ill-advised. Medical topics are ill-suited for debate before an audience largely composed of non-medical persons, whose presence is likely to have a deterrent effect on many medical would-be adherents.

The New Charing Cross Hospital Buildings.

The laying of the foundation stone of the new buildings at the Charing Cross Hospital suggests some comments as to the advisability of such structures, When complete the hospital will consist of a large roughly triangular, block with a well in the centre. What would happen in such a building in case of fire is a question that demands careful consideration. From recent experiences we know that the fire escapes provided by the Metropolitan Fire Brigade may fail to reach the upper floors at all. It would be useless to provide roof exits, for there would be no neighbouring roofs upon which to take refuge. It would be interesting to know what steps have been taken by the Charing Cross Hospital authorities to secure proper structural exits for persons inside the building in case of fire. It would be still more interesting to learn whether the Fire Brigade or the London County Council have inspected the building and made any suggestions as to fire extinguishing and life-saving appliances. A hospital requires no less protection than a theatre, but we doubt if the authorities take much, if any, trouble as regards the collections of sick people, although of late years they have looked more or less after the theatres. Some day a fire in a big hospital will awake the nation to a sense of their responsibilities in the matter.

The Diagnostic Value of Pupillary Changes.

In the course of investigations made with the object of determining the relationship between pupillary changes and the existence of syphilis, tabes and general paralysis, Dr. Dufour, of Paris, found that inequality of the pupils is a condition which, in the majority of cases, appeared to stand in no relationship to syphilis or to either tabes or general paralysis. The diagnostic importance of this abnormality is, therefore, small. Irregularity of pupil, on the other hand, justifies the assumption of a previous syphilitic infection or of the existence of one or other of the para-syphilitic diseases mentioned above. He never met with the Argyll-Robertson pupillary reaction except in conjunction with syphilis, tabes or general paralysis. It follows that the latter sign is one of considerable practical value, indicating as it does a functional disturbance of the posterior columns of the spinal cord, though this, it must be remembered, is not always of syphilitic origin.

Medical Service of Intercession for the Recovery of the King, St. Paul's Cathedral.

A SHORT special service of intercession has been organised by the Guild of St. Luke, at St. Paul's Cathedral, for this evening, July 2nd, at 7.30, on behalf of the whole medical profession. Admission to the space under the dome will be by tickets only. Tickets will be sent to all medical practitioners resident in London, and other doctors wishing to attend are asked to apply to the Registrar of the Guild, 24, Somerset Street, Portman Square, W. In order to make the service a public corporate act of intercession on behalf of the profession robes will be worn. It is intended to send a respectfully-worded message of sympathy to the Queen on behalf of those attending. The spirit of the service may be gathered from the text at the head of the invitations, "For they shall also pray unto the Lord that He would prosper that which they give for ease and to prolong life."

The Study of Altitude.

THE influence of altitude on physiological processes is well recognised. The importance of high health stations has long been known and many of the most renowned sanatoria are in elevated districts. The rarefied atmosphere of certain resorts is undoubtedly a factor of much value in the treatment of some cases. Blood changes and tissue alterations occur when a patient is transferred from low to high places. Even serious functional derangement is brought about by a quick passage to positions of high altitude. But much of our knowledge is fragmentary and all is incomplete, and we are therefore particularly glad to see that Professor Angelo Mosso has obtained from Queen Marguerite of Italy the use of her beautiful châlet on Mont Rosa, at an altitude of 13,000 ft., as a physiological laboratory for the study of the influence of rarefied natural air and altitude on animal life.

Travel as a Prophylactic Agent.

AT a time when the thoughts of many are turning to holidays, and many minds are preparing for tours, and extensive arrangements are being made for travel, it is well that the importance of travel should be clearly recognised not only as an educational advantage and delightful pastime, but as a most valuable prophylactic agent. If such a conception was more frequently recognised we venture to think that holidays would prove of much greater service in the maintenance of health and prevention of disease. Unfortunately the touring ground or holiday resort is only too often selected merely in accordance with fashion, caprice, or convenience, and with no clear idea of the value which judiciously selected and wisely planned travel is capable of accomplishing in strengthening mental and bodily powers.

THE Cremation Bill has passed "the Lords," and will probably have a safe journey through "the Commons," and so pass into law.

A SUICIDE epidemic is said to be prevailing in France, no fewer than twenty-four persons having taken their lives during a period of three days.

AN international golf match is being arranged for during the gathering of the British Medical Association at Manchester, and will be played on August 1st.

A SOCIETY has been formed in Germany for the prevention of venereal diseases on the lines of similar organisations for the elimination of tuberculosis and alcoholism.

THE annual temperance breakfast to members of the British Medical Association will be given by the National Temperance League at Manchester on Thursday morning, July 31st.

PERSONAL.

DR. STCLAIR THOMSON has been elected a corresponding member of the American Laryngological Association.

ON Thursday, June 26th, the Duke and Duchess of Aosta paid a visit of inspection to the Italian Hospital in Queen Square.

SIR CHARLES WYNDHAM, our new "knight-actor," once studied medicine, and during the American Civil War he served on the medical staff of the Federal Army.

IT is said that Major Ronald Ross, F.R.S., has declined the superintendency of the department of Tropical Medicine at the Jenner Institute of Preventive Medicine.

PRINCESS LOUISE to day (Wednesday, July 2nd) lays the foundation stone of the new building of the Victoria Hospital for Children, and will afterwards be present at the fête in the grounds of Chelsea Hospital.

SIR HENRY FREDERICK NORBURY, M.D., K.C.B., Director-General of the Medical Department of the Navy, has been Gazetted an Honorary Surgeon to His Majesty.

IT is particularly pleasing to the members of the medical profession to find that among the first holders of the new "Order of Merit" is Lord Lister. Scientists have also received due recognition in the persons of Lord Rayleigh, Lord Kelvin, and Sir William Huggins.

DR. JAMES MURRAY, late Medical Officer of the Prison at Wakefield, has been appointed Medical Officer of H.M. Prison at Birmingham. On leaving Wakefield he has been presented with various "tokens of affection and esteem" by his friends—presumably not by his patients.

THE CORONATION HONOURS.

The list of Coronation Honours, which was published on Thursday last, in spite of the disastrous circumstances necessitating the postponement of the Coronation ceremonies, is a long one, but the medical profession as a whole have every reason to be gratified with the distribution of titular distinctions, in respect of both number and selection.

Lord Lister has been made a member of his Majesty's Most Honourable Privy Council, and has been appointed a member of the new "Order of Merit."

Sir Frederick Treves, K.C.V.O., C.B., F.R.C.S., and Sir Francis Laking, K.C.V.O., M.D, have had baronetcies conferred upon them.

Among the Knights are :—

J. W. Collins, M.D., F.R.C.S.
Alfred Cooper, F.R.C.S.
Halliday Croom, M.D., President of the R.C.S.Ed.
Thomas Fraser, F.R.S., M.D., President of the R.C.P.Ed.
Victor Horsley, F.R.S., F.R.C.S.
H. G. Howse, President of the R.C.S.Eng.
Professor W. MacEwen, F.R.S., F.R.C.S.
Isambard Owen, M.D., Deputy Chancellor, University of Wales.
Thomas Myles, M.B., F.R.C.S.
William Whitla, M.D.
A. Conan Doyle, M.D.

Sir William Church, Bart., President of the R.C.P. Lond., has been appointed Knight Commander of the Order of the Bath.

The Hon. Frederick W. Borden, M.D., Minister of Militia, &c., of Canada, has been appointed Knight Commander of the Order of St. Michael and St. George.

In the Indian Services the Kaisar-i-Hind Gold Medal has been bestowed upon Capt. T. W. A. Fullerton, M.D., and Lieut.-Col. John L. Poynder, both of the Indian Medical Service, and Edgar Thurston, L.R.C.P., Superintendent of the Government Central Museum at Madras.

Order of the Bath.

Have been appointed in the Order of the Bath (Second Class, Military Division) :—

Inspector-General of Hospitals and Fleets J. D. Macdonald, M.D., R.N. (retired).
Surgeon-General John A. Woolfryes, M.D., C.B., C.M.G., Hon. Physician to the King.
Surgeon-General Annesley C. C. de Renzy, C.B, Indian Medical Service (retired).
Surgeon-General William Taylor, M.D., C.B., Hon. Physician to the King.

Third Class—Military Division.

Fleet-Surgeon James Porter, M.D.
Lieut.-Col. Patrick F. O'Connor, Indian Med. Service.
Lieut.-Col. Sir James R. A. Clark, R.A.M.C. (Militia).
Lieut.-Col. G. T. Beatson, M.D., R.A.M.C. (Volunteers).
Col. J. D. Edge, M.D., R A.M.C.
Lieut.-Col. W. A. May, R.A.M.C.

Second Class—Civil Division.

Duncan Hilston, M.D., Inspector-General of Hospitals and Fleets (retired).
Robert Grant, M.B., Inspector-General of Hospitals and Fleets.

Distinguished Service Order.

Lieut.-Col. H. J. McLaughlin, M.D.
Lieut. Col. C. E. Nichol, M.D., R.A.M.C.
Major H. A. Thompson, M.D., R.A.M.C.
Major W. H. W. Elliot, M.B., Indian Medical Service.

Companions of the Order of St. Michael and St. George.

Lieut.-Col. H. Charlesworth, R.A.M.C.
Major W. G. Macpherson, R.A.M.C.

Special Article.

A FORGOTTEN MEDICAL WORTHY.

By George Foy, M.D., F.R.C.S.

One of the bravest and most accomplished of the adventurous seamen who went forth to war against Spain in the South Sea was Surgeon Lionel Wafer, the principal medical officer of the company of privateers that followed William Dampier and afterwards the still more famous Davis. Of his parentage and place of birth nothing is known with any certainty, and it is no more than an approximation to the truth to fix the date of his birth in 1660. From his own writings we know that he "was still young" when in 1677 he shipped as surgeon's apprentice to the surgeon of the *Great Anne*, of London, under Captain Zachery Browne, bound for the West Indies. In the *Great Anne* he visited Java, Sumatra, and Malacca. When in Bantam, Batavia, he was on shore when the ship sailed for England. He got a passage home, and arrived in England in 1679. Soon afterwards he shipped for the West Indies as surgeon's mate, and on the arrival of the vessel at Jamaica he deserted, going to join his brother, who was an overseer of a sugar plantation of Sir Thomas Mogford. He commenced practice as a surgeon at Port Royal, and some three months after was persuaded by Cook and Lynch to join their expedition against the Spaniards. Shortly after Christmas the privateers, commanded by Cook, Lynch, Sawkins, Coxon, and Sharp, sailed for the bay of Nombre de Dios, and at the Bastimantos met with Dampier, and, in his own words, "having mustered our forces at Golden Island, and landed on the isthmus, we marched overland and took Santa Maria, and made those excursions into the South Sea which Mr. Basil Ringrose relates in his history." The company numbered some 350 men, and they arrived at the shore of the Pacific Ocean, on which they launched in Indian canoes and periagoes. They were fortunate enough to capture a Spanish vessel, and in her they stood away to the southward as far as Juan Fernandez. Sawkins was dead, and his successor Sharp was deposed by Watling. Dissensions broke out. Dampier, Wafer and others were dissatisfied with Sharp, and took to the long boat and the canoes and made for the isthmus of Darien, "choosing to go back again a toilsome journey overland, than stay under a captain in whom we experienced neither courage nor conduct." The company following Dampier and Wafer consisted of forty-four white men, who bore arms, a Spanish-Indian, who bore arms also, and ten Mosquito-Indians. They landed at Cape Lorenzo, and sunk their boats and began their march across the difficult country, directing their course by their pocket compasses. The difficulties they had to encounter were very great, the isthmus chiefly consisting of pathless forests, deep rivers, torrents and mountains of the rudest description. During the greater part of their journey the rain descended in torrents, making the rivers and even the brooks impassable, and frequently obliging them to stop. At one of their halts, made to dry their clothes, firearms and ammunition, Wafer, was sitting on the ground near a man who was drying some gunpowder on a silver plate, who carelessly allowed it to get overheated. The powder exploded and scorched Wafer's knee to that degree that the bone was left bare, the flesh being torn away and the thigh burnt for a great distance above it. This dreadful accident took place on May 5th, 1681, and for a few days afterwards Wafer made shift to get on. The company allowed him a slave to carry his things, "being," as Dampier writes, "all of us the more concerned at his accident because liable ourselves at every moment to misfortune, and none to look after us but him." On the fifth day the slaves ran away, and the negro appointed to attend on him made off with his medicine chest, clothes, and so forth. He now took leave of his companions, and "set up his rest among the Darien Indians." But he was not left friendless, "for there staid with him one Richard Jopson, who had served an apprenticeship to a druggist in London; he was an ingenious man, and a good scholar; he had with him a Greek Testament, which he frequently read, and would translate into English to such of the company as were disposed to hear him." As he had no medicines, and as his wounds were very painful, he put himself in the hands of the natives, as did three wounded sailors who had also remained behind, who undertook the cure, and effected it in twenty days, by daily applying "some herbs which they first chewed in their mouths to the consistency of a paste, and putting it on a plantain leaf, and laying it upon the sore." In other respects the Indians were not so kind, only throwing him and his companions unripe plantains for food, "as you would throw bones to a dog." Some of the tribe had gone with Dampier as guides, and the Indians feared these guides had met with foul play, for they had not returned within the time they were looked for. One morning they prepared a great pile of wood, and told Wafer that he and his companions must expect to be burned on it when the sun went down, if the guides were not returned. At this time Lacenta, the chief of the Indians, happened to pass that way, and dissuaded the enraged people from their purpose. Wafer and his companions were then sent with two Indians to the Atlantic coast, but the Indians left them in the woods, where for eight days they wandered, feeding on berries and roots, and at last they found a track out of the woods, which, however, led them into the very camp they had left. But the guides had returned to their tribe, and Wafer and his companions were welcomed and hospitably entertained, and then conducted to the camp of their chief, the merciful Lacenta. It was the rainy season, and the chief detained them until the dry season commenced. During this interval the surgical ability of Lionel Wafer raised him to the highest honours Lacenta could bestow. One of the chief's wives fell sick and bleeding was prescribed. Wafer thus describes the Darien Indian mode of venesection:—"The patient is seated on a stone in the river, and one with a small bow shoots little arrows into the naked body of the patient, up and down, shooting them as fast as he can, and not missing any part, but the arrows are gagged, so that they penetrate no further than we generally thrust our lancets." Wafer, seeing the Indian method caused the patient much pain, volunteered to bleed the lady, which Lacenta consented to; but after the incision made by the lancet, when the chief saw the blood spout out in a stream, instead of falling drop by drop as it did in their method, he laid hold of his lance, and swore by his teeth (the most solemn of their oaths) that if his wife did not recover he would kill him. It was seen, however, that the stranger's mode of bleeding was better than their own, and when his wife recovered from her fever, Lacenta came, and before all his train bowed and kissed the surgeon's hand. Then writes Wafer: "The rest came thick about me, and some kissed my hand, others my knee, and some my foot; after which I was taken up in a hammock and carried on men's shoulders, Lacenta himself making a speech in my praise, and commending me as much superior to any of their doctors. And thus, afterwards, I was carried about from plantation to plantation, and lived in great splendour and repute, administering both physic and phlebotomy to those that wanted." Luckily for Wafer, he had a case of instruments wrapped up in an oilcloth and in his pocket when the negro decamped with the rest of his effects. Lacenta now was unwilling to allow Wafer to leave them, and it was only by promising to go to England and return with a pack of hunting dogs that the surgeon got away. An Indian escort of seven stout men was then granted, and four women to carry provisions. His wardrobe was sadly reduced, consisting only of "a linen frock and a pair of breeches." "These," he says, "I saved to cover my nakedness if ever I should come among Christians again, for at this time I went naked as the savages, and was painted by their women." He eventually reached the coast and was taken on board an English sloop at Le Sounds Key. In one of these ships was Dampier, with many of their old companions in the South Sea and in the disastrous journey across part of the isthmus. The four seamen, not being honoured like the surgeon, were probably not disguised by paint and Indian ornaments, they were presently recognised and heartily welcomed by their old shipmates. "But I," says Wafer, "sat awhile cringing upon my hams among the Indians, after their fashion, painted as they were, and all naked but only about the waist, and with my nose piece hanging over my mouth. I was willing to try if they knew me in this disguise, and 'twas the better part of an hour, before one, looking more narrowly upon me, cried out, 'Why, here's our doctor!' and immediately they all congratulated my arrival among them." In his diary he writes: "Foreseeing a necessity of wading through rivers frequently in our land march, I took care before I left my ship, to provide myself a large joint of bamboo, which I stopped at both ends, closing it with wax so as to keep out any water. In this I preserved my private and other writings from being wet through. I was often forced to swim." He was with Dampier in the sloop for some months in the West Indies. He again joined Dampier in Virginia, in August 1683, and with Cook sailed for Africa and the Pacific. After Cook's death Wafer remained with Davis and returned with him to the West Indies, where they received the King's pardon. Returning to England in 1691, he settled down in London where he is supposed to have died in 1705.

It has been well said that to the accidental detention of Lionel Wafer, we are indebted for one of the most interesting accounts of savage life that has ever been written—one of the most delightful books.

It should also be remembered that he saw how much the possession of Central America would facilitate communication with the East Indies, and in 1704, in the second edition of his book, with a dedication to the Duke of Marlborough, he makes a strong appeal to the Government to make a settlement on the isthmus whereby, among other advantages, "A free passage by land from the Atlantic to the South Sea might easily be effected, which would be of the greatest consequence to the East India trade."

It is much to be regretted that the work has not been reprinted in England; translations in almost every European language have appeared, and yet to English readers Wafer's book is unattainable, even though he has been the Livingstone of Central America.

ON THE PROMPT CURE OF ECZEMA, SYCOSIS IMPETIGO, AND ALLIED DERMATOSES BY FORMALIN.

To the Editor of The Medical Press and Circular.

Sir,—No doubt many of your readers have cases of impetigo and of sycosis under their care. Both of these diseases are prone to attack the face. They are very disfiguring, and both at times prove to be extremely intractable. I feel sure, therefore, that the suggestion of a safe and prompt remedy will be welcomed.

First, as to *impetigo contagiosa*. Both the streptococcus and the staphylococcus have been found to be present. The latter is undoubtedly the true causative agent, as indeed it is of *sycosis vulgaris* or *coccogenica*, the commoner of the two chief varieties of barber's itch. Dr. Sabouraud, of Paris, a dermatologist of the very highest reputation, stated at Cheltenham last year that sulphur, cade oil, and mercury are the best germicides for destroying the staphylococcus. But there is a far more reliable germicide than these; it is formaldehyde. See the remarkable series of experiments of Slater and Rideal (*Lancet*, April 21st, 1894, Vol. I, p. 1,004.) Formalin, which is a somewhat unstable solution of formaldehyde, varying from 35 to 40 per cent., appears to be not only a germicide but a reliable antitoxic, somewhat resembling salicylic acid, but more vigorous in its action. Glutol, which is a loose combination of formaldehyde and gelatine, occurs as a non-poisonous white powder, largely used by surgeons for dusting over a foul ulcerating surface in order to cleanse it and to control suppuration. In any form of facial pustulation, glutol may be freely applied to the skin, say, after each meal; in this kind of case vaseline and greasy preparations are strongly contra-indicated. Washing and fomenting are to be strictly forbidden, as these favour the growth and spreading of the coccus. Glutol has this decided advantage in the case of children, that it is not poisonous, even if introduced into the mouth. A convenient formula for ordinary examples is:—

Glutol, ʒj;
Pulv. Talci ad, ℥j.

Some surgeons order undiluted glutol in very severe cases of suppuration. In prescribing for skin disease, however, nothing like so strong a preparation is needed. For Slater and Rideal found that the development of *S. pyogenes aureus* is much delayed by so incredibly minute a trace as 1/20,000! whilst the microbe, when exposed to the action of 1 per cent., *perished in less than one hour!* I have used formalin in the various dermatoses induced by the staphylococcus, and have been greatly gratified by its prompt and permanent action. My clinical rule is, for *dry* eczema use *wet* formaldehyde; for *wet* eczema use *dry* formaldehyde, *i.e.*, glutol.

Among the oozing dermatites, in which it is useful, are *eczema madidans, impetigo, orificial pruritus,* and *sycosis vulgaris.*

Among the dry varieties are *ecthyma, eczema foliaceum,* and *erythema siccum.* All usually induced by the same coccus, viz., *S. pyogenes aureus.*

A distinct improvement is visible next day if this remedy is going to do any good. I can strongly recommend it to my professional brethren.

Finally, in that very troublesome condition, *pruritus ani* of the aged, I have seen great and immediate relief obtained by the following formula:—

Formalin, ♏5;
Liquor thyroidei, ʒj;
Ceratum Galeni (cold cream) ad ℥j.

I am, Sir, yours truly,
Edward Blake, M.D., M.R.C.S.Eng.
Berkeley Mansions, Hyde Park, W.

BROOKS ON "THE ELEMENTS OF MIND."

To the Editor of The Medical Press and Circular.

Sir,—In your review of my book "The Elements of Mind," the reviewer says:—"His first original (?) observation is that vices and virtues differ not so much in kind as degree, so that virtue may, under given circumstances, become a vice and *vice versa.* Well, that is hardly an acquisition to our knowledge, and had our author read even a little he would not have been at the pain of discovering the platitude."

Will you permit me to say, in justice to myself, that I made no claim to originality with respect to the above, and if you will turn to p. 4 of my book you will find these words:—"I do not claim originality for the idea (in the Prologomena) that there is no evil in man's nature, and that good is only the mean between two extremes, for Aristotle advances a very similar conception." I am, Sir, yours truly,

H. Jamyn Brooks.
17a, Radnor Place, Hyde Park Square, W.
June 28th, 1902.

GARLIC IN PHTHISIS.

To the Editor of The Medical Press and Circular.

Sir,—The offensive odour of garlic and other plants of the onion family has been urged as a drawback to the use of this remedy, if remedy it be, in consumption. I would point out that parsley, if taken at the same time, very greatly mitigates the characteristic emanations, and I would suggest its use by those who are giving, or propose to give, this method a trial.

In making this suggestion, I do not wish to convey the idea that I consider this treatment—or any other—likely to prove of permanent benefit in such a disease as phthisis; indeed, the laudation so readily bestowed upon these various "treatments" seems to me to savour of mediævalism—of a time when drugs were everything and the *vis medicatrix naturæ* nothing.

I am, Sir, yours truly, M.D.

Literature.

FOX'S ATLAS OF SKIN DISEASES. (*a*)

This valuable and interesting work has been undertaken on new lines, namely, that of coloured photography. The results are on the whole excellent, although here and there are affections of the skin that obviously do not lend themselves to that form of artistic representation. In the treatment of diseases of the skin a correct diagnosis is a matter of vital importance, and in no other branch of medical work is the diagnostic faculty more dependant upon objective appearances. Hence the generally recognised value of illustrated atlases as an aid to the study of dermatology. In some cases a careful inspection of Dr. Fox's beautiful plates could not fail to leave a lasting and complete record upon the mental retina of the student. No one, for instance, could mistake a case of herpes zoster after a careful study of the lifelike illustration of shingles. Another striking picture is that of urticaria graphica, in which the word "urticaria" is seen written in a raised wheal across a patient's shoulders. Dermatitis venenata resulting from the use of chrysarobin is likely not only to give a good visual representation of the occasional violent irritant results of that drug when applied to the skin, but also to impress one with a due sense of the risks attached to the use of that drug. A good idea is afforded of the multiform and widespread lesions caused by scabies in a child. In the last-mentioned plate the details are better seen with the help of a magnifying glass. In all Dr. Fox has selected a hundred different typical diseases of the skin for illustration. He has supplied a clear and concise text description of each malady and its appropriate treatment. In this part of his work he has shown some originality, and has kept in view the wider aspects of medicine involved in dermatological practice. The Lippincott Company may be congratulated upon the excellent tone and appearance of this publication, which should be on the bookshelf of every dermatologist.

ANTENATAL PATHOLOGY. (*b*)

Professor Ballantyne's book is, perhaps, the most important medical work which has appeared during the past year. The author has tackled a subject which, though by no means new to him—for he has worked at it for twenty years or more—is almost untouched by medical writers. And, as a result of his labour, the medical profession has placed before them an original work of great merit and of extreme practical importance. Professor Ballantyne had hoped to have been able to present to his readers in one volume the whole subject of antenatal pathology and hygiene, but, as perhaps might have been expected, he found that it was impossible to do so and at the same time to accomplish his desire of exhaustively discussing his subject. In consequence, in the present volume, he deals exclusively with fœtal physiology and pathology, and he has left the subjects of teratology and morbid heredity for a companion volume.

The volume before us contains two books. The first of these deals with the subject of "antenatal in relation to postnatal and neonatal pathology," and the second with "the pathology and hygiene of the fœtus." In short it contains blended into a homogeneous form Professor Ballantyne's former work on this subject—work which has been already to some extent laid before the medical world in some two hundred and odd communications, and which is now supplemented by reference to the work of others which has appeared in contemporary literature. In the first book, the birth and gradual growth of antenatal pathology are traced, and its relation to other

---

(*a*) "Photographic Atlas of the Diseases of the Skin." By George H. Fox, M.D. In Sixteen Parts. Philadelphia and London: Lippincott Company. 1901.

(*b*) "Manual of Antenatal Pathology and Hygiene: The Fœtus." By J. W. Ballantyne, M.D., F.R.C.P.E., F.R.S.Edin., Lecturer on Midwifery and Gynæcology, Medical College for Women, Edinburgh. Edinburgh: William Green and Sons. 1902. Pp. 527; 14 coloured plates and 55 figures).

branches of study—general pathology, biological sciences, &c., and its effect on neonatal pathology are discussed. In the second book, the anatomy and physiology of the fœtus are first discussed, and then the wide subject of fœtal pathology. The chapters which deal with the last named subject are to our mind the most important in the book, and in his endeavour to clear up and to systematise it, the author has done an essential service to medical science. Space forbids us to enter into a discussion on the many points which are raised, and indeed, even if there was space, it would be a venturesome reviewer who would tackle the author on his own ground.

There are many excellent illustrations, and those of fœtal ichthyosis are especially good. To the cases which Professor Ballantyne relates, we may be pardoned for adding one, which occurred in our own practice, in which the fœtus was born alive and very closely resembled that portrayed in Fig. 36. The mother was quite free from any form of skin disease. It was her second pregnancy, but the first had terminated in the occurence of a three months' abortion. The fœtus only lived a few hours.

Professor Ballantyne's work is essentially a work of reference, and for this reason we cannot consider the term "manual" a suitable one by which to designate it. A "manual" on any subject connotes a work in which a due proportion is observed between the practical importance of the subject discussed and the time which the average reader can devote to the study of that subject, The work before us pertains more closely to the nature of a treatise, in which every object is subordinated to the importance of presenting the fullest possible description of the subject. Whether Professor Ballantyne's work would be of greater value to the average reader if it partook more of the nature of a manual, is a matter into which we shall not enter. However that may be, it is a perfect work of reference for the specialist.

The companion volume, which, we trust, will soon appear, will be looked for eagerly by all who have studied the present volume. An instructive—we use the term advisedly—work on teratology has long been wanted, and if there is any medical writer who can produce such a work it is Professor Ballantyne.

A word of praise is due to the publishers for the excellent manner in which the present volume has been turned out. Paper, illustrations, and type are all alike as good as could be, and that, we regret to say, is not a compliment which can be paid to all British medical works.

ESSAYS BY THE LATE SIR JAS. PAGET, BART. (a)

WE are indebted to Mr. Stephen Paget for collecting and publishing under one cover selected essays and addresses of his father, the late Sir James Paget, Bart.

The volume should be read by every medical practitioner, containing as it does a vast amount of information of a kind one does not meet with in text-books, but which is essential for successful practice.

We have here in his own clear words, a description of that disease of the nipple which is associated with his name; the "stammering" of various organs; neuromimesis, and osteitis deformans.

The chapter on sexual hypochondriasis will not afford any satisfaction to a morbid curiosity, but will well repay the careful perusal of every medical practitioner, containing information derived from an unrivalled experience and keen observation, which will be an invaluable help in answering and advising on the innumerable questions raised by hypersensitive patients. These are matters of the utmost importance, but of the greatest difficulty; they are not dealt with in ordinary text-books, yet are constantly cropping up in study practice; in dealing with them experience is necessary, and we have that of many years, condensed here in a few short, lucid passages.

If we qualified our praise of the book at all, it would only be a slight regret that some few papers of a more or less popular nature are bound up with a majority which are essentially scientific. These, however, will be welcomed by many as affording a variety of reading and food for thought off the hard direct lines of pure medicine.

Medical News.

National Society for Employment of Epileptics.

A GARDEN PARTY will be held at the Colony for Epileptics, Chalfont St. Peter, Bucks, on Wednesday, July 9th, in order to afford an opportunity for visitors to see the colonists and their surroundings under every-day conditions. To this end it has been so arranged that during the earlier part of the afternoon (till 4.30) the colonists will be engaged in their usual work in the farm, the gardens, and the workshops, after which a cricket match and various other games will be played, and the Colony band will perform a selection of music.

A Locum Tenens Sentenced.

J. CREAN, *alias* William Waddell More, who, as already stated, was under remand on a charge of stealing jewellery from his principal at Bridlington (Yorks), was last week sentenced to three months' hard labour at the Petty Sessions.

An Edinburgh Tragedy.

MR. W. IVESON MACADAM, Professor of Chemistry at the Royal College of Surgeons, Edinburgh, was shot dead by a porter of the institution on the 24th ult., and his assistant, Mr. James Ray Forbes, received a fatal wound. The murderer was subsequently arrested.

British Medical Association Meeting.

WE are asked to announce that a meeting of members of the Association will be held in London, at St. Martin's Town Hall, on Tuesday next, at 8.30 p.m., "to take into consideration what action shall be adopted towards the Reconstitution Report and the disabilities it will inflict on the general body of members." These are:—Deprivation of powers now possessed through the annual meeting, and deprivation of sufficient representation through the branches, and the large increase of subscription.

Pass Lists.

University of Dublin (Trinity College).

School of Physic.—The following passed the Final Examination during Trinity Term, 1902 (Section A), arranged in order of merit:—Michael J. M'Auliffe, Henry Stokes; Herbert Stone, Douglas B. Thomson (æq.); Thomas C. A. Sweetnam; Harold T. Marrable, Philip S. Stewart (æq.); Frederick W. Bury, James F. F. Walsh, Cecil J. Wyatt; Thomas King-Edwards, George S. Walton (æq.); Thomas Ryan.

School of Physic.—Class Examinations, June, 1902—Practical Histology—First prize: H. English, 78½ per cent.; Second prize: J. Pringle, 76 per cent. First-class honours: G. M. Millar, 73·1·3 per cent. Honours: W. J. Powell, 69 per cent.; G. E. Nesbitt, 68 per cent.; M. D. Ferguson, 66 per cent.; A. G. Alexander, 65 2·3 per cent.; J. W. Burns, 64 2·3 per cent.

TRINITY TERM, 1902.

The following is the result of the Medical School Sizarships Examination:—

Half M.B.—Botany and Zoology—Anderson, E. C. Stoney; Cobb and Wright equal; Alexander and Atkinson, equal; Coppinger, Otway, Talbot-Crosbie; Beatty and Brook equal; Tomb, Peyton; Holmes and Vickery equal; Bate and Johns equal: Nicholson and Torrens equal; Crawford and Sherlock equal.

Half M.B.—Physics and Chemistry—Seymour, Coppinger, Marks, Sands, Cobbe, and Oldham passed on high marks; Sumerville, Tomb, and Woodroffe, equal; Haughton, Thompson, Connell, Conyngham; Beatty and Kenna, equal; Holmes and Jackson, equal; MacFarlane and Vickery, equal; Brook and M'Caul, equal; de Courcy, Gibbon, and Millar, equal; Drennan, Peyton, and Phelan, equal.

(a) "Selected Essays and Addresses." By Sir James Paget. Edited by Stephen Paget, F.R.C.S. London: Longmans, Green and Co. 1902.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ACCEPTED PAPERS, LECTURES, AND CASES.

The following are hereby acknowledged :—

"A Case of Internal Hydrocephalus in the Adult, simulating Cerebral Tumour." By W. B. Warrington, M.D., M.R.C.P. (Liverpool).

"A Case of Ascending Paralysis." By Alfred R. Parsons, M.D., F.R.C.P. (Dublin).

"The Normal Fundus as seen in the Ophthalmoscope." By E. Kenneth Campbell, M.B., F.R.C.S. (London).

"Notes on a Case of Osteoid Chondro-Sarcoma of the Liver, Treated by Disarticulation of the Hipjoint." By C. Yelverton Pearson, M.D., F.R.C.S. (Cork).

"Palatal Paralysis." By Docent Professor S. Erben (Vienna). From our Vienna Correspondent.

"Spinal Changes in Muscular Defects." By Professor H. Obersteiner. From our Vienna Correspondent.

DR. EDWARDS.—An article on the subject to which you refer is unavoidably crowded out, but will appear in our next.

SIR SHERLOCK HOLMES.

Among the men whom the King has delighted to honour, special mention should be made of Dr. Conan Doyle. Sir Conan Doyle is one of our most popular novelists, but readers of his works can never forget that he is at heart a doctor. His splendid service in South Africa and his able defence of the English army has shown moreover, that he is a true patriot. We gladly welcome Dr. Conan Doyle to the gallant gathering of medical knights.

OXONIENSIS.—The wiser course in sending a patient to a specialist under the circumstances you mention, is to ask whether he thinks it advisable or not for the patient to carry out treatment under his own private medical attendant; otherwise the specialist may take the patient under his care for a long period of time. In our own experience we have known of much heart-burning that could have been avoided by adopting the straightforward course above mentioned. A letter to a specialist must always draw an answer, and in professional relations of the kind involved the best of all guiding principles is that expressed in the old saw "prevention is better than cure."

L. B.—Yes.

THE HOSPITALS AND "THE CORONATION."

The hospitals on the route of the Royal Processions expected to gain much for their exchequers. The postponement of the Coronation has blighted all these hopes. It is said that St. George's and the Westminster were on the way to clear £10,000 after paying all expenses. At St. George's, 2,000 seats were let for a total of about £12,000. At Westminster Hospital 1,500 seats were let, realising about £12,000. At Charing Cross Hospital about 500 seats were let. It is to be hoped that purchasers will realise that the profits were to be devoted to a good purpose and will see that the hospitals do not suffer from the unfortunate event which was beyond the power of any to prevent.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, JULY 2ND.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Mr. Doran and others. Short Communication on a Case of Puerperal Eclampsia, with Autopsy and Remarks by Dr. R. H. Bell. Papers:—Mr. J. W. Taylor: (1) Complete Inversion of Uterus requiring Operation; (2) Ovarian Tumour obstructing Delivery, Vaginal Ovariotomy.

THURSDAY JULY 3RD.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 p.m. Annual General Meeting. Election of Officers.

RONTGEN SOCIETY (20, Hanover Square, W.).—Annual General Meeting. 8.30 p.m. Election of Officers and Council.

FRIDAY, JULY 4th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Meeting 8.30 p.m. Card specimen by Major M. T. Yarr. Papers:—Mr. Charles Higgins, Mr. Ernest H. Cartwright and Mr. Sydney Stephenson.

THURSDAY, JULY 10TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover, Square, W.).—8 p.m. Short Papers will be read by Mr. Bowreman Jessett and Dr. Hodgson. Specimens will be shown by Mr. Jessett, Dr. Hodgson, Dr. Purcell, and others.

Appointments.

BELL, THOMAS, M.D.Glasg. Certifying Surgeon under the Factory Act for the Shepshed District of Leicestershire.

CROCKER, J. M., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Bingley District of Yorks.

GARBUTT, R. H. O., L.R.C.P. & S.Ed., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Wolsingham District of County Durham.

HENEGHAN, P. J., L.R.C.S.I. and L.M., Certifying Surgeon under the Factory Act for the Foxford District of County Mayo.

HORNE, MAYNARD, M.A., M.B., B.C.Cantab., M.R.C.S., Assistant Anæsthetist to the Hospital for Women, Soho Square, London.

LEE, ROWLAND, M.B., B.Ch., B.A.O., R.U.I., Assistant Medical Officer at the Cardiff Workhouse.

LEWIS, S. T., Certifying Surgeon under the Factory Act for the Youlgreave District of Derbyshire.

MAXWELL, W. W., M.B., Ch.B.Edin., M.R.C.S., L.R.C.P.Lond., Senior House Physician to King's College Hospital.

MORGAN, W. E., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Union of Camberwell.

NOLANS, FRANCIS, F.R.C.S.I., Surgeon Medical Officer to the Irish Coastguards of North Wexford.

PRITCHARD, S. C., M.B., Ch.B.Edin., Junior House Physician to King's College Hospital.

REID, R. W., M.B., Ch.B.Aberd., Assistant House Accoucheur to King's College Hospital.

SHEARER, WILLIAM, M.B., Ch.M.Glasg., Medical Officer and Vaccinator for the Western District of the Parish of St. Andrew's.

STEELE, KENNETH, M.R.C.S., L.R.C.P., Anæsthetist to the Seaman's Hospital Society, with duties at the *Dreadnought* Hospital at Greenwich.

THOMSON, W. ERNEST, M.A., M.D., L.F.P.S.Glasg., Ophthalmic Physician to the Glasgow Maternity Hospital.

Vacancies.

County of London.—Medical Superintendent of the Epileptic Colony Asylum, Horton, Surrey. Salary £500, rising to £600 with house, rates, taxes, and water free. Applications to R. W. Partridge, Esq., London Asylums Committee Office, 6, Waterloo Place, S.W. (See advt.)

Hereford County and City Asylum.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications, with full particulars, to the Medical Superintendent.

Lanark County Council.—Assistant Medical Officer of Health. Salary £140 per annum, with travelling expenses. Applications to the County Medical Officer, Hamilton, N.B.

London County Asylum, Colney Hatch.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Age not to exceed 30. For forms of application see advt.

Mercers Hospital, Dublin.—Resident Medical Officer. Immediate application to John Robinson, Registrar. (See advt.)

Parish of Birmingham.—District Medical Officer. Salary £350 per annum. Applications to Walter Bowen, Clerk, Parish Offices, Edmund Street.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings. Applications to the Chairman of the Selection Committee at the Hospital.

Royal Dental Hospital of London.—The Curatorship to the Mechanical Department. Salary £200 per annum. Applications to Morton Smale, Dean, 32, Leicester Square, London, W.C.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications to the Medical Superintendent.

Travelling Representatives.—Manufacturing Firm of Druggists require Travelling Representative for India, the Colonies, Continent and Home Districts. For full particulars as to Age, Salary, &c. (See advt.)

West Kent General Hospital, Maidstone.—House Surgeon. Salary £120, with board and residence. Applications to the Secretary.

Births.

BRISTOWE.—On June 24th, at The Cottage, Wrington, the wife of H. C. Bristowe, M.D., of a son.

CARR.—On June 27th, at 19, Cavendish Place, London, W., the wife of J. Walter Carr, M.D., of a daughter.

GLADSTONE.—On June 25th, at Clarendon Villa, Newton Ferrers, near Plymouth, the wife of Arthur Edward Gladstone, B.A. Cantab., M.R.C.S., L.R.C.P., of a son.

WYLLYS.—On June 29th, at 53, Fellows Road, Hampstead, the wife of Henry Wyllys, F.R.C.S.E., of Great Yarmouth, of a son.

Marriages.

BLAKE—MCCULLOCH.—On June 18th, at Edinburgh, Dr. T. F. Hillyer Blake, second son of T. W. Blake, M.D., of Bournemouth, to Isabel McDonald McCulloch second daughter of John and Mrs. McCulloch, of Edinburgh, N.B.

BLUE—RHODES.—On June 24th, at St. Peter's Church, Birstal, Charles Blue, B.A., M.B., of Boosbeck, Skelton-in-Cleveland, to Alice Mary, eldest daughter of the late Wilcock Rhodes, of Brier Hall, Gomersal.

Deaths.

EASTON.—On June 19th, at Alnwick, George Frederick Easton, M.D., of Cournace Hill, Dumfries, aged 83.

FFOLLIOTT.—On June 27th, at 13, Woodland Gardens, Muswell Hill, Deputy-Surgeon General Nicholas Ffolliott, A.M.D., aged 71.

GEE.—On June 27th, at 90, Carleton Road, N., Thomas Ernest Gee, F.R.C.P. Edin., of 67, Westbourne Park Road, London, aged 48, second son of the late William Gee, of Southwell.

SCOTT.—On June 26th, at his residence, Iver, Bucks, of heart failure, John Harrison Scott, M.B., F.R.C.S.I., younger son of the late William Scott, Rathmines, Dublin.

"SALUS POPULI SUPREMA LEX."

VOL. CXXV. JULY 9, 1902. No. 2.

Original Communications.

THE NORMAL FUNDUS AS SEEN WITH THE OPHTHALMOSCOPE.

By E. KENNETH CAMPBELL, M.B.ED., F.R.C.S.ENG.,

Surgeon to the Western Ophthalmic Hospital: Surgeon-Oculist to His Highness the Maharajah of Baroda.

DEFINITION (fundus = foundation).—The term fundus may be defined as the cup-shaped hollow of the sclerotic, pierced behind by the termination of the optic nerve, and lined by two superimposed layers, the choroid and retina.

Anatomical.—The sclerotic is to be regarded as an extension of the dura mater; the choroid, of the pia mater; and the retina, of the brain.

The sclerotic is a dense, unyielding, white, fibrous-tissue tunic continuous with the dura mater.

The choroid is composed of a richly vascular loose connective tissue web, the cells of which contain abundant pigment, *so as to insure the internal darkness of the eye and prevent internal reflection.* Behind, it is continuous with the pia mater, and in front is prolonged into the ciliary processes and iris, the whole expansion constituting the uveal tract.

The retina varies in thickness from ·4 m.m. at the posterior pole to ·2 m.m. at the anterior part, and morphologically consists of two distinct portions in close contact:—

(*a*) An outside pigmented part adherent to and partly concealing the choroid, representing the non-invaginated part of the "optic-vesicle"; it is composed of a single layer of hexagonal cells (·015 m.m.), loaded with the black "fucsin" crystals.

(*b*) An inside non-pigmented portion, representing the invaginated portion of the optic-vesicle; it consists of the following layers, counting from before backwards:—Internal limiting membrane, nerve-fibre layer (axis cylinders only), layer of ganglion cells, inner molecular layer, inner nuclear layer, outer molecular layer, outer nuclear layer, external limiting membrane, rods and cones.

The rods, which number about 130,000,000, and the cones numbering about 3,360,000, are to be regarded as the special nerve-terminations.

The retina has its own independent system of blood-vessels, *which lie principally beneath the nerve-fibre layer,* and are quite separate from those of the choroid. The arteries, like those of the brain, are "terminal," a fact which explains the blindness which ensues after thrombosis or embolism; also their proclivity to hæmorrhage.

The function of the pigment in the retina and choroid is to absorb the light that has passed through the layer of rods and cones, and so prevent any internal reflection from the white, glistening sclerotic.

The structural peculiarities of the "macular" region will be dealt with later.

OPHTHALMOSCOPIC APPEARANCES.

Be it noted that with the "indirect" metohd the different parts of the fundus are seen reversed and magnified about three times; while with the "direct" method they are seen in their natural position and magnified about fifteen times.

The pattern of the fundus of the two eyes generally corresponds.

The orange-red fundus-reflex or eye-ground, as seen with the ophthalmoscope, is essentially a red reflex from the choroidal blood, somewhat toned down by the pigment in the retina and choroid. Its particular tint may be said to harmonise with the complexion and the colour of the hair; being light or dark, in accordance with the amount of pigment in the skin, there being a distinct correlation between skin-pigment and eye-pigment.

Thus the particular tint of the fundus will vary from the light orange observed in the blonde with the fair skin and hair, to the deep chocolate or slate-colour of the dark-complexioned races. The essential portion of the healthy living retina, the non-pigmentary layer, is, apart from its blood-vessels, *transparent and invisible,* and any loss of this transparency implies disease. The capillaries of the retina are the smallest in the body, and cannot be seen by the ophthalmoscope either individually or collectively. The colouring matter in the pigmentary layer is as a rule sufficiently dense and opaque to conceal from view the subjacent choroidal vessels; it may, however, be scanty, and then they can be seen.

The pigment in the choroid is under ordinary circumstances distributed uniformly throughout the coat; it may happen though that, as seen with the ophthalmoscope, it resembles an irregular mosaic, being massed in definite areas enclosed within the meshes of a pink network formed by the anastomosing choroidal vessels. In subjects in whom the colouring matter generally is scanty, as those with very fair complexions, the pigment areas may be even lighter in tint than the vessels themselves.

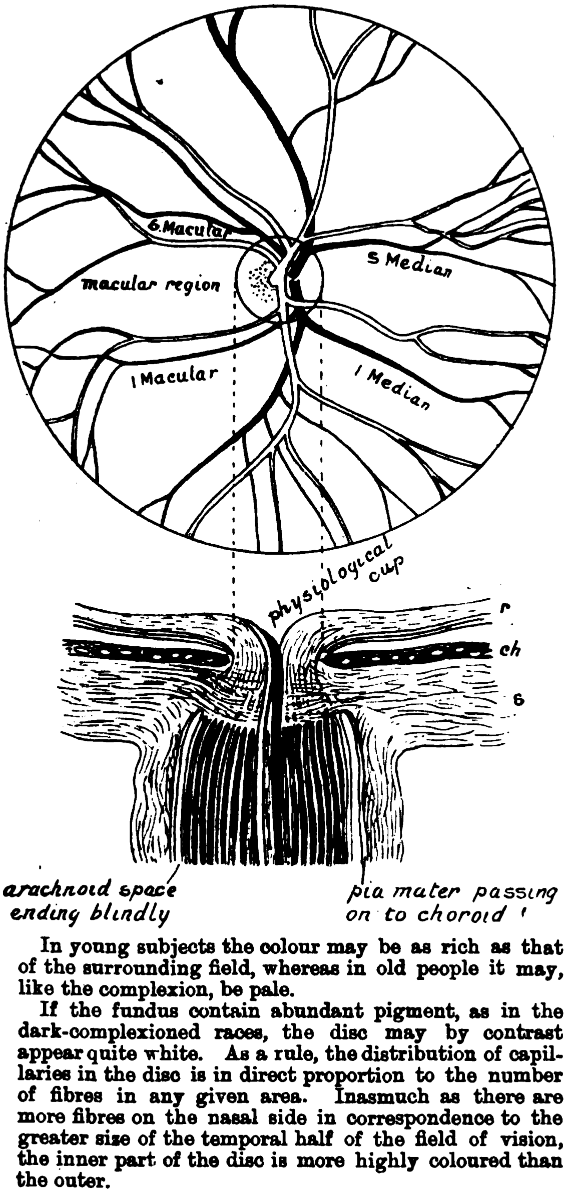
When we speak of the blood-vessels of the fundus we refer *to the columns of blood in them;* the vessel-walls themselves are invisible unless diseased, as is proved by the fact that by pressure on the globe with the finger a vessel may be rendered bloodless when no trace of its walls can be seen.

It is to be understood that the outline of individual capillaries cannot be observed with the ophthalmoscope. No vessel with a diameter of less than 1-700th of an inch is visible, while the average diameter of a capillary is only about 1-3000th of an inch. The upper or lower branch of the central artery of the retina which appears comparatively large as seen with the ophthalmoscope, is in reality only about 1-100th of an inch in diameter. These facts can easily be realised when it is remembered that by the "indirect" method the magnification is about three times the actual, while by the "direct" method it is about fifteen times.

The most conspicuous land-mark in the cup-shaped hollow of the fundus is the intra-ocular termination of the optic nerve, commonly known as the "optic disc" or "nerve head." Paler than the surrounding choroid, it in many cases somewhat roughly suggests a full moon; it is easily recognised by its rounded outline and whitish core, and by the branching vessels which spring from it. The term "papilla" formerly applied is a misnomer, as under normal conditions it does not project beyond the level of the plane of that zone of the retina immediately around it. *Its tint is always redder in the young than the old,* and it is an ophthalmic maxim that its shade of colour may be as varied as that of the cheek.

The usual shape of the disc is circular or oval, and although much magnified by the ophthalmoscope, its actual diameter is about 1·5 m.m., and its position some 15° to the nasal side of the posterior pole, so that in order to bring it into view the cornea must be turned a little inwards towards the nose.

The border of the disc is sharply defined, except in "optic neuritis," and certain cases of astigmatism; and in colour it exhibits an outer pink zone, due to the presence of numerous capillaries, surrounding a whitish central core.



In young subjects the colour may be as rich as that of the surrounding field, whereas in old people it may, like the complexion, be pale.

If the fundus contain abundant pigment, as in the dark-complexioned races, the disc may by contrast appear quite white. As a rule, the distribution of capillaries in the disc is in direct proportion to the number of fibres in any given area. Inasmuch as there are more fibres on the nasal side in correspondence to the greater size of the temporal half of the field of vision, the inner part of the disc is more highly coloured than the outer.

Scleral Ring.—Sometimes, and more especially in old people, the disc is seen to be encircled by a pale ring, complete or incomplete, and usually not of uniform thickness, being wider as a rule below. It is generally known as the "scleral ring," but this term is a misnomer as it is in reality due to a band of connective tissue which surrounds the head of the optic nerve in the same way as a piece of cotton or string encircles the stalks of a bunch of flowers.

Choroidal Ring.—External to the scleral ring, either in conjunction with it or not, may sometimes be noticed another ring, the "choroidal ring," black in colour, and caused by the heaping up of pigment along the annular margin of the choroidal aperture. It may form either a complete circle, but is usually defective in places; the pigment is usually massed mostly along the outer side, and then may take the shape of a black crescent, liable to be mistaken by the inexperienced for a pathological change. Both these rings are often absent.

In consequence of the floor of the cup being sunk below the level of the surrounding fundus the observer, on moving his head from side to side, will notice a parallactic displacement of the parts.

The manner of formation of the physiological cup is as follows:—The lamina cribrosa, or spot at which the optic nerve fibres pierce the globe, consists only of the inner third of the thickness of sclerotic, the outer two-thirds peeling off and blending with the outer sheath of the nerve. Just before entering the lamina cribrosa the 500,000 medullary sheaths of axis cylinders of the optic nerve abruptly cease, just as the sleeve ends at the wrist, and in bundles of varying sizes pass through the sieve like holes in the lamina cribrosa.

In the pale central part of disc the floor is generally sunken below the surrounding level, giving rise to a funnel-shaped depression, the "physiological cup." The size, shape, and depth of this cup all vary within somewhat wide limits; sometimes it is so small as to be barely recognised, while in extreme cases it may be so large that by the inexperienced its boundary may be mistaken for the actual border of disc. It never occupies, however, the whole of the area of the nerve-head, for by careful inspection it can always be seen to be surrounded by a distinct pink belt of disc margin. (*a*)

After having emerged through these holes, and prior to reaching the plane of the retina, the fibres open out from one another like the petals of a flower, forming in this way a funnel-shaped hollow, the physiological cup.

Although of diverse size, shape and depth in different individuals, as a rule the cup on the temporal side is shallow and shelves gradually down, whereas on the nasal side it is steep, sinking down abruptly.

In many cases, owing to the way the nerve-fibres separate out, the lamina cribrosa is exposed to view: under these circumstances the cavity of the physiological cup appears not of one uniform colour but "mottled," dark-grey spots lying imbedded in a steel-coloured ground. The dark-grey spots are due to the bundles of naked axis cylinders being seen as they pierce the lamina cribrosa, and as they reflect less light than the fibrous tissue of the lamina cribrosa itself, present a darker colour.

The area of the lamina cribrosa, consisting as it does of but the inner third of thickness of sclerotic, is the weakest part of the eye-capsule, and accordingly, in conditions of increased tension is the first part to yield (glaucomatous cup) moreover, the holes in the lamina cribrosa being rigid, the axis cylinder of the optic nerve are very liable to become strangulated in optic neuritis, and to pass on to atrophy.

MYOPIC CRESCENT.

During the elongation of the posterior segment of the globe which takes place in myopia, the annular margin of the choroidal aperture on the side facing the macula undergoes atrophy, exposing a corresponding area of the white sclerotic. Under these circumstances a white crescent, with its convex margin either sharply cut or ill-defined, often edged with black, is seen on the immediate outer side of disc; this is known as the "myopic crescent." In rare cases a somewhat similar appearance may be observed in emmetropia and hypermetropia.

(*a*) In glaucoma the cupping involves the entire optic disc, and the edges are undermined, which they never are in physiological cupping.

In the higher grades of myopia the choroidal atrophy may be so extensive that the entire nerve-head is encircled by a zone of exposed sclerotic, and sometimes the white patch may extend irregularly for a considerable distance. When it forms a ring care must be taken not to mistake it for the boundary of the disc.

Peculiarities in Development.

The congenital crescent is a whitish crescent with convexity downwards. This is a somewhat uncommon condition; its distinguishing feature is that it occupies a situation immediately *beneath* the disc either directly or a little sideways and beneath. It is generally thought to be due either to exposure of the sclerotic, the result of the fœtal cleft failing to close completely up to margin of disc, or else to the fact of the connective tissue of the lamina cribrosa being especially thick and dense at the lower part of disc.

Coloboma of choroid results from the non-closure of fœtal cleft causing the exposure of corresponding area of the sclerotic. It occupies a situation in the lower part of the fundus, being usually wedge-shaped, with base below and apex at some distance from the disc, and sides pigmented. The retinal vessels usually course over the patch, but the rest of the tissue of the retina is either incompletely developed or entirely absent. The floor of the gap is usually sunk, as the sclerotic over the area is generally thin, and in rare cases may yield to the intraocular tension to such an extent that an actual cyst forms which may exceed the eye in size. It is usually associated with coloboma of the iris.

Coloboma of Disc.—This may exist by itself or in conjunction with coloboma of the choroid. It is due to imperfect closure of the fœtal cleft at the lower part of the disc. The disc below appears enlarged, with a depressed floor, the vessels dipping down into it.

Vessels.—With the exception of those in the disc, the retinal arteries, like those in the brain, are "terminal." Although their general distribution is more or less the same in nearly all cases, their exact course is subject to variation. As a rule the arrangement in the two eyes corresponds.

Usually, the central artery issues from the disc as a single trunk and somewhat ex-centrally, then divides into a superior and inferior branch which runs respectively upwards and downwards in a more or less vertical direction, the upper giving off a superior temporal and superior nasal, and the lower inferior temporal and inferior nasal. While the main branches are yet on the disc, each gives off a superior and inferior macular and superior and inferior median. The macular arteries skirt the yellow spot, taking a sweep over and beneath it. No visible vessel can be traced into the macula.

Cilio-retinal Vessels.—Occasionally independent cilio-retinal vessels, derived from the posterior ciliary, emerge from the temporal side of disc and pass outwards towards the macula; the existence of these vessels explains the fact that occasionally in embolism of the central artery the portion of the retina supplied by them retains its vitality. Subsequently, the vessels subdivide by a successive series of bifurcations, the general arrangement of the veins corresponds to that of the arteries. Both sets of vessels lie just beneath the nerve-fibre layer, a fact that explains the flame-shaped character of the typical retinal hæmorrhage. All the larger vessels are surrounded by perivascular lymphatics, which, like the vessel walls, are invisible. No capillaries have been traced by the aid of the microscope to the rod and cone layer. The fovea centralis has likewise been proved to be non-vascular.

In the small eye of hypermetropia the vessels may appear tortuous and sinuous, as though they were developed for the larger emmetropic eye. For a similar reason they often run a comparatively straight course in the bigger eye of myopia.

Occasionally there may be a persistent hyaloid-artery, consisting of a single solid thread short or long, attached to the central artery.

As a rule, the main vein lies completely buried in the disc, the two constituent branches piercing it separately.

There is no constancy in the arrangement of the companion veins; two veins may run with one artery or one vein with two arteries.

If a single vein accompany a single artery the latter is generally about two-thirds the size of the former, the reason being that the artery is more distended with blood and so presents a cylindrical, while the less distended and more flaccid vein presents a flat tube. Broadly speaking, the diameters of the retinal veins are in inverse ratio to their number. Comparison of retinal arteries with retinal veins:—Arteries: Lighter in colour, smaller in size, straighter in course, cylindrical in shape, branches do not anastomose. If viewed on a plane perpendicular to observer's visual axis, show a well-marked median light stripe. Veins: Darker in colour, usually larger, less straight in course, flattened in shape, median light stripe much less defined. Pulsation in the retinal vessels.

Venous pulsation is physiological in over 70 per cent. of eyes. It occurs as a "throbbing" to be noticed more particularly in the main trunks as they lie on the disc.

Arterial pulsation can be produced artificially by pressure on the globe by the finger, and in rare instances may be physiological. It is occasionally found in the severer forms of anæmia, and is always present in glaucoma when intraocular tension is raised. It is of frequent occurrence in aortic regurgitation, being more marked the greater the hypertrophy of the left ventricle. By careful focussing, the tube can be seen to broaden and lengthen out, the former peculiarity being especially noticeable if attention be directed to a point on the vessel just before its bifurcation, and the latter if attention be directed to any spot on the artery at which there is marked curving. The pulse-wave can generally be traced a considerable distance along the course of the vessel, like the "locomotor pulse" as seen on a surface artery, and so characteristic of "aortic regurgitation"; in this respect it differs from the pulse seen in glaucoma, which is generally confined to the disc and its immediate neighbourhood.

"Macular" or "Yellow-spot" region is the area of maximum retinal light-sensitiveness, and closely corresponds in situation with the posterior extremity of the optic axis, being located about two disc-diameters from the outer side of the nerve-head (3 to 4 m.m. external, and 1 m m. below, centre of optic-disc). The term "yellow-spot" refers to a post-mortem change, and never presents this colour in an ophthalmoscopic examination during life. Circular or elliptical in contour, its average diameter is about 2 m.m., and its area has been estimated at about 2¼ square m.m. (2·356). It is brought into view when the patient is directed to look straight forward, and its ophthalmoscopic appearance varies within wide limits both in different persons, and under variations of illumination in the same person.

The colour is usually deeper than that of the surrounding parts, but it has no well-defined boundary, and to the beginner is the least conspicuous part of the fundus, by him being more often recognised by its negative than by its positive characters.

The retinal vessels sweep round, and no visible one can be seen to enter it.

Histology.—The boundary of the macula is slightly raised on account of the existence here of seven or eight additional ganglion-cell layers. From the raised rim the layers gradually fine down to the centre, a spot generally known as the "fovea centralis," which is the thinnest part of the retina, consisting of but two layers, the "cones" and "outer-nuclear." In the middle of the fovea centralis there may be a minute dimple. The macula as a whole, owing to its raised rim and depressed floor, may be likened to a very tiny crater.

The crater-like depression of the macula cannot be seen with the ophthalmoscope, but owing to the extreme thinning of the retina here, and consequent exposure of the subjacent pigment, it sometimes exhibits a red-brown spot, an appearance more usually to be observed in subjects with dark complexions, due to the subjacent pigment being especially exposed.

"Crick," or Gunn's Dots.—This is the term applied to a rare physiological condition in which minute pale

or yellow coloured dots are to be seen in the macula region, and sometimes suggesting very tiny seeds. They may be very conspicuous, especially if the illumination be feeble, while, on the other hand, the light may require to fall upon them in a particular direction in order to render them visible.

Reflexes.—Certain phenomena, known as "reflexes," may sometimes be observed in the yellow-spot region, and in relation to the larger retinal vessels. As a rule they are only to be met with in children.

They generally have a peculiar satiny shimmer, and may be of three kinds: *(a)* Macular reflex; *(b)* foveal reflex; *(c)* vascular reflex.

(a) The macular reflex, when present, is generally to be seen in the form of a "dancing halo" or luminous ring around the fovea, and shifting its position on moving the mirror. It is an inverted image of the ophthalmoscopic mirror reflected from the raised and convex line of the macula.

(*b*) The foveal reflex when found usually takes the form of either a bright (*a*) crescent or (*b*) sparkle. If the former (*a*), it may be noticed to move about in such a way that its concave side presents itself towards that part of the retina to which the eye of the observer is directed. If the observer can concentrate his gaze towards the very bottom of the pit the crescent may sometimes be noticed to change into a tiny ring with a central sparkle. The crescent is in reality an image of an arc of the "sight-hole" of the ophthalmoscope, the bottom of the foveal pit behaving as a concave mirror, while the "ring" is an image of the circular rim of the reflector, in the former case the annular opening being excentric to the pit and in the latter centric to it. (*b*) The sparkle, also a reflection from the concave macula, suggests the appearance of light radiating from a bull's-eye lantern, and is generally known as the policeman's lantern reflex.

(*c*) Vascular reflexes are to be noticed as a rule only in children, rarely in adults. They take the form of dancing reflexes in relation to the larger branches of the retinal vessels, in which connection they appear as bright, lustrous, shifting lines or bands with a characteristic satiny shimmer; sometimes they assume the shape of forked lightning. They are no doubt images of those parts of the ophthalmoscopic mirror from which they receive the light.

With advancing life all these reflexes disappear or else become very faint. An important point in connection with them is that they all shift with movements of the mirror.

The pathological changes which may occur in the macular region are those more especially in connection with chronic Bright's disease, central choroiditis, and senile conditions.

As previously stated, the characteristic orange-red fundus reflex is a composite effect, the result of the mingling of the red of the blood in the choroid with the eye pigments, the colour being darkest in the neighbourhood of the posterior pole and becoming lighter towards the periphery in accordance with the distribution of the pigment, which is most abundant in the region of the macula thinning out towards the ora serrata. Under ordinary circumstances the vessels in the choroid are not visible except at the periphery.

Sometimes, however, and within physiological limits, the individual vessels of this tunic may be observed with the ophthalmoscope, especially under the two following conditions:—

(a) In a very light-complexioned subject, the choroidal and retinal pigments not being abundant, the choroidal vessels may be noticed in the form of an anastomosing pale red network; while *(b)* in a very dark-complexioned subject in whom the eye pigments are abundant, the fundus may have a tessellated appearance, being mapped out into an irregular mosaic of dull-coloured patches embedded in the network of red anastomosing choroidal vessels.

We must assume in both these cases first a relative absence of the retinal pigment which when fully developed, conceals the outlines of the choroidal vessels, and secondly, a special concentration of the choroidal pigment in the intervascular spaces, and a comparative absence of it over the vessels themselves.

The vessels of the choroid can never be mistaken for those of the retina if the following facts are borne in mind: they freely anastomose, forming a net; they have no light stripe; in outline they are not so clearly marked and are more pink in colour.

With careful focussing by the direct method, especially in the neighbourhood of the macula, a fine granular "stippling," or appearance suggestive of very minute grains of sand may occasionally be observed.

This arises from the hexagonal cells containing the black fucsin crystals of the pigmental layer of the retina being brought into view. Each cell measures about ·015 m.m. in diameter, which when multiplied by 15 (the magnification of the direct method) gives an apparent size of ·225 m.m.

By the inexperienced observer these granules may be mistaken for a pathological state.

As before stated the tissues of the non-pigmentary portion of the normal retina being, apart from its arteries and veins, transparent, it is during life invisible by means of the ophthalmoscope, and with the notable exception of "opaque nerve fibres," any opacity present therein indicates a pathological change.

Occasionally, however, and as a rule only when the choroidal pigment is abundant, the actual retina can be seen in the form of a fine, softly-tinted, pearly-grey film, or very delicate gauze, and although a very exceptional condition among Europeans, in the black-complexioned races the delicate axis-cylinders of the nerve-fibre layer can usually be seen radiating into the general retinal expansion.

Opaque Nerve-fibres.—Though the normal, living, non-pigmentary portion of the retina is transparent, the condition known as "opaque nerve-fibres" may, as a rare congenital peculiarity, be found in one or both eyes. As before explained, the medullary sheaths abruptly cease just beneath the lamina cribrosa, leaving the axis-cylinders naked, but in this case they resume them for some distance into the retina, giving rise to snow-white, striated, feathery-edged patches which conceal the fundus-pigment and in places bury the vessels.

Although generally joined to the disc, they may occur in the form of separate "islands." They must not be mistaken for spots of choroidal atrophy, which are as a rule clean-cut with an enveloping ring of dark pigment, and have the retinal vessels coursing over them; nor for the white patches of albuminuric retinitis, being clearly distinguished from such by their flame-shaped, feathery, fringed, fibrillar, or hair-like edge. In rare cases the medullary sheaths extend on to the disc, concealing a portion of it. The retina is blind over these areas. In the rabbit the condition is a normal one.

NOTES ON A CASE OF

OSTEOID CHONDRO-SARCOMA OF THE FEMUR,

TREATED BY DISARTICULATION AT THE HIP-JOINT; WITH EXHIBITION OF SPECIMEN, PHOTOGRAPHS, AND MICROSCOPIC SPECIMENS. (*a*)

By C. YELVERTON PEARSON, M.D., F.R.C.S.,
Professor of Surgery, Queen's College, Cork.

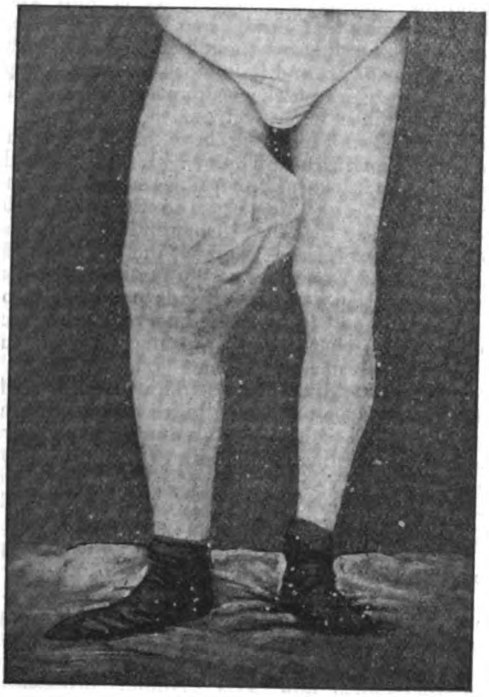
C. C., æt. 58, farmer, fell from a ladder on his heels nearly eight years ago; heard something give way at the knee, and was unable to stand for three weeks. After this he got about his business as usual. Two years after, he got another fall from a ditch. This was followed by pain above the right knee; and a tumour, at first about the size of a marble, was noticed during the following twelve months. Four years ago, *i.e.*, two years after the second fall, he had to get his trousers enlarged in

---

(*a*) Read before the Pathological Section of the Royal Academy of Medicine in Ireland, May 2nd, 1902.

consequence of the swelling. Two years after this he was admitted to the North Infirmary under the late Dr. O'Sullivan, when amputation was advised. This he declined at the time for family reasons, and returned home. He was re-admitted August 16th, 1901, and prepared to submit to amputation, the tumour having steadily increased and the limb having become very painful.

Present Condition.—Has a large irregular swelling, occupying the lower two-thirds of the right thigh, some portions of which feel very dense. Circumference of tumour at widest part = 13 ins.; of limb above = 21 ins.; of limb below = 17 ins. There is marked mapping of the veins, which are much enlarged, on the inner and anterior aspect. A rose-coloured rash of a lichenous character, consisting of groups of papules with intervening hyperæmic skin, is present on the lower portion of the swelling at the inner side of the knee-joint. The leg below is considerably swollen and œdematous. The appearances are well illustrated in the accompanying photograph. The glands in the groin are considerably enlarged and of stony hardness. The patient's health was good and no evidence of other disease was present. Amputation at the hip-joint was performed on August 22nd.



Operation.—A vertical incision, 4 ins. in length, commencing a little below Poupart's ligament, was made over the femoral vessels. The common femoral artery and vein were ligatured, then the superficial and profunda arteries and veins. The vessels were then divided between the ligatures. The enlarged lymphatic glands were now dissected out from the groin. The amputation was completed by a rachet-shaped incision. The various vessels were secured with compression forceps as divided, no tourniquet or digital compression being employed. The progress of the case was most satisfactory for the first three or four days, but subsequently the dressings became contaminated with urinary and fæcal discharge, and suppurative inflammation took place, in consequence of which the patient made a slow, though very satisfactory recovery.

Pathological Report, by Dr. A. E. Moore.—The tumour consists chiefly of cartilage, but contains sarcomatous elements and some extensive ossific centres. Microscopic examination shows that some parts are composed exclusively of large cells; in other parts the process of ossification in cartilage is well displayed; while some sections leave no doubt of the sarcomatous nature of the growth. Judging both from the appearance and the history there is no doubt that the tumour originated as a periosteal chondroma, and subsequently developed malignant characters. Examination of the glands removed from the vicinity of the common femoral vessels showed that they contained calcareous deposit and large cartilage cells, the nuclei of which exhibited the phenomena of karyokinesis, and leave no doubt as to the glands being the seat of secondary deposit.

Remarks.—The chief points of interest in this case to my mind are:—

1. The traumatic origin, which seems so frequent in the case of sarcomatous growths, and especially of those affecting bone.
2. The infection through the lymphatic system.
3. The long periods which elapsed from the origin of the tumour before it took on a malignant character.
4. The subsequent history of the case, which shows that the infection had travelled beyond the region of operative interference, as a few weeks ago the patient was re-admitted to the infirmary suffering from severe pain in the abdomen, which on examination was found to be due to the presence of a large tumour in the epigastrium, which had a well-marked impulse transmitted from the aorta, and is, I have no doubt, the result of secondary implication of some of the lumbar lymphatic glands.
5. The method of amputation adopted which provided for ligature of the main vessels and extirpation of the glands previous to disarticulation, and which dispensed with the use of tourniquet or other special methods of controlling hæmorrhage in what is justly regarded as the most formidable of amputations.

FALLACIES IN THE COPPER REDUCTION TEST

FOR

SUGAR IN THE URINE (*a*).

By FRANCIS D. BOYD, C.M.G, M.D., L.R.C.P.

Physician to the Deaconess Hospital, Assistant Physician to the Edinburgh Royal Infirmary.

IT not infrequently happens that cases come before medical men who have much to do with insurance work in which the occurrence of reducing substances in the urine, other than glucose, gives rise to considerable difficulty. One is quite familiar with the case of the stout, elderly patient, of a nervous temperament, who braces himself up to face the ordeal of medical examination by taking a glass or two of champagne, and then presents symptoms of transitory or alimentary glycosuria. Apart from such persons, however, it is common to meet with urines free from sugar which, nevertheless, partially reduce Fehling's solution, and the circumstances under which such a reduction takes place demand the attention of the practical physician. The observations were made in the following manner: 2 cc. of Fehling were taken and tested with solutions of reducing agents of known strength, the time at which reduction began and that at which it was completed, and the quantities of the reagents required being noted in each case. The amount of diabetic urine needed completely to

---

(*a*) Paper read before the Edinburgh Medico-Chirurgical Society July 2nd, 1902.

reduce this quantity of Fehling ought not to exceed 1·5 cc. A subsequent microscopic examination of the deposit was made in each case. The following are the principal fallacies met with in testing for sugar :—

1. Glycuronic compounds. These occur in the urine of some healthy persons, as well as after taking such drugs as camphor, terebene, &c., belonging to the aromatic series, in infectious diseases, and in sepsis, typhoid, tonsillitis, &c. These bodies are generally regarded as protective in their nature and are the results of the conversion of toxic aromatic substances into innocuous compounds. If present in abundance they reduce Fehling, and may be detected by the phenyl-hydrazin bromide method, which yields a microscopically recognisable deposit of crystals, by the fact that they reduce copper and bismuth in alkaline media, by a negative result on applying the fermentation test, and by the addition of hydrochloric acid and orcin or phloroglucin, with which they give a red colour, turning a reddish blue, and then throwing down a blue precipitate giving a green solution in alcohol. Finally, they may be detected spectroscopically by their characteristic absorption bands.

2. Creatinin is given by the text-books as a possible fallacy in carrying out the test with Fehling. On boiling a urine containing creatinin with that reagent a green discolouration takes place. Creatinin is derived from the food substances, and completely to reduce 2 cc. of Fehling ·07 gramme is required. This is much more than is ever present in 1·5 cc. of urine, so that practically this fallacy may be excluded. The test for creatinin is the usual nitro-prusside reaction.

3. Uric acid is another text-book fallacy. Here again a very larger quantity (·03 gramme) is required to reduce 2 cc. of Fehling completely than is ever present in the urine. Unless there is a very great excess of uric acid present, this, therefore, is a fallacy which need not trouble us at all.

4. Alkaptonuria is a not very uncommon condition in intestinal putrefaction, constipation, &c. Here exposure to the air turns the urine darker, and the addition of an alkali turns it darker still. The Fehling's solution gives a dark brown solution turning black, and yielding a black precipitate, which further reduces copper on boiling. The presence of pyrocatechin or hydroquinone in the urine gives a similar reaction. Here the change of colour which the urine undergoes is characteristic, and should prevent alkaptonuria being mistaken for glycosuria.

5. As regards the identification of the different osazones — phenyl-glucosazone, phenyl-lactosazone, phenyl-pentosazone, &c.—chemists recommend the estimation of their melting point as the only trustworthy method, but this is not clinically available. It will be found that the crystals of these bodies have a different microscopical appearance, and with a little practice they can be distinguished from one another. The matter may be summarised as follows :—(1) Creatinin and uric acid can be practically neglected as a source of error. (2) In alkaptonuria the darkening of the colour of the urine is characteristic. (3) No error is likely to arise in carrying out the Fehling test if the observations are made *below the boiling point.* The Fehling should be boiled in one test tube, the urine in another, and the two allowed to cool slightly before mixing. By this method only sugar will reduce Fehling. In cases where further evidence is required the phenyl-hydrazin test for sugar, the phenyl-hydrazin bromide test for the glycuronic compounds, and the fermentation test, are conclusive.

It has been decided to invite the members of the British Medical Association to hold their annual meeting in 1903 at Swansea.

PERIPHERAL THEORY OF NERVE REGENERATION WITH SPECIAL REFERENCE TO PERIPHERAL NEURITIS (*a*).

By ROBERT A. FLEMING, M.A., M.D., F.R.C.P. Ed.,
Assistant Physician to the Edinburgh Royal Infirmary.

There are two theories of nerve regeneration, the central and the peripheral. According to the *central theory*, regeneration of a divided nerve takes place solely by the penetration of the axis cylinders, or of outgrowths resulting from the sub-division of the axis cylinders, from the proximal end of the nerve into the distal part. The facts which weigh against this theory are the results of secondary suture, that is, suture of nerves which have been divided for months or longer. As is well known, such suture may be followed by a return of sensation in the area supplied by the affected nerve within a few hours or days, and it is most difficult to explain this rapid recovery on the assumption that regeneration takes place entirely from the centre to the periphery. Two hypotheses have, however, been put forward to explain the difficulty :—1. That not all the axis cylinders in the peripheral segment of the nerve degenerate, although they cease to stain. From this it follows naturally that the sensory end organs must be supposed to exercise a trophic function, and Marie has carried the reasoning a step farther, and asserts that degeneration actually extends upwards into the proximal portion of the divided nerve. 2. The second explanation is that there is an anastomosis among the peripheral nerves, whence axis cylinders are developed in the divided one, and are ready to take on function as soon as union takes place. From the central theory it results that an amputation neuroma must be regarded as a splitting or multiplication of pre-existing axis cylinder processes, and that in grafting the graft is penetrated from its proximal end only. The *peripheral theory* may be formally stated in the shape of five propositions :—1. The peripheral part of the divided nerve degenerates in its entirety. 2. The phagocytes removing the myelin sheathes are first the leucocytes, then the connective tissue corpuscles, and then the neurilemma cells. 3. The neurilemma cells then regenerate new axis cylinder processes by assuming a neuroblastic action. 4. This regeneration is only, however, complete if the ends of the divided nerve are ultimately united. 5. The amputation neuroma is due to a regeneration of fibres in the proximal end, similar to what takes place in the distal portion, and a graft is penetrated by axis cylinders from both ends, not one only. For the study of these changes Stroebe's stain is invaluable, and affords convincing evidence of the truth of the peripheral theory. Nevertheless, the central theory cannot be entirely discarded. If we are to regard the amputation neuroma as of neuroblastic origin we seem almost to endow the neurilemma cells with the property of malignancy, although it is true that in their proliferation they do not infiltrate the skin and surrounding tissues.

In peripheral neuritis a similar peripheral regeneration of nerve fibres takes place, as is shown by four cases examined post-mortem. All were typical cases of alcoholic neuritis, and showed the usual paræsthesiæ, paralysis, loss of knee jerks, muscular tenderness, &c. In peripheral neuritis the toxin affects the whole lower neuron, whose trophic centre is a nerve cell, either in the anterior horn of the grey matter or (in the case of centripetal fibres) in the ganglion of

---

(*a*) Paper read before the Edinburgh Medico-Chirurgical Society, July 2nd, 1902.

the posterior root. We have therefore to consider the changes first in the cells, and secondly in the axis cylinder processes. Affected nerve cells show chromatolysis, the nuclei become eccentric in position, and are finally almost extruded from the cell, while the Nissl's bodies cease to take on the stain. In the peripheral nerves there are first vascular changes, consisting in thickening of the inner and middle coats of the arteries so that the lumen becomes almost impervious; secondly, an enormous amount of exudation which probably gives rise to the clinical sign of hyperæsthesia; third, the axis cylinders degenerate more or less, the finer fibres suffering to the greatest extent. In the first and second of the cases examined, but not in the third, regeneration had taken place by means of neurilemma cells in the peripheral nerves, while in the fourth case there were signs of regeneration in the phrenic nerves only, yet the patient died with paralysis of the diaphragm. In connection with Dr. Fleming's paper a large collection of microscopic preparations, drawings, and lantern slides were shown in illustration of the various points referred to.

THE DIFFERENTIAL DIAGNOSIS OF PLEURITIC EFFUSIONS.

By Dr. ALEX. VON KORANYI,
Professor at the Faculty of Medicine of Budapest.

It is well known to clinicians that many cases of pleuritic effusion are difficult, if not impossible, to delimit by percussion owing to one or more of the solid organs, such as the liver, lying in the immediate neighbourhood of the effused liquid. These cases, rare though they be, are sufficient to prove the existence of certain defects in our means of clinical investigation. The importance of Traube's space in the diagnosis of left-sided effusion is also a factor in the diagnosis of all such cases, one, too, that should not be overlooked in the delimitation of the chest. This is a space which is often filled by increase in size of the liver, the heart, or the spleen, and these conditions require to be differentiated from pleuritic effusion. The space is in the lower part of the thorax lying between the liver and spleen. This, the so-called Traube space, is often the most difficult to percuss owing to the frequency of its being filled with fluid, while above it may be found the consolidated lung, fluids always gravitating to the lowest level. In this case the crescentic outline of the lung will still be observed whether the dulness be present or not. The same difficulty prevails posteriorly in defining the limits of the lung and spinal column. It is with this object in view, and to elucidate the utility of transsonant percussion, that the author has approached the subject.

If the stethoscope be placed over a solid organ of the body at a point where it approaches the parietes, and the part percussed at the same time, a peculiar sound of a shrill ringing character will be heard. This sound continues as long as the percussion is within the parietal contact-limits of the auscultated organ, but ceases immediately the limit is passed. By this means the surface contact of a parietal organ can be accurately delineated on the surface of the body. The author has marked out the boundaries in many obscure cases by this topographical percussion, which could not have otherwise been accomplished. The author uses a simple binaural stethoscope with two indiarubber tubes fitted with olive-shaped vulcanite ends for the ears. The point of the left index finger is pressed well down into the surface of the body and then struck with the firmly extended finger of the right hand. This form of percussion is a slight modification of Reichmann's, who employed a rod to press into the surface, which he struck with the finger in percussing. Either method may be employed in this form of auscultation, and the results obtained will be in proportion to the operator's experience of the particular method, as the principle is the same, though reduced to its simplest form in the striking of the finger.

The method adopted by the author is to press the point of the left index finger well into the thorax, and then strike it with a finger of the right hand; either method gives a similar tone by the stethoscope. Long and careful observation is absolutely necessary to prevent mistakes. One point might be noted for the benefit of those who have not practised this form of auscultation, viz., that the distance between the finger and the stethoscope must not be too great, or the sound may be so altered as to lead to error; it is therefore necessary that the finger should slowly and methodically follow the stethoscope in percussing the organ. Again, the ribs are good conductors of sound, and may lead to error if the finger be not well pressed down between them, more particularly in the neighbourhood of the sternum. In the event of one's not being able to get between the ribs, an assistant may be directed to place his hands on the chest on either side of the point which is under examination; for instance, one on the sternum and the other on the lateral wall of the thorax. By this device the author has been able to percuss the most complicated cases with excellent results.

This form of auscultatory percussion enables one to analyse the dulness of a number of organs lying in very close proximity to each other, which can be done with perfect accuracy and ease, when the heart, liver, and stomach are clearly defined.

This method of diagnosis is particularly valuable in left-sided pleuritic effusion. If the stethoscope be placed on the outside of the cardiac area it will be found to have extended far into the effusion if followed to its outer border. In percussing the exudation itself it must be borne in mind that the upper part of the dulness does not accurately define the limit of the effusion, as more accuracy will be required to define the line of demarcation between the compressed lung and the fluid. If the thorax be percussed behind, it will be difficult to limit the effusion externally, as the lung will gradually sink; but if percussed towards the spinal column it will be found to go across the medial line, towards the right or healthy side.

The lower margin of the fluid is another important feature in the diagnosis, which practically should extend from the twelfth rib posteriorly along the margin of the thorax to the front, but in practice it will be found to be far below the marginal vault of the thorax, as the exudation by its own weight tends to push the diaphragm down, and thus distend the pleural sac in that direction. On the other hand, the empty lung will be found, not in the complementary space made by this depression of fluid, but highly placed in the posterior part of the thorax about on a level with the ninth rib in the scapular region. It will be seen that the defining of an effusion is a long and tedious process, and entails what in many cases is unnecessary labour; but questions do sometimes arise that tax our ingenuity to the utmost to delimitate effusions from some other morbid change that may lead us astray in operating—for instance, if it be doubtful whether the case is pleural effusion or pneumonia, or whether there is effusion with pneumonia. This can easily be differentiated by placing the stethoscope within the scapular line and slowly percussing outwardly. If a pleural effusion exist the dulness will follow the costal curve, but if it be pneumonia without effusion the alteration in sound will be two inches higher than the curve. By the same process of examination both sides may be high and reveal double pneumonia, while an effusion in both sides would be two inches lower than the normal.

The author urges that no one should be without this knowledge in the diagnosis of disease, which can only be made practical by long experience and careful observation. Its value is not confined to the delimitation of Traube's space, as he has already shown, but may be extended to many obscure cases constantly presenting themselves to the clinician.

In conclusion, it should be noted that the thick muscular masses on both sides of the spinal column are good conductors of sound, and may lead to an erroneous conclusion when percussed by the resonant method; but if the scapular line be taken as a guide, there is less risk of error.

Clinical Records.

CASE OF INTESTINAL FISTULA, PROBABLY JEJUNAL. (a)

Under the care of **Hy. M. Church, M.D., F.R.C.P.Ed.**

The patient was a lady, æt. 46, who had been operated upon for acute obstruction of the bowels, with stercoraceous vomiting, in 1884. Finding that he could not relieve the obstruction otherwise, the operator had made an artificial anus, and the patient had lived for eight years, during the last of which she was under Dr. Church's care. He quoted Mr. Golding Bird's case of jejunostomy for malignant stricture of the pylorus, in which an attempt was made to prolong life by artificial feeding through an intestinal fistula. In this case no food whatever was given by the mouth, and no regurgitation ever took place from the bowel, but as the patient lived only for nine days after the operation no definite information was yielded by the case. In Dr. Church's patient the chief distress was caused by the extremely irritating digestive effect of the pancreatic juice on the skin. The fistula was of such a size as just to admit the tip of the little finger, and was situated about an inch above the umbilicus in the middle line. It was constantly surrounded by a zone of excoriated and inflamed skin, over which the watery odourless pancreatic secretion trickled. Morphia was found of the greatest service in treating the case—it was food to the patient, and dried up the secretion of pancreatic juice in a wonderful manner. Its sole disadvantage was its anti-sialogogue action, which kept the patient constantly thirsty. Caffeine-citrate was given in 5 gr. doses for headache, but immediately increased the flow of saliva and of the pancreatic secretion from the fistula. In larger doses it gave direct evidence of being a gastro-intestinal irritant. In small doses rhubarb checked the discharge completely for three or four hours, and then escaped by the fistula. Castor-oil proved an active and non-irritating purgative, acting in from one and a half to two hours. Alcohol invariably increased the flow from the bowel, and had therefore to be denied to the patient. Many years of experience had told the patient that vegetable diet always disagreed, and that a purely proteid diet was best tolerated. The painful condition of the skin was best relieved by the application of tannic acid and vaseline. Dr. Church also referred to Dr. MacFadyean's observations on his case of fistula at the lower end of the ileum.

An inquest was recently held on a woman, æt. 36, who died from pleuro-pneumonia, associated with phosphorus-necrosis of the jaw. She had worked at Bryant and May's for seventeen years.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD ON WEDNESDAY, JULY 2ND, 1902.

Peter Horrocks, M.D., President, in the Chair.

A FATAL CASE OF ECLAMPSIA.

Dr. **Bell** read a short paper on a fatal case of eclampsia, in which an autopsy was made, and he showed the liver and microscopic sections of the liver and kidney. The patient, a single woman, æt. 21, was brought into St. Thomas's Hospital in a state of coma. Prodromata of eclampsia in the form of headaches, &c., came on in the fifth month. In the eighth month coma came on, and she was then taken into hospital. Only a trace of albumin was found in the urine. Delivery was effected by dilating the cervix with Champetier de Ribes' bag, and extracting the child with forceps. There was not much hæmorrhage, but the patient became faint; after a copious venous transfusion she rallied. On the next day she developed jaundice and a temperature of 102° F. Two days later the pulse suddenly failed, and she died. At the post mortem the liver showed two large infarcts, and microscopically it presented the characters of the early stages of acute yellow atrophy, there being a great deal of fatty deposit both in the liver and in the kidneys. Some blood serum was injected into two guinea-pigs, which died within twenty-four hours. As a control experiment the blood of two uræmic cases which happened to be in the hospital at the same time was injected into two other guinea-pigs, without any result. Pathologically the case was one of acute yellow atrophy, though clinically it was one of eclampsia; at the same time, some of the microscopical characters were not entirely typical of acute yellow atrophy. Thus there was less infiltration round the portal vein than was commonly met with in this condition; and there was more fat than usual. It was probable that they would have to recognise two kinds of eclampsia: (1) The more usual form associated with unhealthy kidneys and the imperfect elimination of toxins; (2) cases in which there was an excessive production of toxins, the renal elimination not being much less than normal. The present case was probably of the second type.

Dr. **Cullingworth** said that when more was known of the toxæmia of pregnancy, this case would probably form a link between the two conditions of eclampsia and acute yellow atrophy of the liver. He called attention to the large size of the infarcts in the liver, one of which measured about three inches by two and a-half inches in diameter.

Dr. **T. W. Eden** remarked that there was now much evidence to hand to show that cases of eclampsia would have to be grouped in two classes, the renal and the hepatic. The latter had not always been well recognised. He had given some attention to the experimental work that had been done on this subject; and the results were rather confusing. If it were admitted that the condition was due to toxæmia, they had only carried the question back one stage, for the toxæmia was a symptom of which they wanted to know both the cause and the nature. Thus the toxins might be the result, and not the cause of the hepatic changes. It was most important that they should get to know the nature of these toxins, and for the elucidation of this question they would have to look to the physiological chemist.

Dr. **Drummond Robinson** said that he had injected the filtered serum from one case of eclampsia into two pregnant guinea-pigs; they were in no way affected, but went through a normal delivery at term.

Dr. **Amand Routh** thought that this case differed from acute yellow atrophy, in that the liver was not atrophied. He had seen two instances of this disease, in both the liver dulness was markedly diminished.

Dr. **Williamson** mentioned a case rather similar in the one related, and Dr. **Bell** replied

(a) Read before the Edinburgh Medico-Chirurgical Society, July 2nd, 1902.

RETROPERITONEAL FATTY TUMOUR.

Mr. **Alban Doran** showed a specimen of a very large retroperitoneal lipoma. On the right side it was intimately connected with the kidney, which occupied a pelvic position, and was removed with the tumour. On the left side no trace of kidney was found. The patient died of suppression of urine. Mr. Doran briefly referred to the literature of the subject, which tended to show that these were most dangerous tumours to interfere with, as nearly every case operated on had died.

Dr. **Herbert Spencer** had met with a similar case, which also died soon after operation. The tumour was giving very little trouble, but it looked as if it could be removed without trouble, and this proved to be the case. But the patient died on the sixth day.

Dr. **Arthur Giles** remarked that the intimate relation of the tumour with the right kidney suggested the possibility that it might have arisen in the suprarenal capsule, and he asked Mr. Doran whether he had any evidence that shed light on this point. It would appear that there was little if anything to show the nature of these tumours before their removal was commenced, and once begun it was absolutely necessary to go through with it.

Mr. **Doran**, in reply, said that it was possible that the tumour originated in the suprarenal capsule, but a microscopic examination would be made to determine the question.

OVARIAN TUMOUR COMPLICATING DELIVERY.

Mr. J. W. **Taylor** (Birmingham) read a paper on this subject. The patient, æt. 30, was at the end of her second pregnancy, and an ovarian cyst impacted in the pelvis obstructed labour. He deliberated whether to remove it through the vagina or through the abdomen, but decided on the vaginal route. As soon as he had removed the cyst he applied forceps and completed delivery. The mother and child both did well.

The **President** thought that the objection to the vaginal route was that one might meet with a case in which one could not empty the cyst or draw it down into the vagina. He had seen a case in which he operated in this way; the cyst had three loculi containing pus. He could not completely empty the cyst, but delivered the child. The mother developed an abscess later on.

Dr. **Herbert Spencer** agreed with the President that the abdominal route was on the whole preferable, especially as it by no means necessitated Cæsarean section. In a case of his own he drew the uterus out of the wound, removed the cyst, and extracted the child with forceps in the usual way, while the uterus was out of the abdomen; he then replaced the uterus and sewed up. The case did well.

Dr. **Galabin** said that there was a third way of treating these cases, namely, by aspiration; he had done this in one instance, and then performed ovariotomy two weeks later. He was prepared to find that the tapping had led to the formation of adhesions; but this did not prove to be the case.

Dr. **Heywood Smith** remarked that eighteen years ago he had a case which he treated in the way suggested by Dr. Galabin, namely, by aspiration. He lost sight of the patient till she was again pregnant, and he then performed ovariotomy at the third month.

Dr. **Handfield Jones** said that he had had two cases of labour obstructed by a dermoid; the abdominal route was adopted in both cases; both had dense intestinal adhesions.

Mr. **Taylor**, in reply, said that it appeared to him that his patient was in a better position than Dr. Spencer's, since the latter had a long abdominal incision with a great risk of hernia; his own case had no scar.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, July 2nd, 1902.

Sir **Thomas Fraser**, President, in the Chair.

Dr. **Chalmers Watson** showed a case of lupus vulgaris under treatment by myelocene, and photographs of cases of psoriasis and lupus showing the results of treatment by this substance.

Mr. **Robert Purves** showed (1) Femoral artery ruptured by constriction of the thigh by running rope, the torn end of the artery sealed by natural arrest of hæmorrhage. (2) Section showing the deposit of iron in the tissues in the vicinity of a fragment of steel lodged in the forearm.

Mr. **Alexis Thomson** showed (1) Depressed fracture of the skull sustained twenty years before death. (2) Intestines showing strangulation by a band.

Dr. **Francis Boyd** read a paper on "Fallacies in the Copper Reduction Test for Sugar in the Urine," an abstract of which appears in another column, under the heading of "Original Communications."

Dr. R. A. **Fleming** read a paper on

THE PERIPHERAL THEORY OF NERVE REGENERATION,

with special reference to peripheral neuritis, which will be found on page 32.

Dr. H. M. **Church** read notes on a case of "Intestinal Fistula, probably Jejunal," which will be found under "Clinical Records" on page 34.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Provincial Meeting at the Children's Hospital, Manchester, held June 21st, 1902.

Dr. **Henry Ashby** in the Chair.

Dr. A. E. **Sansom** read a paper on

HEART DISEASE IN CHILDREN.

He said the chief affections of the organ were rheumatic but not always, and were not often associated with painful and diseased joints. The chief groups of them are: 1, the temporarily swollen and enlarged heart of rheumatism; 2, the heart of rheumatic pericarditis; 3, the heart of rheumatic endocarditis with resulting valvular disease; 4, the heart of slow and insidious rheumatic endocarditis inducing mitral stenosis.

Dr. E. **Cautley** showed a specimen of atresia of the conus pulmonalis and patency of the septum ventriculorum. The child died at twelve months of age from cardiac failure during an attack of dyspnœa. Dr. Cautley thought cases of congenital heart disease should be divided into two groups, those due to developmental error and those due to fœtal endocarditis. Occasionally the two factors might be co-existent. He regarded congenital syphilis as the first cause of developmental error.

Dr. **Theodore Fisher** thought the most striking feature of heart disease in children was pericarditis. Dilatation, slight in amount, occurring in rheumatism was not serious. He thought myocarditis and pericarditis showed that the heart was poisoned as a whole. He agreed with Dr. Cautley's classification of congenital heart disease. A patent foramen ovale was very common, and could be found in one-fourth of adult necropsies, if it were looked for.

Mr. W. P. **Montgomery** (Manchester) read a paper on the results of

TENDON-TRANSPLANTATION

in twenty-five cases of infantile paralysis of the lower extremity. The cases were classified into various groups, and the results of the various methods employed were given. The work of re-education was often very slow, but the final state good. A number of cases were shown in the wards prior to the meeting.

Dr. **Gwynne**, of Sheffield, read the notes of a case of

INFANTILE PARALYSIS OF THE LEG

which he had treated by excision of the knee, ankle and tarsal joints. The result was most satisfactory, and the boy could walk well though with a stiff leg, but without any evidence of deformity beyond some shortening.

Mr. R. **Clement Lucas** spoke of the old-fashioned way of treating such cases by tenotomy, with results which were not encouraging, and of the great advance of the present methods. He had himself done more in the way of excising the bone in the extreme cases of deformity than had been done in the present series.

Mr. **WALTER EDMUNDS** thought the cases were very successful, and regretted the shortness of the time at the disposal of the Society for discussion.

Mr. **JOSEPH COLLIER** (Manchester) agreed that the best way was to graft tendon on to periosteum if that could be done and the tendon were long enough. He had more experience of arthrodesis in cases where the limb was flail-like.

Mr. **R. CLEMENT LUCAS** read the following communication.

A CASE OF DISPLACEMENT OF BOTH TESTES IN PERINÆO,

with an inguino perinæal hernia on the right side. No deformity had been noticed till the sudden descent of a hernia on the right side at the age of three years drew attention to the displacements. A photograph showing the double displacement was exhibited. A radical cure of the hernia and replacement of the testes had been effected.

Mr. **SYDNEY STEPHENSON** related a series of cases in infants who while suffering from symptoms indicative of posterior basal meningitis became blind without ophthalmoscopic changes. Sight was ultimately completely recovered. The title of the paper was

FLEETING AMAUROSES IN CHILDREN PRESENTING SYMPTOMS OF MENINGITIS.

Mr. **R. C. DUN** (Liverpool) read notes of a case of

HYPERTROPHY OF THE RIGHT GREAT TOE,

showing radiograms, photographs and a cast of the foot of the case. The deformity occurred in a girl, æt. 7½, and no overgrowth was noticed until the child was five years old. The whole of the tissues of the toe were increased, the bones taking part in the hypertrophy. The greatest development was of a lipomatous nature. A definite fatty mass was present on the dorsal surface of the terminal phalanx.

Mr. **LUCAS** said many such cases of hypertrophy were nævoid lipomata, and asked if there was any nævoid condition of the toe, and Mr. **DUN** replied that there was not.

After a vote of thanks to the Chairman and the hospital authorities for the use of the hospital the meeting terminated.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 5th, 1902.

THE PATHOGENESIS OF BASEDOW'S DISEASE.

The *Deutsch Med. Zeitung*, June 26th, has a preliminary communication by Dr. Tedeschi on this subject.

The author has already performed the operation on the corpora rectiformis, not on rabbits but on young dogs, which appear to be very suitable subjects.

The result was that from three to five hours after the injury to the corpora rectiformis, sometimes even earlier, exophthalmos and tachycardia came on. There were always, in addition, general tremor and polyuria, glycosuria, and copious salivation. These symptoms increased up to the third day, and thenceforth they gradually receded. As regarded the behaviour of the pupils there was dilatation, but it disappeared quickly.

The autopsies showed that the most suitable spot for setting up the above-named train of symptoms was the anterior part of the corpora rectiformia just behind the tuberculum acousticum.

At the Medical Society's meeting, June 18th, a

CASE OF SPINAL TUMOUR TREATED BY OPERATION

was shown by Hr. Oppenheim.

A young lady of healthy family had a fall from a cycle, from which, however, no immediate injury was perceived. After some time, however, persistent pains appeared in the right hypogastric region, which resisted all efforts to remove them. Then appeared weakness in the legs, particularly in the right, so that the patient could only walk with difficulty. When the speaker first saw her there was scoliosis of the dorsal vertebræ, but no tenderness of the spines. There was anæsthesia of the right lower abdomen, flabbiness of the muscles, weakness of the legs, exaggeration of the reflexes. For a time she was under other treatment, during which extension was made which excited great pain.

On April 19th an examination was made in consultation with Hr. Jolly. There were then pains in the region of the ninth to the eleventh dorsal roots on the right side, only occasionally very severe. Scoliosis of the lower dorsal vertebræ, no tenderness on pressure on the processes. In the same region sensibility for nearly all stimuli was almost abolished. There was anæsthesia of the lip also, but it only extended 2 cm. upwards.

The abdominal reflex was absent below the umbilicus, but above it was weak on the right side, distinct on the left. There was reaction of degeneration on the right side.

In both legs there was spastic paresis, exaggeration of patellar reflexes, distinct ankle clonus. The gait was dragging, the patient only being able to walk a few yards, and that only with support. Micturition at times difficult. Diagnosis of a new growth in the spinal column was not difficult, but there was doubt as to the actual spot.

It was concluded that the upper pole of the growth lay in the region of the ninth dorsal root.

The eighth rib was therefore removed by Sonnenburg, the operation being rendered difficult by the scoliosis. As soon as the dura was reached, it sprang forwards, and when both succeeding vertebral arches were removed and the dural sac opened a tumour came into view, which encircled the cord from the right and behind, and was removed without cutting. The course of the wound was normal. At first there was free exit of cerebrospinal fluid, then came on constipation with meteorism from the fourth to the fifth day, and after that there was no further disturbance. All the symptoms improved within a few days. After a month she tried to walk, which she did very badly at first, but now without any trouble. The scoliosis also disappeared. The only thing now amiss with the patient is some exaggeration of the tendon reflexes and a diminution of the sense of position of the legs. The tumour was a benign one, but there is the possibility of others remaining.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 5th, 1902.

CONCUSSION OF THE BRAIN.

AT the meeting of the Prague Medical Society, Trnka gave a history of the epicrisis of a case he had under his care.

The patient was a soldier who received a kick on the side of his head from his horse. For three weeks after the accident the symptoms had all the appearance of simple concussion of the brain, which gradually improved, and to all appearance the man was convalescent.

Suddenly an apoplectic fit came on, followed by all the symptoms of bulbar paralysis, with motor paralysis of the extremities and glossopharyngeolabialis mischief, later on phenomena of the pons became prominent, and the patient died about two months after the accident.

The post-mortem examination revealed a hæmatoma about the size of a hazel nut in the right cerebral artery which extended to the medulla oblongata and pons. The kick had apparently been given on the mastoid process, and the vascular lesion been by *contrecoup* with subsequent or secondary apoplexy which determined doubt.

VAGINAL CARCINOMA.

Kleinhaus brought forward a case of carcinoma of the vagina, which he considered important owing to its atypical position on the anterior margin of the orifice. Along with this he exhibited a patient with inversion of the vagina, partial prolapses of the uterus, with elongated cervix. The prolapsed portion formed a swelling larger than the head of a child.

THE HEIDEN TREATMENT.

Frank next read a paper on Frenkel's treatment at Heiden. He said that Frenkel did not treat tabes dorsalis as such, nor the symptoms of ataxia, but aimed at the restoration of co-ordination, and as far as possible the recovery of the movements, while preserving the strength of the muscles. The latter part of this method is highly esteemed by Frenkel as the ataxic movement is a drag on the muscular force, and masks the feeling of weariness which allows the muscles to exhaust themselves and subsequently prove eminently dangerous to the life of the patient. He gives careful doses and keeps a rigid control over the frequency of the pulse; when it begins to rise the treatment is suspended. Frank related some of the cases he saw treated which were greatly improved in two or three weeks with three to five minutes twice a day. Although these patients were quite unable to stand at the commencement of the treatment after four weeks teaching they could walk with perfect confidence. Frenkel discards every sort of machine or apparatus in bed, and simply uses encouragement and practice on steps or extemporised stairs in a large hall where seats of different heights are arranged for different exercises.

In the discussion that followed Otto Wiener related a case of tabes which had been treated according to Frenkel's method, in which the patient during the treatment suffered from severe lancinating pain, which pyramidon, so highly praised by Frank, did not relieve while lactophenin cured it! It is fair to say that this patient had undergone the Nauheim cure with excellent results. While confined to bed he forgot the whole of his teaching for the tabes, and it is not at all comforting to know that Frenkel's treatment is so transitory.

Funke was in favour of apparatus, which he affirms to be quite indispensable to the successful treatment of the disease, as he has found by long experience that personal influence soon becomes inoperative in refractory cases. Again, the pulse frequency is no guide to the exhaustion of the muscles.

THREE performances of "The Gondoliers" will be given on July 10th, 11th, and 12th, at Ladbrooke Hall, Notting Hill, on behalf of the funds of the Tottenham Hospital.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

BRIDES-SALINS.

UNDER the name of Brides-Salins are included two spas ("Brides-les-Bains and Salins-Moutiers"), about two miles apart, and quite different in character of waters, but under the same management.

Brides-les-Bains is the more prominent; the chief hotels, Casino, the Direction of the Company, and the residences of the French and English physicians being here. It is situated at an altitude of 1,900 feet, in a charming valley of the Tarentaise Alps, and at the junction of two impetuous mountain streams. Environed by green hills and woods, in an atmosphere ozonised and vivified amidst the mountains, and offering in its near vicinity a variety of Alpine excursions, easy or difficult, as each visitor may prefer, with the daily music and other *diversions* common to Continental summer-resorts, and the choice of half-a-dozen good hotels, Brides annually attracting greater attention.

It is by no means a new thermal station. From the vestiges of Gallo-Roman thermes it was evidently known in the imperial days of Rome, and there are records proving its popularity in the sixteenth and seventeenth centuries. The springs appear to have been diverted and lost by mountain avalanches or cataclysms about the commencement of the eighteenth century, and not to have been re-discovered until early in the last century. We find them mentioned by a traveller in 1817, and in 1830 they were again publicly used. Since then, but very slowly, Brides has gradually risen in appreciation, but even to-day it is by no means as well known or as much appreciated as the genuine merits of its mineral waters deserve. Especially to the British and American public is it far too little known, and particularly so to those who frequent the Carlsbad and some other similar springs. Brides is more readily reached from London and Paris, more attractive in its surroundings, less costly in every way, and less violent and dangerous in its effects.

The mineral springs at Brides come to the surface on the left bank of the Doron River, and have a specific gravity of 1¼° Baume, and a temperature of 95° Fahrenheit. Their mineralisation is 6·18 gr. per litre, and their flow 80,000 gallons in twenty-four hours. They contain sulphates, chloride of sodium, and magnesia of iron. In each litre are 5·09 gr. of purgative salts (sulphates of soda, lime, magnesia, &c.) The French medical authorities state them to be *toni-purgatives, chlorurées-sodiques, magnesiennes, calciques;* and recommend them specially for liver maladies, abdominal enlargements, gastric troubles, dysentery, constipation, urinary catarrhs, hæmorrhoids, cerebral congestions, migraines, anæmias, heart diseases, hypertrophy of the spleen, diabetes, and obesity.

From the efficiency of its waters in cases of obesity and diabetes it has long been customary on the Continent to call Brides "the French Carlsbad." To this title more recently has been added the claim to be styled "the Nauheim of France," because of the successful treatment here of heart diseases. Taken in small quantities of one to three glasses the Brides mineral-waters are tonic and aperitive; taken in larger quantities (of four to six glasses) they are laxative, purifying, purgative, and diuretic.

In his report to the French Government in 1874, Dr. Jules Lefort states:—" The great peculiarity about these waters is their complete and inimitable union of purgative and tonic properties. This double action favours the secretions and the circulation of the digestive tube and its adjoining parts *without debilitating* (as might otherwise be the case with saline purgatives often repeated); and, on the contrary, building up again the constitution by exciting appetite, and *without injury to the state of the blood or to nutrition* (as with alkaline waters and carbonates of sodium.)"

For this reason it is claimed these waters may be drank and well-digested for a long time, a great advantage over other mineral waters too irritating in their action to be continued many days successively.

In his able treatise on the mineral waters of Savoy, the late Dr. F. Bertier, of Aix-les-Bains, recommends a sojourn at Brides as an admirable *after-cure* for those who have taken a course of treatment at Aix; and also Brides-Salins as health stations eminently efficacious for all who, having long resided in hot climates, suffer from liver and spleen complaints.

The Operating Theatres.

ROYAL FREE HOSPITAL.

Acute Appendicitis.—Mr. E. W. Roughton operated on a man, æt. 19, who had been admitted with a history of pain in the abdomen of three days' duration. On admission to the hospital his symptoms were but slightly marked, and during the first two days he steadily improved, both the temperature and the pulse becoming almost normal, but on the third day his pulse became much more frequent, the temperature again rose and his general condition became decidedly worse. An operation was therefore decided upon. On opening the abdomen in the right iliac region a small abscess containing two or three drachms of pus was evacuated and the stump of the appendix was visible, the extremity of it having sloughed off. The affected area was not completely shut off from the general peritoneal cavity. Gauze drains were inserted and the wound left open. Mr. Roughton said the great point of interest was the deceptive appearance of convalescence after admission; he certainly thought the patient would get well, and that the usual operation for removal of the appendix might be performed in the course of a few days, but this expectation was quite falsified by the subsequent progress of the case. He regarded the prognosis as grave on account of the bad general condition of the patient, and the fact that the general peritoneal cavity was not shut off. Although the stump of the appendix presented in the wound he did not remove it because he thought the risk of so doing would be greater than the advantage the patient might derive from it.

The man died two days afterwards, and the post-mortem showed that there was a large collection of pus in the pelvis. Mr. Roughton thought that, looking back on the whole case, it would have been undoubtedly better in this instance if the operation had been performed at once on the patient's admission. The case he considered really afforded an argument in favour of the American practice of immediate operation in all acute severe cases of appendicitis.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 9, 1902.

MODERN VIEWS ON APPENDICITIS.

At the meeting of the American Medical Association, which took place early this month, the perennial subject of the treatment of appendicitis received, as usual, a large amount of attention. The mortality does not appear to have been influenced in any appreciable degree by the age of the patient, the prognosis depending upon the condition of the parts in respect of abscess formation, gangrene of the appendix, co-existing peritonitis, and local damage. Further illustrations were afforded of the insidiousness with which apparently mild cases become purulent, the ordinary symptoms of suppuration being either absent or so trivial as to escape attention unless specially looked for. Most surgeons now examine the blood in order to infer the presence of pus from leucocytosis, although, according to American views, the surgeon ought not to wait for suppuration to take place before operating. We do not attach the importance which some surgeons do to the great difference between the mortality of operations undertaken during the acute and the chronic stages respectively, because the very existence of an acute appendicular abscess constitutes such a great element of danger quite apart from the question of the operation. In time to come, no doubt, the fact of an attack of appendicitis having been allowed to progress to the stage of suppuration will be held to imply either that the patient has failed to seek assistance in time or that the practitioner has failed to do his duty. Another point of interest is the extremely small proportion of cases of appendicitis in which recovery is not followed by subsequent recurrence, even a violent attack often failing to secure such immunity. No two cases of appendicitis appear to be exactly alike, and this variability, which applies equally to the symptomatology and to the anatomical relations of the parts, explains the long list of difficulties which are apt to confront the operator. One disadvantage of operating after suppuration has taken place is that the circumstances rarely allow of the operator discovering and removing the diseased appendix, thus leaving a focus of infection behind, a fact which greatly affects the prognosis in such cases. Moreover, the damage which suppuration causes to the neighbouring structures often entails subsequent trouble, among which ventral hernia is one of the most frequent, though not the most dangerous. It is urged that the use of the ambiguous term "perityphlitis" ought never to be used, in that it merely states a clinical fact without specifying the exact nature of the mischief. It is open to question whether there be such a disease as perityphlitis apart from appendicular infection, and the use of the less distinctive term is apt to blind the practitioner to the precise significance of the lesion. The expectant attitude is still in favour in this country, and it would be interesting to compare the statistics of American surgeons *en bloc* with our own, although it must be admitted the marked individuality of cases of appendicitis renders accurate data for comparison almost impossible to procure.

QUACKS AND QUACK MEDICINE.

DURING the recent debates in the Commons upon the Midwives Bill the protection of the public against unskilled practice formed the main basis of the supporters of that measure. If that principle is to be logically followed up by the Legislature the attention of Parliament will speedily be directed to irregular medical practice and the sale of quack and patent medicines. Those two evils together cause an incalculable amount of harm to his Majesty's lieges in all parts of the Empire. It seems likely, moreover, that these nefarious industries were never in a more flourishing state. Quack specialists for skin, cancer, rheumatism, diseases of the eye and nervous system, bonesetters, herbalists, and a host of other parasites infest the rich and fashionable quarters of our great towns, while whole fortunes are spent in the simple advertising of this or that nostrum, which professes to cure one or more, perhaps a dozen, serious disorders. Curiously enough, there never was a time when legitimate medicine had reached a sounder and more comprehensive knowledge of diseased processes and of the powers and the limitations of curative methods. At this precise point in the world's progress, however, shameless and wanton imposture is carried on without let or hindrance in our midst. The police look on with indifference, and Government takes no heed of the matter, except to legalise the introduction of a new class of hybrid medical practitioners in the shape of licensed midwives. Surely if the parturient woman is worthy of protection against the pretensions of ignorant midwives, so also should the patient afflicted with cancer or deafness be protected from charlatans. Yet numerous unqualified ear and eye practitioners drive a thriving trade in the United Kingdom, although the two branches of practice involved demand the highest development of special skill and training, and are fraught with the gravest results to patients themselves. Infallible cures for kidney disease are freely advertised, although it is certain from a medical point of view that there is no cure for chronic renal affections. What have the sentimental upholders of the Midwives Bill to say of the sale of nostrums warranted to cure incurable kidney diseases? If they are right in protecting parturient women, surely they would not be wrong in protecting the large section of mankind afflicted with chronic diseases of the kidney. There would be no need to apply for any great amount of fresh legislation were our police to use the powers already vested in their hands. Were the police to follow up carefully the records of the police and the coroner's courts, and systematically to inquire into all suspicious advertisements, they would find no lack of cases in which to prosecute. The registrars of births and deaths, again, might furnish valuable information to the police. It seems not unlikely, moreover, that an immense amount of good might be done by prosecutions for obtaining money under false pretences, an offence which is committed by every charlatan who claims to cure incurable conditions. In Germany, it has been estimated that in ten years the population has increased 58 per cent., regular medical men 76 per cent., and quacks 1,567 per cent. Of 123 such unqualified persons summoned in Berlin, thirty had been domestic servants, forty-five artisans, sixteen clerks, and twenty-four had a fairly good education. Of 130 female quacks, only one was an educated person, sixty had been servant girls, twenty-four dressmakers, ten charwomen, and five nurses. Nearly 30 per cent. of the men had been in gaol, and of the women 15 per cent. More than 100 samples of quack medicines were analysed by the police, and over 80 per cent. contained elements of absolutely no medicinal value. From such sources the army of unqualified practitioners in Germany is drawn and equipped, and there is good reason for believing that investigation would reveal much the same state of affairs in the United Kingdom. Clearly, the education of the people, about which so much is heard nowadays, has not yet matured the popular judgment in the matter of the treatment of disease. An amendment of the Medical Acts whereby the control of unqualified practice should be made a reality, would yield more solid benefit to the community than a score of wars in remote corners of the world.

INJURIES OF VEINS.

IN selecting the surgery of the circulatory system as the subject of his Introductory Address before the Royal Academy of Medicine, Madrid, His Excellency, Dr. Don Alejandre San Martin y Satinstegal made choice of a subject that has not received the attention it deserves, and one well calculated to call into play his familiarity with European medical literature, past and present, and it is interesting to note in this connection he credits Lambert, an English writer of the eighteenth century, with the credit of introducing the surgical treatment of wounds of veins. The tolerance of veins to surgical interference is the keynote of the address. For untold years, from the rude Celt surgery of prehistoric man down to the days of the country phlebotomist, who traversed the country practising phlebotomy every spring and autumn, and spaying pigs, human veins have been submitted to the rudest surgery and withal, how seldom was phlebitis found to follow the injury. Accidental wounds of the veins in which the flow of blood was arrested by pressure, oftimes applied in the way well calculated to produce inflammation, yet how seldom has it followed, even in cases of injury to the jugular, iliac, or femoral? Lambert pondered on these things, and meeting with an aneurysmal varix he operated by joining the extremities of the vein together and the extremities of the artery. His operation was a success, but unfortunately others were not so successful, and the operation and the book of Lambert passed from memory. There were, however, still surgeons who thought for themselves, and Czerny in a case in which the internal jugular was wounded (1881) put in a few sutures; unfortunately the patient succumbed to septicæmia, and for years no further attempt was made to suture a wounded vein until Schede (1892) sutured the femoral, and soon afterwards the lateral wall of the inferior vena cava. Operative interference in wounds of veins was, however, not firmly based on a scientific basis until Burci (1894), at the International Surgical Congress in Rome, demonstrated the regenerative process in wounds of veins. They form a thrombus intra- and extra-vascular which quickly and firmly becomes organised. Señor San Martin himself has placed on record one of the most successful and brilliant of these operations by reuniting the cut extremities of the axillary vein, which was wounded in the removal of an enormous subscapular angioma. In none of the cases of operation on the internal jugular, femoral or axillary, was there secondary bleeding, thrombosis or emboli as a result, and in not a single case did air enter into the blood currents. There is no occasion to multiply illustrations of the safety and facility with which the operation may be performed. But we cannot refrain from describing, though briefly, the ingenious method of Knemmel, who, in excising a large neoplasm that extended across the thigh immediately inferior to Poupart's ligament, found he had wounded both an enlarged femoral and saphenous vein. Both vessels were cut across. He immediately clamped them and sutured the cut extremities, and then surrounded the vessels at their point of juncture with a fine layer of sterilised gum. Payer (1901) has since then, in the case of a patient of seventy-seven years old, when excising a malignant tumour, cut the femoral vein, invaginated the extremities, sutured them, and placed at the point of suture a very thin magnesium ring. Thus we find that almost two hundred years after his book appeared Lambert's rational method of treating injured veins is once more publicly advocated, and in all the principal Continental schools his teachings are bearing fruit; but at home with us it has never secured that recognition as an accepted surgical procedure that the distinguished orator, Señor San Martin, claims for it.

Notes on Current Topics.

The Operation upon the King.

The objectionable report of the operation upon his Majesty the King to which publicity was given in the issue of the *World* newspaper for July 2nd, has been the only discordant note sounded amid a nation's deep sympathy for the illness from which the King is now happily recovering. Not only did the imaginative account seek to minimise the skill and discount the responsibility of the operating surgeon, but it also sought to show that the procedure was one, so trivial in itself, that the reports as to the King's fortitude and resolution were unnecessarily exaggerated. We cannot understand how any public journal, professing to deal with facts, could have given currency, at such a time, to statements alike untrue, ill-natured, and irresponsible. Who was it who inspired the report? In seeking an answer to this query one is led to believe that it must have either been an individual who expected to receive a title from the King, and was disappointed, or it was a member of our own profession who, jealous of Sir Frederick Treves's handiwork and commanding position, was intent upon diverting from Sir Frederick some of that praise and recognition of services rendered which the public have bestowed on him. We can, however, only trust that our last surmise is incorrect, nevertheless, it is regretful to have to admit that medical men in their professional relationship towards each other, are not always given to displaying the best side of human nature. As a last word upon this scandalous incident, we may say that the Editor of the *World* has reason to be thankful that he is not a German subject and that his newspaper was not published in Germany, for if that had been the case, and he had published such a report of the German Emperor, quite likely he would now be under arrest.

The History of Enterectomy.

It is always interesting to follow the development of any surgical operation, beginning with its earliest and crudest form, and coming down to its latest and most complete adaptation. Nowadays we are too apt to look on surgery as being almost a modern art, incapable of great perfection were it not for the discoveries of anæsthetics and antiseptics. In no field is this more true than in that of abdominal surgery, and it comes on us as a surprise when we find that suture of wounded intestines was practised fifteen centuries before Christ by Egyptian and Arabian surgeons, who used the mandibles of black ants to bring the surfaces together. At the same period fumigation of the uterus was not an unknown treatment, forestalling what has recently been introduced as a new practice—the use of superheated steam in catarrh of this organ. From the time of Celsus, however, who details a method of suture of the intestine, little progress was made in the operation of enterectomy until Ramdohr, in 1727, successfully removed two feet of gangrenous gut. Bell, in 1794, improved on his method, and Lembert, in 1826, introduced the suture, which is still the favourite with most surgeons. Meanwhile, a year earlier, Reyhard used for the first time a mechanical aid in the shape of a flat plate of wood, which is passed with the fæces as soon as the sutures are cut, some days after the operation. In a paper by Dr. Stirling, of Melbourne, in the last number of the *Intercolonial Medical Journal* to hand, the later devices are enumerated in a tabular statement. There are, it appears, no less than twenty-one more or less different forms of suture, several methods of invagination, and twenty-nine kinds of mechanical aid, all in use at the present time.

A Layman's Advice to Doctors.

IT is often well to attempt to see ourselves as others see us. There is doubtless some reason in the oft-quoted remark that "doctors are more ready to give advice than to receive it." And yet it is true that medical men are widely criticised and their methods and manners openly discussed. It is impossible to live regardless of public opinion, and unwise to bolster up any custom or procedure under the sheltering "etiquette of the profession," unless such is for the good of all, and particularly in the best interests of sick humanity. We therefore venture to welcome the open criticism and kindly presented "advice" contained in a recent number of *The British Weekly*, the editor of which remarks that: "No one will dissent from the view that a fuller knowledge of human nature would make doctors or some of them, even more helpful than they are, and one way would be to listen attentively to what patients say about themselves. People can never be made to believe that they do not know more about themselves than anyone else can know. They delight in describing their sensations, in giving their family history, in laying the whole story of their hopes and fears before their adviser. We are told that there are many patients who simply want to be taken in hand and told what they should do. They have fallen into such a perplexity about life that they distrust their own judgment in every point, and they want a strong and skilful man to take charge of them, to make up his mind what they should do from the beginning of the day to its close, a statement the wisdom of which will be appreciated even to the youngest in the profession. Even more to the point: Whatever doubts and misgivings a physician may feel—and he must often be troubled by them—he should not show them. He should appear to be a man who knows his way. By watchfulness, no doubt, the truth will gradually be discovered, and many patients cease to trust their doctors because they have told them that the ailment perplexes them. The author's remarks anent the reluctance of certain medical men to accede to the desire of the friends for a second opinion, apply, we believe, to the very few. Perhaps the only part of this delightful essay to which any exception could be taken is that which deals with the "rule of the medical profession never to advertise." The article is sympathetic and may be read with advantage by all young practitioners; indeed, it may possibly save them many a disagreeable experience.

The Motor-Car in Medicine.

SOME time since we pointed out that when judiciously employed the motor-car might prove of immense service in the treatment of consumption and certain other affections. *The Car* now discovers that motor-car driving at a speed well up to the legal limit is specially suitable to those with consumptive tendency or those actually suffering from phthisis and may be of service in cases of insomnia, "liverishness," anæmia, "colds in the head," and for "persons who are suffering from worry and require their thoughts to be carried into pleasing and interesting channels." We hope that such like foolish and reckless advocacy will not hinder the proper use of motor-cars in the treatment of disease. There can be no doubt that the motor-car provides a means of regulated and quiet locomotion which might prove of the greatest service to many invalids and convalescents. We think many a hospital for the sick, institution for the crippled, and asylum for the mentally and physically feeble, would do well to add a suitable motor-car to the general equipment. To the sanatoria for the phthisical poor a motor-car would prove a most useful accessory. When our hospital authorities have learned the wisdom of establishing country branches the motor-car may be expected to solve many of the difficulties connected with the transit of patients, staff, and stores. Already medical men, the most conservative of mankind, are realising that in the motor-car they have the cheapest and most convenient form of carriage for all-round work. But as with drugs so with motors there is much judgment needed in the selection.

The Bibliography of Appendicitis.

AT a time when the calamitous malady of the King has drawn attention to that little appendage which Talamon has so fitly described as "un organe inutile et inusible," it is interesting to note that it is chiefly through the researches of English and American doctors that the various morbid conditions connected with the vermiform appendix have been brought to light, and measures for effectual treatment rendered possible. Dr. R. H. Fitz in 1886 furnished the first of the modern series of monographs on the subject, and introduced the term "appendicitis." Sir Frederick Treves, as far back as 1888, published an important communication on relapsing typhlitis treated by operation; and, as all the world knows, his subsequent work has been one of the chief means of elucidating the perplexities connected with the vagaries of the long-neglected cæcal appendix. The first book to be published on this subject was that written by Dr. T. N. Kelynack on "The Pathology of the Vermiform Appendix," and issued in 1893. It gives a full bibliography of all affections connected with this intestinal appendage up to 1893. Dr. Hawkins' work on "Diseases of the Vermiform Appendix" followed in 1895. In 1900, Mr. A. H. Tubby issued his concise little essay on "Appendicitis" in the "Medical Monograph Series." In the following year Mr. W. J. Walsham, of St. Bartholomew's Hospital, published some suggestive papers in THE MEDICAL PRESS AND CIRCULAR on "The Treatment of Appendicitis," which were reprinted in book form, and Mr. C. B. Lockwood issued some recent studies on "Appendicitis: Its Pathology and Surgery." Among recent American works that of Dr. John B. Deaver might be referred to, as well as a "Review of the History and Literature of Appendicitis," by Dr. George M. Edebohls, which appeared in the New York *Medical Record* for November 25th, 1899. Of course this must not be taken as a complete bibliography of the subject, but it is sufficient to show that it has attracted considerable attention of late.

Primitive Medicine.

MEDICINE and surgery are older arts than most people imagine, and there is probably no race, no matter how backward, which has not developed them to a high degree, if not always in the most fruitful direction. It has been recently pointed out that even as long ago as the Neolithic age, trephining was a common surgical operation, and out of twenty trephined skulls of that period examined by Dr. Prunieres, only one did not show signs of healing. M. Broca believes that the principal object of the operation was the cure of epilepsy. Even among birds a certain rude surgery has been noticed, for the snipe is known to set broken bones, and certain anthropoid apes were seen by Livingstone to stop bleeding by pressure of their fingers. Dr. Colquhoun, in his Presidential address to the New Zealand branch of the British Medical Association, has recently enumerated some facts of primitive medicine collected by various observers among the aborigines of Australia and the South Seas generally. Thus wounds are treated by a thorough sucking, followed by the application of *pridgerong*, a kind of resin exuding from the bark of trees. Abscesses are poulticed and lanced. Cold water baths and bleeding are practised in fevers. Two cases of tetanus are recorded as having recovered, the treatment being the formation of a urethral fistula. There is a wide-spread knowledge of the vegetable materia medica, certain plants being known for their cathartic, astringent, or emetic qualities. Side by side with these scientific practices is the belief that therapeutics is a magical art, and most therapeutic processes are accompanied by considerable ceremonial which is considered of great importance.

The Cocaine Habit.

MOST of us have at one time or other been brought into contact with the victim of the cocaine habit, and in too many cases it is feared that the taste for this drug has obtained its first hold by its injudicious administration by a medical man. Indeed, this remark holds true of other and commoner drug habits, such as the abuse of morphia and chloral, as well as of cocaine. Perhaps in no class of the community is the habit more to be found than among medical men and apothecaries, who, of course, have the easiest access to such drugs. In India, however, we learn that the cocaine habit is by no means confined to such classes, but is gradually spreading through all ranks of the native world. It seems that there is practically no block in that country on the sale of this poison, and that it can be bought in any quantity from the pettiest vendors in the native bazaars. It is bought in cheap confections by schoolboys, but its greatest consumption is among the girls and women of the zenanas. It is impossible to exaggerate the moral and physical ruin of the victim of this drug, the habitual use of which is much more deadly than that of either opium or alcohol. We quite agree with our contemporary, the *Indian Lancet*, that the time has come when Government must grapple seriously with the evil, and no matter what difficulties stand in the way, make the abuse of cocaine an impossibility in India.

The Exercise Value of Dancing.

DANCING is a pastime proper to the seasons unfavourable to outdoor sports, and apart from its social advantages it is entitled to regard if only by reason of the muscular exercise which it entails, since this is indispensable to health. A correspondent, also an amateur statistician, has taken the trouble to calculate the distance covered by dancers in their gyrations. He finds that a valse of average duration represents approximately a run of a thousand yards. This is the longest dance, with the exception of the quadrille, which, with its four figures, covers nearly 1,800 yards. The mazurka is only equivalent to about 900 yards, and the polka to 800, while the lazy *pas de quatre* is barely 700 yards. Carrying his statistical ingenuity still further he estimates that the usual series of dances at an ordinary ball, beginning at 10 p.m. and finishing at 5 a.m., represents no less than 56,000 steps, equivalent to nearly 25 miles on level ground. Admitting that the dancers are few in these degenerate days who go conscientiously through the entire list of dances provided for their entertainment, the fact remains that each man (and woman) who does his (or her) duty accomplishes a very respectable amount of exhilarating exercise. The value of exercise from a physiological point of view is greatly enhanced by its exhilarating effects, and this is one reason why the daily "constitutional" fails to yield the health-giving effects of cycling, golf or dancing, the only drawback to the last named being the lack of fresh air and sunlight, which add so materially to the enjoyment and salutary effects of all forms of outdoor exercise.

Persistence of Infection in Typhoid.

IT is a matter of great importance, both to the practitioner and to the medical officer of health, to have some test as the length of time for which infection persists in the various infectious diseases, and perhaps there are few points on which there is so little agreement or certainty. Thus the diphtheria bacillus has been found in the mouths of children months after they have recovered from the disease, though it is of course possible that the organisms have so far lost their virulence as to be practically non-pathogenic. In typhoid, too, it is as a rule difficult to find the bacilli in the fæces at any but an early period of the disease, and it was consequently assumed that the infectivity has diminished and disappeared early. This convenient assumption, however, received a blow when it was shown that the bacilli appear in the urine up to the seventieth day of the disease and often much later. An outbreak of milk-born typhoid reported by Dr. Jamieson, the Health Officer for Melbourne (*Australasian Medical Gazette*, April, 1902), bears out this belief in a prolonged duration of typhoid infection. A dairy-keeper who became ill on December 1st, 1900, returned home from hospital on January 15, 1901, but did not immediately start work. On March 4th, however, a case of typhoid was reported, which in common with five others within a couple of weeks, were undoubtedly traced to the milk supply from this dairy. In this case, assuming that the infection was due to the case of December, as seems almost certain, the infectivity lasted for nearly four months from the beginning of the disease.

A Dangerous Disinfectant.

THE available number of desirable disinfectants is extremely small, and there is a wide field still open to scientific chemistry in that eminently practical direction. The drawbacks of such substances commonly lie in their poisonous and irritant nature, their insolubility, bulk, unpleasant smell and other physical inconveniences. Explosiveness, however, is one of the last charges we would expect to have levelled against a disinfectant. For all that, it appears that chlorinated lime is open to that objection. When freshly made the powder is somewhat unstable, and if packed before a sufficient time has elapsed to allow of its gaining a condition of stability, it is apt to become explosive. This fact came into unpleasant prominence when, last November, the wife of a Commander in the Navy opened a tin of chlorinated lime bought from the Army and Navy Stores, London. The stuff flew into her eyes and did a good deal of damage, which, happily, it seems, will not be permanent. There was the usual conflict of expert evidence at the ensuing trial in the King's Bench Division, but the jury awarded the plaintiff £172 as *solatium*. It may safely be assured that manufacturers and vendors of chlorinated lime will take care that the stuff is properly seasoned before being packed.

Coronation Stands and Hospitals.

THE approach of the Coronation saw London covered with enormous stands along the line of route of the procession. Among others desirous of making a little hay out of the brief spell of sunshine they afforded in these latter days of depression were those hospitals fortunate enough to command a view of the proceedings. The postponement of the ceremony has placed these particular institutions in a somewhat awkward position. Their only course has been to offer to return the money paid for seats less 10 or 15 per cent. to meet expenses. In many, if not in most cases, however, the purchasers will doubtless allow the money to remain in the hands of the hospitals. Another point of some importance is the retention or otherwise of the stands. If, on the ground of the costliness of erection they are allowed to remain *in situ*, in the hope that the Coronation will take place in September or October, both the hospitals and the public will be put to a good deal of inconvenience. Moreover, there is an ever present danger of fire in the existence of these large wooden structures built against the walls of the hospitals. In these dog days the wood will become dry as tinder. If they are allowed to remain special precautions should be taken as regards fire not only in the stands themselves but also in the adjacent hospitals.

The Midwives Bill.

THE Bill has passed the Committee stage in the House of Lords, where the provision was agreed to that after January 1st, 1905, the assumption of the title of midwife, or any name implying that certification under the Act, shall be punishable by a fine of £5; and that after January, 1910, no woman shall "habitually and for gain" attend women in labour unless she is certified under the Act. Provision was also made to divide the Register of Midwives into two sections, to distinguish between the qualified and merely registered women. The words rendering it compulsory on the Privy Council to submit rules to the General Medical Council before approving them was modified, and as it stands the Privy Council will only be required to "take into consideration" any representations made by the Medical Council. It was also made the "duty" of the local supervising authority to suspend any nurse when necessary "in order to prevent the spread of infection." An amendment was also agreed to allowing any woman who thinks herself aggrieved by any decision of the Midwives Board to appeal to the High Court within three months of any decision, such appeal to be final. The Bill as amended was then reported to the House.

Arsenic in Medicine.

Of late years the fashion of giving arsenic in medicine has considerably diminished. Even in dermatology, where formerly in many schools arsenic formed a sheet-anchor among remedies, the drug is now comparatively or altogether neglected. That result is not to be wondered at, considering the notoriously damaging effect of the metal upon excretory organs, to say nothing of nervous and other internal structures. The arsenical beer-poisoning epidemic of 1900 and 1901 is likely to set the minds of medical men thinking, as well as those of their patients. If arsenic in the extremely small quantity of two grains to a gallon of beer is sufficient to set up distressing, dangerous and sometimes fatal illness in a consumer, what is likely to be the result of courses of arsenic given in physic, and kept up over long-continued periods of time? In his report recently presented to the Royal Commission on Arsenical Poisoning, Professor Delépine mentioned the following formidable changes as common among the victims of arsenical beer: (1) general hyperæmia, most noticeable in the lungs, glands, muscles, and nerve centres; (2) considerable degeneration and wasting of some of the muscles examined; (3) albuminous and fatty degeneration of the heart muscle; (4) more or less complete disappearance of fat from the cells of fatty tissue; (5) albuminous and fatty degeneration of glandular epithelium, specially well marked in the liver; (6) degeneration of nerve tissues, most marked in the nerve-cells of the cerebral cortex and the spinal cord. On the whole case Professor Delépine concluded that the epidemic of 1900-1901 was due to arsenic in beer, derived from arsenical glucose used as a malt substitute. The presence of smaller quantities of arsenic, such as sometimes arose from badly prepared malt, might be injurious in weakly persons. Bad results were more marked among classes of persons exposed to poor feeding and other deteriorating influences.

Kernig's Sign.

It is now nearly twenty years since Kernig described the phenomenon which has since been referred to as Kernig's Sign. He made no attempt to explain the nature of mechanism by which it is produced, nor did he claim that it was pathognomic of meningitis. It still remains a subject of investigation; notwithstanding that a great number of theories have been formulated to account for its occurrence, none have so far received any very wide amount of support. The number of cases of meningitis of all kinds, including those of epidemic cerebro-spinal, in which the sign has at no time been present, is daily growing larger, as is also the list of cases of disease other than those affecting directly the brain or meninges in which the sign has been present. Dr. Lailer believes that it may occur as a symptom of fæcal encephalitis, and may then be present on the opposite side only of the body Further, that the most reasonable explanation is to ascribe it to an irritative lesion of the pyramida tract that diminishes but does not destroy its functional activity.

Pregnancy and Tuberculosis.

Repeated pregnancy is well known to create a marked predisposition to tuberculous infection, no doubt by reason of the depreciation of vitality which it determines. On this ground Dr. Hamburger, of Berlin, advocates the induction of abortion in pregnant women who are manifestly tuberculous. From a purely scientific point of view the suggestion has much to recommend it in that it is generally recognised that we are justified in sacrificing the life of the unborn child in the major interests of the mother, and, moreover, because the children of tuberculous parents are by heredity often doomed to an ephemeral existence. It may, however, be urged of tuberculous mothers that it is a common experience to see them resist the disease during the child-bearing period only to succumb at or towards the advent of the menopause. It is highly improbable that this principle of treatment will ever be generally adopted, though public opinion is gradually tending to condemn the marriage of tuberculous subjects. No legislative measures can be trusted to grasp the problem involved, and it can only be by educating individuals to a proper conception of their responsibilities and their duties to generations as yet unborn, that we can hope to bring about a reaction against these marriages, so prolific in misery to individuals and degeneracy of the race.

Opium in Childhood.

The fact that opium produces such marked toxic symptoms in childhood has almost banished this most valuable therapeutic agent from the list of drugs used in diseases of childhood. The effect of opium on a healthy child or one suffering from some minor ailment is wholly unlike the effect it produces in such serious complaints as enteritis or cholera infantum. The older writers were in favour of giving the young patient one good dose, and Scotch physicians usually combined the drug with ammonia. Once more the use of opium is recommended in children's diseases by M. J. A. Cueto, whose recommendation is supported by our contemporary *El Siglo Medico*. We hope that the unnerving fear of the drug is passing away and that children will not be deprived of this potent and valuable medicine.

The Pharmacy Act.

An amended Order has been issued by the Privy Council adding "liquid disinfectants" to the list of poisons which, together with "liniments, embrocations and lotions," must be sent out in bottles distinguishable by touch and duly labelled.

Rebuilding of Manchester Royal Infirmary.

After about a quarter of a century's discussion and a twelve years' battle of sites, the Board of Management of the Manchester Royal Infirmary have recommended that a new hospital on "pavilion" lines should be erected on the present site and arranged to provide 452 beds and accommodation for 230 officers, nurses, and servants. The ground is of very limited extent, in a crowded, noisy, dusty, and in many other ways unsuitable part of the city. When hospitals and other institutions for the sick and afflicted in London and other cities are learning the importance of a departure into the country, and are realising the danger of crowding sick together on limited space and in city atmosphere, it seems short-sighted policy for Manchester to expend £200,000 in erecting a new infirmary on an old and unsuitable site, and in the midst of the worst possible climatic conditions.

Lumbar Puncture and the Means of Avoiding its Dangers.

Lumbar puncture, even apart from the injection of drugs into the spinal canal, is an operation by no means devoid of risk. Experience has shown, in too many instances, that the simple withdrawal of a small quantity of cerebro-spinal fluid is capable of causing, and indeed almost invariably determines, more or less troublesome symptoms. The operation may give rise to vertigo, faintness, and apoplectiform attacks, &c., symptoms directly due to a disturbance of intra-cerebral pressure, and the withdrawal of fluid is often followed by obstinate headache, vomiting and acceleration of the pulse. Dr. Milian, of Paris, points out that these more or less distressing consequences may be avoided by certain simple precautions. First of all, it is important to allow the fluid to escape spontaneously, no aspiration being employed. The quantity withdrawn ought never to exceed one or two cubic centimetres, and the flow should be arrested directly the patient evinces the slightest manifestation of discomfort. The patient moreover should be kept in the horizontal position for several hours after the operation, while in presence of any disquieting symptoms the head must be placed low and ether or caffeine injected. He claims that by these means all risk of dangerous complications may practically be averted, and as the operation is one which seems likely to be frequently resorted to for diagnostic purposes his suggestions are worthy of note.

Cardiac Paralysis under Chloroform.

In a number of cases in which death has taken place suddenly in persons under chloroform the only abnormalities discovered at the post-mortem examination have been enlargement of the thymus, with or without a concomitant enlargement of the spleen. This condition, which is often associated with hypertrophy of the follicular glands at the root of the tongue, has also been met with in several cases of death under ether as well as in cases of sudden death from trivial causes (cold bath, the introduction of a tongue depresser, &c.) apart from the administration of any anæsthetic. There seems to be reason to suspect a relationship between this anatomical abnormality and cardiac paralysis of sudden advent, but our ignorance of the function of the thymus renders it difficult to establish this relationship on other than a purely clinical basis. Even as matters stand it may be regarded as proved that in subjects of enlarged thymus the use of a general anæsthetic should, whenever possible, be avoided, but, as it is practically impossible to ascertain beforehand that this gland is enlarged, we are fain to fall back on the presence of hypertrophied follicles at the base of the tongue and enlargement of the spleen as constituting contra-indications for the administration of an anæsthetic.

The Quackery of Rheumatism.

A sufferer from chronic rheumatism, to whom east winds and wet weather brought nothing but torture, has been giving some journalists an account of the many disappointments he suffered when trusting vaunted remedies. His list includes the names of 1,437 remedies, one and all of which he fairly tested during his life of torture. Many of them still make a noise in the public ear. For years he wrapped himself in red flannel; to this he added wearing flowers of sulphur in his stockings; as an additional precaution he carried a few cut potatoes in his pockets and afterwards supplanted them with a slice of raw onion. Early in the morning he drank a pint of good ale to which a rusty nail had been added at bedtime. For this rather agreeable medicine he substituted successively Glauber salts, in hot water, Epsom salts, and a long series of natural, purgative, and other medicinal waters. He then took to wearing a hare's foot round his neck and commenced a systematic course of patent and proprietary pills. We will not, however, inflict an enumeration of the many varieties of medication this victim of rheumatism tried; we will merely add that he is still a sufferer and still seeks relief from every advertised nostrum.

The Council Election of the Royal College of Surgeons of England.

The election of four members of the Council of the Royal College of Surgeons of England took place on the 3rd inst., with the result that the following gentlemen were elected:—Mr. Howard Marsh, Mr. J. H. Morgan, Mr. H. H. Clutton and Mr. C. W. Mansell Moulin. The unsuccessful candidates, in numerical order, were Mr. Jordan Lloyd, Mr. J. Bland Sutton, Sir W. H. Bennett and Mr. Clinton T. Dent.

The International Congress on the Welfare and Protection of Children will be held in the Guildhall, London, on Tuesday, July 15th, and three following days, under the presidency of Earl Beauchamp. The medical section will be presided over by Sir James Crichton Browne, F.R.S., M.D., who is expected to deal with the question of "Tuberculosis" in his opening address.

The annual meeting of the North-East London Clinical Society was held on Thursday, July 3rd, at the Tottenham Hospital, and afterwards a garden party took place in the extensive and beautiful grounds of the hospital.

The last meeting of the British Child Study Association took place on June 24th, at Normansfield, Hampton Wick, where members and visitors were the guests of Dr. and Mrs. Percival Langdon-Down.

The annual meeting and dinner of the Brussels Medical Graduates' Association will be held in London on Tuesday next, July 15th, at 7.30 p.m., at the Trocadero Restaurant.

The authorities of St. Thomas's Hospital are to be congratulated on their windfall of over a quarter of a million, which comes to them under the will of the late Mr. Charles Gassiot.

The Queen will open the Imperial Coronation Bazaar in aid of the Children's Hospital, Great Ormond Street, Bloomsbury, at the Botanical Gardens on Thursday, July 10th.

PERSONAL.

Dr. P. Murison has been appointed Medical Officer of Health for Durban.

Mr. Richard W. Lloyd has been elected president of the West London Medico-Chirurgical Society, vice Sir Alfred Cooper, whose term of office has expired.

Mr. Shaw McLaren, Assistant Surgeon to the Royal Infirmary, Edinburgh, has resigned his post, and is about to take up medical missionary work in India.

A portrait of the late Dr. D. J. Leech, Professor of Materia Medica and Pharmacology in the Victoria University, Manchester, has been presented to the Manchester Royal Infirmary.

The Duke of Devonshire, President of the Board of Education, will preside at the opening of the Nature Study Exhibition, Royal Botanic Gardens, Regent's Park, by the Duchess of Devonshire, at 3 p.m., on Wednesday, July 23rd.

Sir Henry F. Norbury, M.D., K.C.B., Director-General of the Medical Department of the Royal Navy, will preside at the distribution of prizes to the successful students of St. Thomas's Hospital to-morrow (Thursday) at 3 p.m. Sir Henry, we may recall, has just been appointed Honorary Surgeon to the King.

Dr. Malcolm M. Sinclair, resident medical superintendent of the Cotswold Sanatorium, Gloucestershire, has been appointed medical superintendent of a large new sanatorium being built at the Blue Mountains, near Sydney, New South Wales. Candidates for this important appointment hailed from Australia, United States, and Germany, as well as from the United Kingdom.

A Medical Libel Action.

Dr. W. H. Bathurst, of Walthamstow, has accepted £50 and costs in settlement of a claim for damages for libel, uttered by a fellow member of the Walthamstow District Council, imputing improper conduct to him.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

CHLOROFORM AS A NARCOTIC.

To the Editor of The Medical Press and Circular.

Sir,—I have often read of persons inhaling chloroform in order to combat insomnia, and the point has often been raised whether it be possible to induce unconsciousness by means of chloroform in persons actually asleep. Under these circumstances it occurs to me that a little experiment of my own may not be without interest. I was suffering recently from a particularly exasperating form of sleeplessness and, as the night was too far advanced to take any of the usual hypnotics, I fetched the chloroform and tried to send myself to sleep, taking all necessary precautions to avoid an overdose. It, of course, produced a sensation of calm after the initial disagreeable feeling of impending asphyxia, but nothing at all akin to genuine sleep, and when the effects had passed off I was as wakeful as before. I repeated the experiment several times, but always with the same result. I infer that unless the quantity of chloroform inhaled be such as to determine a certain degree of permanent stupor it is in no sense a hypnotic.

Incidentally I made the comparison between inhaling a few drops—about half a drachm—of chloroform from a mask and inhaling the drug from a Junker's inhaler (Krohne's modification). With the mask the first few inspirations were oppressively pungent and asphyxiating, and throughout the effect on the respiratory tract was distinctly disagreeable. With the inhaler, on the other hand, no effect of the kind was produced, and no discomfort of any kind resulted. I noted, too, that the amount of chloroform required to produce unconsciousness was less than a fourth part of that used on the mask, a fact which no doubt explains the difference in the nature of the resulting impression.

Quite apart from the greater safety claimed for anæsthesia induced by a regulating inhaler, my own sensations have satisfied me that it is "cruelty to animals" to use the mask with its attendant drawbacks, when it is possible to obtain positively satisfactory results with the inhaler, and I am more surprised than before that the manipulation of an inhaler does not form part of the routine instruction given to students at the medical schools in the matter of the administration of anæsthetics.

I am, Sir, yours truly,
Practitioner.

Obituary.

ALEXANDER MARSDEN, M.D.St.And., F.R.C.S.Ed.

The death is announced of Dr. Alexander Marsden, Chairman of the General Committee of the Cancer Hospital, Brompton Road. Dr. Marsden, whose career was long and active, was originally in the Army Medical Service, in which capacity he served at the General Hospital, Scutari, with Miss Nightingale, and subsequently at the siege of Sebastopol. He early took an interest in the treatment of cancer, and founded the Cancer Hospital, in Brompton Road, with which, as surgeon and chairman of committee, he has ever since been connected. He also assisted in founding the Royal Free Hospital, in Gray's Inn Road, of which he was trustee. Dr. Marsden was the author of numerous contributions and works on cancer, which embodied the varying views from time to time obtained in reference to its nature and treatment, but for the last quarter of a century he limited himself to administrative work.

A Remarkable Baby.

This is the season for big gooseberries—and big babies. The last to hand is the birth of a sixteen pound baby, and one can only regret that "it" was born as far away as St. Louis, Missouri.

Literature.

LIMBECK ON THE CLINICAL PATHOLOGY OF THE BLOOD. (*a*)

Professor von Limbeck's work on the clinical pathology of the blood first appeared about ten years ago, and the second edition, which has been translated into English by Drs. Latham and Nachbar, is now published by the New Sydenham Society.

It is mainly an epitome of the more important observations that have been made by others, with the addition, in most cases, of the author's experiences on the different points discussed.

The methods of investigation described are very numerous. Five methods are given for determining the volume of the blood, but not one of them has the smallest claim to be considered accurate. Six hæmocytometers are described, as are eight instruments for hæmoglobin estimation. Of the latter instruments, the author considers the hæmoglobinometers of Gowers and Fleischl are preferable, as being simpler as well as more free from error. A brief description is given of the methods of investigating the histological characters of the blood as well as its physical and chemical characters The morphology of the blood is dealt with sufficiently fully, and a short account of the parasities of the blood (chiefly those of the malarial fevers) is given.

The last chapter is devoted to the results of clinical investigations of the changes in the blood in the primary and secondary anæmias, leukæmia, and in other pathological conditions, while there is a short appendix on the anæmias of childhood. The book furnishes as far as its size permits a good account of the work that has been done in hæmatology. It would have been rendered more useful, however, by the addition of a few illustrations of the histology of normal and abnormal bloods.

There is an extremely full and valuable bibliography, and a good index. The work of the translators is to be commended.

Medical News.

FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

The programme for the XIVth International Congress of Medicine to be held in Madrid, Spain, in April, 1903, is already published. The following is a translation of the principal regulations:—

1. The Congress will be under the patronage of his Majesty the King, Don Alphonso XIII., and of the Queen Mother, during its sitting, from April 23rd to 30th, 1903.

2. The Congress will consist of members of the medical profession, dentists, veterinarians and pharmaciens, who having complied with the usual regulations are free to take part in all the meetings, either by reading a paper or by oral comments.

3. Members are also entitled to a copy of the "Proceedings," and can obtain extra copies at a fixed price. Subscriptions for extra copies will be received by the general secretary at the close of the Congress.

4. The papers read shall remain with the secretaries of the sections for publication.

The Congress shall be composed of the following sections:—(*a*) Anatomy: Anthropology, comparative anatomy, embryology, anatomy descriptive, histology, serathology. (*b*) Physiology: Physical and chemical. (*c*) Pathology: Pathological anatomy, bacteriology. (*d*) Therapeutics: Therapeutics, hydrology, pharmacy. (*e*) Pathology internal. (*f*) Neuropathy: Mental maladies, cranial anthropology. (*g*) Pediatrics. (*h*) Dermatology and syphilography. (*i*) Surgery: Surgery and operative surgery, urinology. (*j*) Ophthalmology. (*k*) Oto-rhino laryngology: Otology, rhino-laryngology. (*l*) Odontology and otomatology. (*m*) Obstetrics and gynæcology. (*n*) Medicine and hygiene, military and naval. (*o*) Hygiene, epidemiology, and sanitary science. (*p*) Legal medicine and toxicology.

6. Members should notify the section they wish to attend on registering their name with the secretary.

7. A committee, consisting of the president, general secretary, treasurer, and some others, shall regulate the course of business of the Congress. The opening and closing meetings shall be general, and only those invited to address the meeting are expected to do so.

8. At the opening meeting the general secretary shall state the arrangements made, the President will deliver his inaugural address, and the honorary presidents will be appointed.

9. Committees of sections are expected to arrange their papers and so forth, and appoint suitable abstract writers for each language, to facilitate discussion.

10. The reading of a paper is not to exceed fifteen minutes, and in discussion no speaker is to exceed five minutes. The reply of an author to criticism is confined to ten minutes.

12. The titles of all communications are to be with the Secretary-General by January 1st, 1903, together with the conclusions he arrives at, and a short abstract of his paper, which latter will be printed and distributed to the members of the section in which it is to be read.

12. The official languages of the Congress are Spanish, French, English, German and Italian. Ladies, who are relatives of the members, and who accompany them, will have a special reduction in their train fares and obtain a ticket for the Congress meetings for twelve pesetas each.

Society for the Study of Diseases in Children.

This Society held their provincial meeting at Manchester on Saturday, June 21st. Cases were demonstrated in the wards of the Children's Hospital, Pendlebury, by the honorary medical staff prior to the meeting which took place at four o'clock, and which was well attended. Dr. Henry Ashby was in the chair, and at its conclusion a hearty vote of thanks was proposed to the chairman and the hospital authorities. Many London representatives and provincial members were present. A report of proceedings will be found in another column. Subsequently dinner was served at the Queen's Hotel, Manchester, Dr. A. E. Sansom presiding, which was well patronised and passed off successfully. The following day the members and their friends enjoyed a trip into Derbyshire. After a country drive from Grindelford, luncheon awaited the party at the "Peacock," Baslow, where they also partook of tea after a visit to Chatsworth, and they were subsequently driven to Bakewell Station in time for the evening train for London, and for that for Manchester and Liverpool. The provincial meeting next year will take place at Brighton. The annual general meeting will be held at the Hotel Cecil at 6.30 p.m. on Wednesday, July 16th, and will be followed by dinner at 7.30 p.m., at which guests will be welcomed. Dr. Henry Ashby will be in the chair.

A Valuable Find.

A specimen of the mammoth has recently been found near the River Ebrosowka, in Eastern Siberia, by Dr. Hertz. The body has been found in a good state of preservation, embedded in ice. The hair is of a reddish-brown colour. Undigested food was found in the stomach of the animal, and on its tongue was the herbage which it ate on the day of its death. The specimen is almost as perfect as the notable 1846 one, which was so marvellously preserved that the stomach still showed young shoots of fir and pine. It differs from other finds in that it occupied a peculiar reclining position with its legs bent under its body, and was not in the upright position like those which were buried by sinking into the tundra marsh.

Royal College of Surgeons of England.

The Council of the College give notice that they will proceed on the 31st inst. to elect an Examiner in Surgery in the vacancy caused by the expiration of the period of office held by Mr. C. H. Golding-Bird, F.R.C.S

(*a*) "The Clinical Pathology of the Blood." By Dr. Rud. R. v. Limbeck. Translated from Second German Edition. London: The New Sydenham Society. Mr. K. H. Lewis, Agent.

who is, however, a candidate for re-election. At the same meeting an Examiner in Dental Surgery will also be elected in the vacancy caused by the resignation of Mr. Morton Smale. Applications must be lodged with the Secretary before the 23rd inst.

Dublin University-Conferring Degrees.

THE following degrees were confered on July 1st:—

In Absentia.

Licentiatus in Medicina, in Chirurgia, et in Arte Obstetricia.—Georgius Ricardus Harman.

Baccalaurei in Medicina.—Guilelmus Hall Peile, Guilelmus Taylor, Herbertus Leslie Thurnell.

Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.—Robertus Pounden Beatty, Carolus Molyneux Benson, Wallace Benson, Ernestus Brabazon Booth, Guilelmus Joseph Butler Bourke, Guilelmus Ashley Graves Cluffe, Joseph Ricardus Garratt, Harry Ffrench Johns, Johannes Swift Joly (B.Ch. Stip. Cond.), Herbertus Guilelmus Jones, Georgius Henricus Keene, Robertus Houston MacNicol, Guilelmus Franciscus Alexander Moyers, Rev. Franciscus Mullen, Jacobus Crossle Scott, Ricardus Franciscus Steele, Robertus Georgius Hetherington Tate, Johannes Archibaldus Valentine, Carolus Waltham Webb, Johannes Stevenson Wilson, Herbert Francis Perkins.

Doctores in Medicina.—Carolus Arturus Kinahan Ball, Guilelmus Joseph Butler Bourke, Guilelmus Ashley Graves Cluffe, St. George Eyre Harris, Franciscus Jacobus Strong Heaney, Harry Ffrench Johns, Johannes Swift Joly, Guilelmus Grierson Joynt, Jacobus Milne, Guilelmus Franciscus Alexander Moyers, Thomas Guilelmus Moorhead (stip. cond), Ricardus Guilelmus Mullock, Johannes Joseph Power, Carolus Vivian Beresford Stanley, Guilelmus Clegg Stevenson, Herbertus Leslie Thurnell, Johannes Archibaldus Valentine.

In Absentia.—Baccalaureus in Medicina et in Chirurgia.—Eduardus Cuthbert Nangle (Autea Liceat.)

St. Thomas's Hospital, Medical School.

SIR HY. F. NORBURY, M.D., K.C.B., Director-General of the Royal Navy Medical Department, will distribute the prizes at this school to-morrow (Thursday). Among the principal prize-winners for the winter session, 1901-2, are the following:—

H. B. Whitehouse, of Birmingham, Entrance Science Scholarship, £150.

G. R. Footner, of Romsey, University Scholarship, £50.

First Year Students.—H. B. Whitehouse, of Birmingham, the Wm. Tite Scholarship, £27 10s.; R. F. Hebbert, of Guildford, College Prize, £20; W. R. Bristow, of Bexley Heath, College Prize, £10.

Second Year's Students.—L. E. C. Norbury, of Ealing, the Peacock Scholarship, £38 10s.; G. J. Langley, of East Dulwich, College Prize, £20; A. W. Hooker, of Putney, College Prize, £10.

Third Year's Students.—H. A. Kisch, of Maida Vale, Second Tenure of Musgrove Scholarship.

Fifth Year's Students.—C. U. Ind, of Margate, College Prize, £10 (Medicine); W. H. Harwood-Yarred, of Brixton, College Prize, £10 (Surgery); G. D. Franklin, of Leicester, College Prize, £10 (Midwifery); G. D. Franklin, of Leicester, Hadden Prize, £10 (Pathology); W. H. Harwood-Yarred, of Brixton, College Prize, £10 (Pharmacology); A. D. Hamilton, of Chester, College Prize, £10 (Forensic Medicine and Insanity); W. H. Harwood-Yarrow, of Brixton, College Prize, £10 (Public Health).

The following are the recipients of medals:—Practical Medicine: G. D. Franklin, of Leicester, the Mead Medal; H. O. Butler, of Shanghai, and C. H. Sedgwick, of Grove Park (equal), the Wainwright Prize. Surgery and Surgical Anatomy: W. H. Harwood-Yarred, of Brixton, the Cheselden Medal. Pathology and Morbid Anatomy: W. M. G. Glanville, of Bristol, the Bristowe Medal. For General Proficiency and Good Conduct: W. H. Harwood-Yarred, of Brixton, the Treasurer's Gold Medal.

Rontgen Society.

AT the annual meeting held on Thursday last, July 3rd, Mr. Herbert Jackson, F.C.S., was elected President.

The following were chosen as Vice-Presidents:—The Right Hon. Lord Blythswood, J.P., D.L., LL.D., F.R.A.S.; the Right Hon. the Earl of Crawford, K.T., F.R.S.; J. Mackenzie Davidson, M.B.; D. Ferrier, M.D., F.R.S.; J. H. Gladstone, D.Sc., F.R.S., F.C.S.; Dawson Turner, M.D., of Edinburgh.

Council: G. B. Batten, M.D., C.M., Barry Blacker, M.D., B.S., Wm. Chattaway, J. H. Gardiner, F.C.S., A. W. Isenthal, F.R.P.S., Rev. P. Mulholland, B.A., E. Payne, M.A., C. E. S. Phillips, G. H. Rodman, M.D., E. W. H. Shenton, L.R.C.P., M.R.C.S. (Librarian and Curator), H. Snowden Ward, F.R.P.S., J. Wimshurst, F.R.S.

Hon. Treasurer: J. J. Vezey, F.R.M.S.

Hon. Secretary: F. Harrison Low, M.B.

Death under Chloroform.

A MAN, age 55, died at the Salisbury Infirmary last week after inhaling 120 minims of chloroform, given preparatory to the wiring of a fractured humerus. Death was attributed to paralysis of the centre of respiration, and nothing was found post-mortem to explain his susceptibility to the drug.

Robes for Pharmacists.

IT is reported that at the recent congress of Austrian pharmacists in Vienna it was decided to adopt a long robe as the professional garb, the robe to be worn during business hours by chemists and their assistants. It will also serve as a *robe de chambre* and as a *peignoir*, and in winter nights to supplement any shortcomings in the bed clothes—all this in addition to "raising the prestige of the pharmaceutical profession."

A Doubtful Pox.

MR. D. G. KENNEDY, of Bermondsey, was summoned last week for failing to notify a case of chicken-pox. It transpired that he had filled in the certificate—"pox"—intending no doubt to convey the idea that he was not sure which, whether it was chicken or small-pox and from this attitude he declined to depart, hence the proceedings. In the upshot, Mr. Kennedy undertook to fill up the forms in future to the best of his judgment and thereupon the case was dismissed. Of course, this is very funny, but we question the propriety of causing all this trouble when it is so easy to be humorous, and to show it in simpler fashion.

The Oxygen Hospital.

THE sixth annual report of the Oxygen Hospital testifies to its continued and unimpaired vitality. It is not suggested that the results are to be measured by numbers, since these are necessarily small, but rather by what may be termed case-success. Of ninety-six cases seventy have been discharged—we trust in good health, though this is not explicitly stated. The results of the application of oxygen in lupus, after scraping, certainly seem to have been very encouraging, a large proportion having remained free from recurrence for several years. The ozone treatment of middle-ear deafness is claimed to have been uniformly successful, but in the absence of more precise data we must reserve our opinion. The "cubicle" treatment of consumption by inhalation of air fortified by admixture with oxygen is said to have produced "remarkable" results, but here again the data are insufficient to justify a definite opinion. In any event the experiments and observations which are under way at the hospital are very interesting and may conceivably result in establishing the exact therapeutical position of oxygen.

An Epileptic Colony.

A GARDEN party will be given at the Epileptic Colony at Chalfont St. Peter, Bucks, to-day (Wednesday), when visitors will be afforded an opportunity of seeing the colonists engaged in their work upon the farm, in the workshops, and in the laundry.

The Medical Intercession Service.

A SERVICE of intercession for the King was organised by the Guild of St. Luke, and took place at St. Paul's Cathedral on Wednesday last, when upwards of 400 medical men attended, most of them wearing their university robes. At the conclusion of the service the following message was dispatched to the Queen· "The

Guild of St. Luke, associated with many members of the medical profession, having assembled in St. Paul's Cathedral this evening to offer an intercessory service to Almighty God on behalf of his Majesty the King in his sickness, beg leave to present their humble duty to your Majesty and to express their fervent wishes for his Majesty's speedy and complete recovery."

Small-pox in London.

The epidemic of small-pox in the Metropolis is steadily declining, the number of admissions on one day having fallen to three. The number of patients still under treatment in the hospitals of the Metropolitan Asylums Board has fallen to 722. It is pointed out that the public should bear in mind the fact that this decline is only seasonal, and affords no protection against a recrudescence as soon as colder weather supervenes.

West London Medico-Chirurgical Society.

At the annual meeting of this Society, held on Friday last, July 4th, the following officers and members of Council for 1902-3 were elected:—President—Mr. R. W. Lloyd (*a*). Vice-Presidents—Mr. W. McAdam Eccles, Mr. Horace Walker, Dr. S. A. Bontor, Mr. F. Savery, Mr. G. E. Twynam (*a*), Mr. H. W. Chambers (*a*), Mr. W. P. Mallam (*a*), Dr. W. T. Gardner (*a*). Council—Mr. T. R. Atkinson, Dr. A. Baldock, Mr. L. A. Bidwell, Dr. E. F. Potter, Dr. G. P. Shuter, Dr. Seymour Taylor, Mr. R. Pollock (*a*), Dr. Leonard Dobson (*a*), Dr. A. M. Ross Sinclair (*a*), Dr. A. Whitfield (*a*), Mr. G. A. Simpson (*a*), Mr. J. G. Pardoe (*a*). Treasurer—Mr. T. Gunton Alderton. Secretaries—Dr. E. A. Saunders, Dr. C. Buttar (*a*). Librarian—Mr. C. B. Keetley. Editor of Journal—Mr. H. Percy Dunn. Editorial Secretary of Journal—Mr. W. McAdam Eccles. (*a*) Did not hold similar office last year.

Royal College of Surgeons in Ireland.

The following candidates have passed the primary part of the Fellowship Examination:—G. P. A. Bracken, J. J. Conolly, A. N. Crawford, C. A. Cusack, R. W. D. Leslie, T. C. C. Leslie, W. F. B. Loughnan, J. C. Murphy, I. Pratt, and I. S. Sheild.

Dublin Sanitary Association.

At a meeting of the Dublin Sanitary Association held last week, it was pointed out that while the death-rate in the city continues low, there is at present a widespread and increasing epidemic of measles in the Dublin registration area. 191 cases of this disease were notified in the city during the week ending June 28th, while twenty-six cases were notified in the Pembroke Urban District during the same period. The Council note with regret that no information as to the prevalence of measles in the Rathmines Urban District is furnished in the Registrar-General's returns, the disease not being notifiable in the Rathmines district. The following resolution was passed unanimously:—"Resolved—To call the attention of the Urban Sanitary authority of Rathmines to the necessity of adding measles to the list of infectious diseases notifiable in that district, owing to the existence of a widespread and rapidly increasing epidemic of that disease in the Dublin registration area."

Vaccination in Dockyards.

An Admiralty Order issued at Chatham Dockyard directs that] for the future men entered in the yard shall be taken on conditionally on their being revaccinated, unless they can prove that they have recently been vaccinated.

Munificent Legacy to St. Thomas's Hospital.

The late Mr. Charles Gassiot has bequeathed the residue of his estate to be held in trust for St. Thomas's Hospital, and it is estimated that this will amount to about a quarter of a million sterling.

Pass Lists.

Royal College of Surgeons, Edinburgh.—The Fellowship.

At a meeting of the College, held July 2nd, the following gentlemen, having passed the necessary examinations, were admitted Fellows of the College:—John Broadley, M.B.; Charles John Caddick, M.B., C.M.; David Robertson Dobie, M.D.; Robert Edwin Goone-Tilleke, L.R.C.S.E.; Henry McIlree W. Gray, M.B., C.M.; Abraham Haynes, L.R.C.S.E.; Guy Bertram Hollings, M.D., M.R.C.S.Eng.; Albert Henry B. Kirkman, M.R.C.S.Eng.; Francis Lionel Provis, M.R.C.S. Eng.; Matthew Carrington Sykes, M.R.C.S.Eng.; and Gangakanta Nag, L.R.C.S.E.

Society of Apothecaries of London.

The following candidates passed in the Primary Examination (Part I.) on July 2nd and 3rd, 1902:—

Biology.—L. W. Bradshaw.

Chemistry.—F. M. Cunningham, C. A. Mortlock-Brown, C. E. Pring.

Materia Medica and Pharmacy.—H. F. Briggs, J. M. Burke, W. H. A. Elliott, A. R. McEnnery.

The following candidates passed the Preliminary Examination (Part II.)—

Anatomy.—H. H. R. Bayley, E. H. G. Duncan, W. H. A. Elliott, W. F. H. Ives, G. B. Messenger, N. H. Oliver, E. D. Richardson, G. Rollason, C. A. Sampson, I. T. Walker.

Physiology.—H. H. R. Bayley, E. H. G. Duncan, W. H. A. Elliott, A. G. Gamble, G. Heathcote, W. S. Hughes, W. F. H. Ives, H. M. Langdale, E. Moir, N. H. Oliver, E. D. Richardson, G. Rollason, C. A. Sampson, I. T. Walker, R. M. Wingent.

University of Dublin (Trinity College).

Previous Medical Examination.

The following candidates passed the Examination in Anatomy and Institutes of Medicine during Trinity Term. Names arranged in order of merit:—William J. Powell, Montgomery Du B. Ferguson, George Mac G. Millar, John A. Pringle, Howard English, Wilfrid T. Thunder, Benjamin Johnson; Henry E. M'Cready and George E. Nesbitt (equal), Thomas Creaser, Carlile Kelly, Joseph E. Houstin, Charles R. Coppinger, Robert Magill, Vincent Mayne, Francis J. S. Crean, Charles R. Morris; John W. Burns and Thomas Wilson (equal); Cecil Boyd, Geoffrey Friel, and William Hassard (equal).

Physics and Chemistry.—Frank R. Seymour, Francis R. Coppinger; Edward O. Marks and John D. Sands (equal), Thomas J. Cobbe, Ralph S. Oldham; Theodore C. Somerville, John W. Tomb, and Henry D. Woodroffe (equal), Samuel G. S. Haughton, Gustav W. Thompson, Richard Connell, Cecil Conyngham; John C. P. Beatty and Henry J. Keane (equal); Reginald Holmes and Robert B. Jackson (equal); James E. Mac Farlane and George E. G. Vickery (equal), Basil Brooke, George B. M'Caul, Thomas L. de Courcey, Edward Gibbon, Howard S. Millar; Henry D. Drennan and Thomas H. Peyton (equal), Ernest C. Phelan.

Botany and Zoology.—Walter G. M. Anderson, Edward C. Stoney; Thomas J. Cobbe and Robert E. Wright (equal); Alfred G. Alexander and Charles T. Atkinson (equal); Francis A. Coppinger, Alexander L. Otway, Crosbie Maurice B. Talbot; John C. P. Beatty and Rev. Thomas Brook (equal), John W. Tomb, Thomas H. Peyton, George E. G. Vickery and Reginald Holmes (equal); Edwin B. Bate and Harry Ff. Johns (equal); William Nicholson and Dudley F. Torrens (equal); Thomas M. Crawford and Charles G. Sherlock (equal).

The following passed the Final Examination (Section B):—Thomas H. Gibbon; William R. P. M'Neight and Seaton S. Pringle (equal); Alexander H. Marks and John H. Torney (equal), Robert J. Fleming; Anthony H. Corley and Reginald H. Lee (equal), Thomas W. Crowley, Charles A. Stone, David C. Pearson, Maurice FitzGibbon.

Surgical Travelling Prize.—Charles A. K. Ball.

Special Prize.—Richard A. Stoney.

Medical Scholarships.

In Anatomy and Institutes of Medicine.—James G. Wallis (Trinity College Scholarship), John Cunningham (Stewart Scholarship).

In Physics, Chemistry, Botany and Zoology.—Francis O. B. Ellison.

Purser Medal in Institutes of Medicine.—William J. Powell.

Diploma in Public Health, Part I.—Francis W. Lamb.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or nitials*, and avoid the practice of signing themselves "Reader," Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. S. V.—Very possibly there exists some error of refraction to account for the "eye strain," especially as local treatment has failed to relieve. You should have this attended to.

Mr. J. Hunns (Wood Green).—Your communication was received as we were "at Press."

A GIGANTIC SOCIETY.

On the established principle that "all great things from small do grow," we have now before us the Fifty-first Annual Report of "The Birkbeck," which is probably the most colossal institution of its kind in the world. Fifty years ago its annual receipts were £25,000; last year they were 90 millions sterling, and during its fifty years' existence nearly 309 millions have passed into its coffers. It began as a small building society, and is now, by judicious management, the largest of its class, and a bank in the first rank as well. We are glad to know that many medical men are among its members, and we congratulate them on their good fortune.

G. S. A.—You could hardly do otherwise than return the cheque. There may be nothing illegal or "illicit" in the transaction, but it would be in the last degree objectionable.

Electro.—(1) If you will let us have a precise statement of the facts of the case we will see what can be done. (2) If you wish an analysis made it must be at your own expense.

HOW TO ACQUIRE A GOOD FIGURE!

According to a lady's journal the best means of acquiring a good figure is "To eat black grapes, drink cocoa, not tea, and take cod-liver oil daily." Simplicity is bliss!

Westland B.—The matter having gone so far, the advice of a trustworthy solicitor should be sought.

Dr. G. B. (Bristol).—Chinosol of the strength of 1 in 4,000 is the best antiseptic for use in ocular surgery.

Editor of the "Baker."—See reply to Mr. Hunns.

Dr. C. S.—The Coronation Honours were dealt with fully in our last; the other matter also has now passed beyond necessity of record.

Meetings of the Societies, &c.

LONDON.

Wednesday, July 9th.

Dermatological Society of London (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

Thursday, July 10th.

British Gynæcological Society (20, Hanover, Square, W.).—8 p.m. Specimens will be shown by Mr. Jessett, Dr. Hodgson, Dr. Purcell, and others. Papers: Mr. B. Jessett and Dr. H. Hodgson.

Friday, July 11th.

British Laryngological, Rhinological, and Otological Association (11, Chandos Street, Cavendish Square, W.).—4 p.m. Dr. Macintyre, President. Cases and specimens will be shown and papers read by Mr. Lennox Browne, Dr. Wyatt Wingrave, Dr. Abercrombie, and others.

Tuesday, July 15th.

Society for the Study of Inebriety.—The Quarterly Meeting will be held at the London Temperance Hospital, Hampstead Road, at 4 p.m. Dr. Robert Jones will read a paper on "Mental Dissolution, the Result of Alcohol." Visitors are earnestly invited to be present, and to join in the discussion.

Appointmen

Blamey, J., M.R.C.S.Eng., L.S.A., Medical Officer of Perranwell.

Collier, James, M.D., M.R.C.P.Lond., Assistant Physician to the National Hospital, Queen Square, W.C.

Elliott, G. C., M.B., C.M.Edin., House Surgeon to the Staffordshire General Infirmary.

Hawthorne, C. O., M.D.Glasg., M.R.C.P.Lond., Lecturer on Forensic Medicine in the London School of Medicine for Women.

Horton, Thomas, M.D., B.S.Durh., L.R.C.P.Lond., M.R.C.S., Honorary Surgeon to the Torbay Hospital, Torquay.

Jeffeeriss, Iain, M.R.C.S.Eng., L.R.C.P.Lond., First Assistant Medical Officer to the Hendon Sick Asylum.

King, John, M.R.C.S., L.R.C.P.Ed., J.P., Medical Officer of Health for Stratton and Bude (Cornwall).

Lister, Thos. D., M.D., M.R.C.P.Lond., Assistant Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood.

Male, Herbert C., M.D.Edin., Honorary Medical Officer to the Croydon General Hospital.

O'Brien, M. J., L.R.C.P., L.R C.S.I., Certifying Surgeon under the Factory Act for the Mountmellick District of Queen's County.

Phillips, Mary E., M.B.Lond., Second Assistant Medical Officer at the London Sick Asylum at Hendon.

Stock, W. S. V., M.B., B.S.Lond., Resident Medical Officer to the Royal Infirmary, Manchester.

Thyne, Thomas, M.D.Edin.. Medical Officer for the Mill Corner and Cockfosters District of Enfield Parish.

Wright, Hugh P., M.B., Ch.B.Glasg., House Surgeon to Teignmouth Hospital, South Devon.

Vacancies.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Clerk's Offices, 45, Hamilton Square, Birkenhead.

Borough Asylum, Portsmouth.—Wanted at once Assistant Medical Officer. Salary £140 per annum, with board, lodging, &c. Applications to the Medical Superintendent.

Brighton, Hove, and Preston Dispensary.—Two House Surgeons. Salary £160 per annum, with coals, gas, apartments, washing, and attendance. Applications to the Assistant Secretary, 113, Queen's Road, Brighton.

Bristol Royal Hospital for Sick Children and Women.—House Surgeon. Salary £120 per annum, with rooms and attendance. Applications to the Secretary.

Burnley Union.—Resident Assistant Medical Officer for their Workhouse, Burnley. Salary £120 per annum, with furnished apartments, rations, washing, and attendance. Applications to J. S. Horn, Clerk to the Guardians, Union Offices, Burnley.

Chichester Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to A. J. Marshall, Secretary.

City Hospital for Infectious Diseases, Newcastle-upon-Tyne.—Resident Medical Officer. Salary £100 per annum, with board, lodging, &c. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

East London Hospital for Children and Dispensary for Women, Glamis Road, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Luncheon is provided at the hospital. Applications to Thomas Hayes, Secretary.

Lanark County Council.—Assistant Medical Officer of Health. Salary £140 per annum, with travelling expenses. Applications to the County Medical Officer, Hamilton, N.B.

Manchester Children's Hospital, Pendlebury.—Medical Officer. Salary £180 per annum. Applications immediately to the Secretary, Children's Dispensary, Garside Street, Manchester.

Mercer's Hospital, Dublin.—Resident Medical Officer. Immediate application to John Robinson, Registrar (see advt.).

Newport and Monmouthshire Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary.

New Ross Union.—Medical Officer. Salary £100 per annum, together with usual Vaccination Fees, also £15 per annum as Medical Officer of Health. Immediate application to P. A. Pope, Clerk of the Union (see advt.).

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Also one Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel are found for the above surgeons. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Parish of St. Leonard, Shoreditch.—Resident Assistant Medical Officer. Salary £150 per annum, with rations furnished apartments, and washing in the Infirmary. Applications immediately to Robert Clay, Clerk to the Guardians, Clerk's Office, 213, Kingsland Road, N.E.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, fuel, lighting, and washing. Applications immediately to the Medical Superintendent.

Births.

Greenwood.—On July 2nd, at Corby, Grantham, the wife of A. C. Greenwood, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

Booker—May.—On July 5th, at St. Mary's, Kelvedon, Essex, Charles William Booker, F.R.C.S.Edin., of Witley, Surrey, younger son of Fredk. Booker, of Blackheath, Kent, to Ada Constance, third daughter of the late George May, Tiptree Hall, and of Kelvedon.

Butler—Greenbank.—On July 2nd, at St. Peter's, Ealing, Hedley Ormonde Butler, B.A., M.B.Camb., eldest son of George Butler, of Shanghai, to Louise Alice, only daughter of Henry Greenbank, Ealing.

Fraser—Reynolds.—On July 2nd, at Christ Church, Leeson Park, Dublin, Alec Fraser, M.B.Lond., of Cambridge, second son of Alexander Fraser, Esq., of Blackheath, to Marian, only daughter of Professor Emerson Reynolds, D.Sc., F.R.S., of Dublin.

Mitchell—Hibbert.—On July 3rd, at Holy Trinity Church, Guildford, Arthur Martin Mitchell, M.A., M.D., B.C., D.P.H. Cantab., youngest son of the late Rev. Walter Mitchell, M.A., vicar of Purton, Wilts, to Mary Evelyn, eldest daughter of the late Francis Henry Hibbert, I.C.S., Guildford.

Deaths.

Bond.—On July 1st, at the London Fever Hospital, of scarlet fever, after a few days' illness, Edmund De la Fosse Bond, M.A., M.B. Oxon., M.R.C.S., resident house surgeon of St. George's Hospital, youngest son of the late Revd. Fredk. H. Bond, M.A., formerly of Marlborough, in the 29th year of his age.

Marsden.—On July 2nd, suddenly, at 92, Nightingale Lane, Wandsworth Common, Alexander Marsden, M.D., F.R.C.S.E., aged 69 years.

Vienna Clinical Lecture.

PALATAL PARALYSIS.

By DR. S. ERBEN,
Assistant Professor at the University of Vienna.

[*Specially Translated for* THE MEDICAL PRESS AND CIRCULAR.]

THE following case of paralysis of the palate will best illustrate the care necessary for the diagnosis of paralysis in the neighbourhood of the buccal cavity. The patient was a grocer's assistant, æt. 27, who had enjoyed perfect health till three weeks previously, when he was attacked with fever and general prostration. Ten days later he had so far recovered that he could return to work. About a fortnight after this he observed that he could not swallow as well as he usually did, every effort to swallow being followed by regurgitation through the nose or flowing back into the mouth. There was no hoarseness or cough, and the tongue and lips were intact, while speech was perfect. The mucous membrane of the throat and mouth was pale, no inflammation to be observed anywhere, while the tonsils were barely visible. Nowhere was there any white deposit. There was no adenoid growth on the posterior surface of the fauces, but it was observed that the uvula was asymmetric, as both the palato-glossal and the palato-pharyngeal arches were to be seen distinctly deviated to the left side, while nothing but the anterior arch could be seen on the right as the former quite covered the latter. When at rest the arches of the palate were seen as in Figure I., but when phonation was performed the appearance was as in Figure II., which showed the healthy muscles of the right side dragging the uvula to that side.

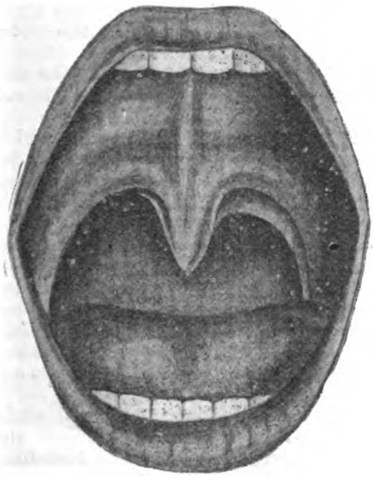

FIG. I.

From this asymmetry it was clear that unilateral paralysis of the palate was present; the drooping state of the palato-pharyngeal arch and the disappearance of the right arch, together with the difficulty in swallowing, all pointed in this direction, unless indeed the asymmetry were due to hypersensitiveness of the right side. The conclusion arrived at at an early period of the case was atony of the palato-pharyngeal muscle. The other muscles involved were the levator palati, circumflexus palati, and the retractor or azygos uvulæ muscles, which are supplied from the spheno-palatine ganglion. The levator veli palatini along with the action of the tensor veli palatini or circumflexus raise and expand the soft palate, while the azgos elevates the uvula. When the forces are still more closely followed the levator veli palatini raises, while the circumflexus or tensor veli palatini extends outwards the opening into the fauces. The opposite mechanical effect is produced when the constrictor isthmi faucium or palato-glossus and palato-pharyngeus are brought into action.

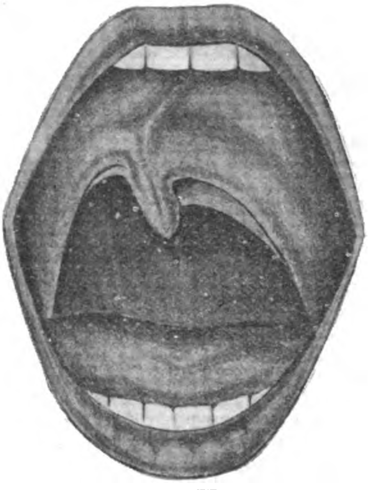

FIG. II.

In searching for a cause we cannot put aside the local inflammation in the throat which has been recently acknowledged by competent authors both in France and England to be a possible cause of neurosis of the motor nerves of the soft palate. Ephraim, of Breslau, records one of these rare cases where the uvula was affected; others are found in German literature where paralysis of the levator veli palati allowed the palate to droop in connection with a lesion of the vagus accessorius or facial nerve.

If no lateral deformity be present such as dragging to the healthy side, as in the present case, paralysis of the levator veli palatini alone might be inferred, but the case before us is unique in affecting one side only by a local inflammation, and as the asymmetry was only developed on phonation or intonation, it is just possible that the supreme effort of the right tensor veli palati or circumflex may be more energetic than the left, as seen in Figure II., where the raphé is drawn to the right.

The results showed that the greater elevation on the right side could not altogether be dependent upon the paralysis. The phenomena remained stationary during the following two weeks' treatment, while the electric current produced no tangible effect.

The following epitome may be repeated for a clear comprehension of the case. The complete elevation of the velum palati on the right side proved the integrity of the levator veli palati muscle as well as the circumflexus or tensor veli palati, while its hyperextension would be due to the loss of outward traction in the palato-pharyngeus. The passive uvula retains its normal position till disturbed by the displacement in the other parts by unequal forces, such as phonation, while the posterior pillar of the fauces hang down loose pointed to the paralysis of one isolated muscle, viz., the palato-pharyngeus.

After three weeks' treatment deglutition was performed quite freely. Inspection proved both sides of the posterior velum palati to be equally distended and the arcus palati normal in the power of distension.

ACTINOMYCOSIS OF THE LUNG
WITH
SECONDARY SKIN INFILTRATION
AND
MULTIPLE ABSCESSES
OF THE
CHEST WALLS.

By ROBERT KNOX, M.D. Edin., M.R.C.S., L.R.C.P. Lond.

A comparative study of the clinical course of actinomycosis of the lung and some forms of tuberculosis is interesting on account of the similarity which exists between the two diseases. So closely may actinomycosis of the lung resemble tuberculosis that it is only when a microscopic examination of the sputum is undertaken that a definite diagnosis can be made. Yet on closer analysis of the sets of symptoms differences can be detected which individually may be of little help, but when used collectively may point towards a positive diagnosis, or at least give rise to the necessary amount of doubt which leads one to carefully examine sputum and discharges for micro organisms. The striking differences between actinomycotic and tuberculous lung lesions are (1) nature of the expectoration, and (2) the character of the hæmoptysis. The physical signs in both diseases are so closely alike as to be practically identical, and as cases of actinomycosis of the lung may be and have been mistaken for tuberculosis it is of the utmost importance that this fungus should be looked for as well as tubercle bacilli. The following case illustrates this as well as other points of exceptional interest:—

Patient, a sparely built girl, æt. 18.

Family History.—Paternal: good. Grandmother alive, grandfather died at 70. Maternal: Grandfather died, æt. 44, of "bronchial trouble," and grandmother at 73.

Previous History.—Patient had enlarged cervical glands when seven or eight years old, these were operated upon and healed in due course. Whooping-cough and pneumonia in 1894.

Present illness commenced in April, 1901. About that time she had a number of alveolar abscesses which were troublesome and difficult to heal. She had a congested throat lasting for some time, was generally weak, and was working hard at school, in which she had distinguished herself. In June she went for a holiday to Perthshire, where she picked up, but in July contracted a severe cold and had pain under left shoulder. This apparently was pleuritic. The pain was severe and the temperature high; this was followed by an improvement in her condition for a short time, but there was a relapse with a rise of temperature. In August she was confined entirely to bed for three weeks, and the temperature rose daily until about August 26th it touched 103·5° F. in the evenings. There was some cough and diarrhœa, and the patient lost weight. She was closely watched by a medical man, who detected dulness of the apex of the left lung posteriorly. Under treatment she sufficiently improved by the end of August as to be able to begin the open-air treatment, and to take short walks, although the temperature still rose to 101° daily. This condition continued all September, and she returned to London early in October by short stages. She had gained 6 lbs. in weight during the three months in Scotland, the weight, including clothing, being 5 st. 6 lbs. On the evening of her return she had a slight hæmoptysis, not for the first time, but previous attacks were mere sanguineous streaks on the sputum. At this stage of the illness the writer was called in. There was dulness at the base of the left lung, extending upwards for about three inches; there was comparative dulness at the left apex anteriorly; breath sounds were defective at the base and bronchial at the apex. An abscess developed in the tender area of the back, extending from the apex of the lung to spine of scapula and vertebral column in the middle line. The abscess was opened and drained. The pus was thick, tenacious, yellowish green in colour and very offensive in odour. A slight improvement followed the opening of the abscess. Another and larger abscess then developed at the base of the left lung; there was considerable œdema of the tissues over it. Mr. Godlee saw the patient and suggested actinomycosis, with the result that his diagnosis was confirmed. The patient was immediately put on the potassium iodide treatment.

The skin surrounding the openings of the abscesses became involved, and after two months showed the following characteristic appearance:—

A number of small superficial abscesses which contained thick yellowish pus; a discrete papular infiltration of the superficial layers of the skin occurring in irregular patches and increasing by peripheral extension; the skin between the patches had an œdematous appearance and was of a bluish colour; the abscesses discharged and filled up with flabby granulations which soon protruded beyond the level of the surrounding skin; this tissue consisted of two distinct parts—pale, flabby, unhealthy tissue with centres of necrosis, which after a time were dislodged; the pus contained the characteristic fungus; soon an area of about a square foot became involved.

The patient was now (January, 1902) well under the influence of potassium iodide and showed signs of improvement, her spirits improved, she took food well and slept better than formerly. The temperature, however, continued to keep high and was not at this stage influenced by the treatment, although it was controlled with phenacetin in 5 gr. doses.

Other abscesses made their appearance in the back. These were opened and drained. Later, an abscess developed in the left supra-mammary region. It was opened and continued to discharge up to the termination of the case. A secondary abscess occurred in an axillary gland apparently by direct extension through the lymphatics. This abscess was particularly rich in the characteristic granular bodies. A large abscess appeared behind the sterno-mastoid muscle in the neck; it contained a large quantity of very offensive pus. This was the seventh abscess opened with the knife and all were without general anæsthesia, ethyl chloride being used for local freezing.

Throughout the course of the case alveolar abscesses appeared in the mouth, the pus from one of these was examined and contained the organism. The abscess in the neck appeared to be an extension from the alveolar abscesses. Gradually the discharges from the abscesses ceased, the skin affection improved greatly, but the patient steadily became weaker. Towards the end fresh pleuritic affections became evident, some consolidation of lung tissue appeared, and the patient gradually sank from exhaustion, five months after the detection of actinomycosis and twelve months after the first symptoms of illness.

Treatment.

It may be noted that the patient had always been dyspeptic and a poor eater, and in the early stages of the illness medicinal treatment was directed to relieve the gastric symptoms and generally to brace her up. As soon as actinomycosis was diagnosed, potassium iodide was administered in 5 gr. doses thrice daily, rapidly increased, so that within four weeks she was taking 80 gr. daily. At this it stood for two weeks, then 30 gr. were given thrice daily, and occasionally a fourth dose was given. In January-February the dose was still further increased to 55 gr. thrice daily, 60 gr. being given for a few days only. It was found that during the five months the patient took 16,320 gr. of the iodide, or an average of 103 gr. daily. In the first instance, 30 minims of tincture of gentian were given with each dose, but this was omitted at the patient's request, and apparently with benefit. It was also observed that if a dose of the iodide were given first thing in the morning, the patient felt brighter and better all day. Minute doses of perchloride of mercury were combined with the iodide on several occasions, but in about four days they induced diarrhœa, and had to be stopped. It may be noted that the maximum dose of iodide given was equal to 1 gr. per pound of body weight.

Symptoms of iodism were slight and easily controlled by increasing the dose of iodide. When the 30 gr. doses were reached there were no iodism symptoms, and it seems that there is little reason for hesitation in pushing the dose to the extreme limit by 5 gr. increase of dose every second day from the commencement. The influence of the drug was evidenced in several ways. The abscesses which developed late in the case healed more quickly than the earlier ones. Though the lung condition did not appreciably improve under the influence of the iodide, yet it apparently checked fresh extension of the morbid process.

The specific influence of the iodide upon the fungus was negative; throughout the course of the case frequent examinations of the sputum and pus were made, and no appreciable diminution in this respect was observed. The pus from the last abscess contained the fungus in as large numbers as in the earlier ones.

One marked effect was produced in the change which took place in the character of the pus. That from the later abscesses, with one exception, was distinctly less offensive than in the earlier ones, and there was no evidence of the presence of the pyogenic organisms which were so abundant in the earlier abscesses before the patient was fully under the influence of the iodide. During the administration of the iodide the patient steadily lost weight in spite of the large quantities of nourishment she took. The loss was due no doubt to the exhaustion caused by the lung condition.

The iodide undoubtedly aided in the marked improvement which took place in the skin affection. The treatment of this gave the most satisfactory results, and well illustrates the possibilities of cure in a simple case of actinomycosis of the skin. At one time the outlook was hopeless. The skin was rapidly becoming affected by peripheral infiltration. The affected area was studded with abscesses and ulcers in all the stages of discharge, granulation and partial healing. Double cyanide gauze was the sole application at first. This was followed by iodoform gauze, which did so much better that iodoform in large quantities (an ounce as emulsion daily) was used with marked benefit. This was changed to potassium iodide ointment with still greater benefit. Mercuric iodide (1 in 5,000) was added, but this ointment liberated free iodine on contact with the pus and had to be discontinued, the irritation and pain being intense. Peroxide of hydrogen was next used in diluted forms (1 part of 10 vol. solution and 15 parts water to begin with) by spray and dressings of lint soaked in the diluted preparation. Under its influence marked improvement was noticed, the discharge from the surface became less, the granulations were reduced and became healthy healing surfaces, and epithelium gradually covered the exposed parts. Towards the end the skin had practically healed. The writer would call special attention to this result, for peroxide of hydrogen not only acts as an oxygen carrier, thus giving the advantage of the oxygen treatment, but, as Mr. R. F. D'Arcy (*Philosoph. Mag.*, January, 1902) has shown, the particles of peroxide in decomposing are electrically charged, and it is not unreasonable to suppose that an unhealthy surface is benefited by this electric fluid. It is important not to use the preparation too strong. Most benefit was derived from one drachm of Tyrer's ten-volume peroxide in two ounces of water; one part of the peroxide and four parts of water acted as a caustic and delayed healing. The skin was washed daily with ethereal soap solution and occasionally with ichthyol and tar soap.

The case in the earlier stages was identical with tuberculosis of the lung—loss of weight, cough, expectoration, sweating, hæmoptysis, physical signs of pleural effusion, consolidation of lung and hectic temperature. The points of difference were (1) the nature of the expectoration, which was thrown off in smaller masses which were rounded and tenacious; it had not the nummular character so evident in a tuberculous case; it was not purulent. 2) The cough was very troublesome. (3) Numerous attacks of hæmoptysis occurred. They were never serious, and usually came on after a severe attack of coughing or when the patient lay on her right side. At no time did hæmoptysis threaten to render the outlook serious.

The abscesses appearing on the posterior aspect of the chest walls gave rise to doubts as to the nature of the case. They apparently originated in the pleura and pointing outwards appeared in the back. The first abscess led to a fistulous opening into the lung substance, and for a time air was forced out when the patient coughed. It communicated with a bronchus. This healed up on two occasions, but reopened, and was one of the most distressing symptoms during the last week of life.

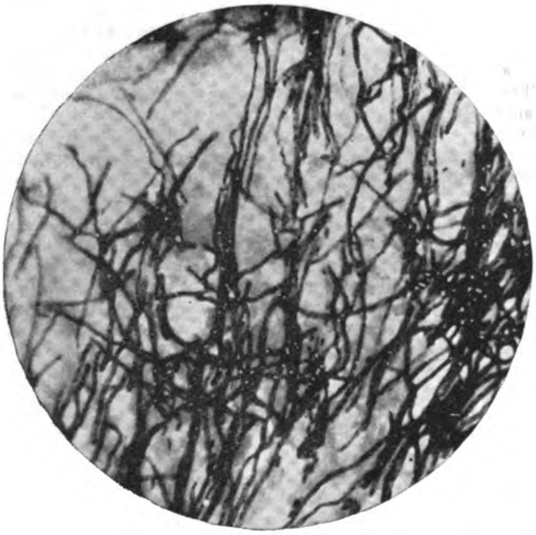
The lung substance appeared to be riddled with the growth, as proved by the occurrence of the abscess first on the posterior aspect and later on the anterior in the supra-mammary region. The latter abscess corresponded with the dulness over the left apex anteriorly. The pus from this abscess contained the fungus and also showed microscopic evidence of pleural origin. The right lung was comparatively free from active change, though there was evidence of pleural inflammation over the base posteriorly. The pericardium and heart remained unaffected. The abdominal viscera did not show any physical signs which would point to an implication of those organs. The urine did not contain albumin. The writer may here express his indebtedness to Dr. W. Harrison Martindale for frequent confirmation of the microscopic observations.

The point one would like to have cleared up in the therapeutics of actinomycosis is the nature of the action of potassium iodide on the morbid process. That it does not destroy the fungus is proved by the persistence of the organism in all the discharges and sputum examined at intervals during the time the iodide was administered. From the quantity of iodide given one would have thought that if it had any specific action it would have been manifest after the tissues had become saturated with it. The explanation may be that iodide acts by causing the absorption of the products of the accompanying inflammatory changes which the actinomycosis sets up in the tissues, and so leads to an arrest of the progress of the morbid changes This action was evident in that portion of the disease which was open to observation on the back. Undoubtedly the healing which took place there was due in part to the action of the iodide, and if it took place there presumably the same process takes place in the deeper structures.

Microscopic Examinations

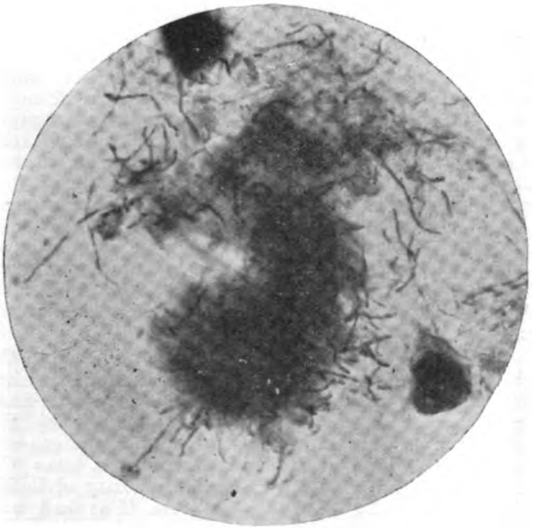
of the sputum and pus in the case above described have from time to time been conducted by Mr. W. Harrison Martindale, Ph.D. Marburg. It may be interesting to append a short synopsis of his reports:—

On November 16th, 1901, a specimen of pus, which had been removed from a large abscess on the back was submitted for examination, and was found to contain a fungus having the strongest resemblance to streptothrix actinomycosis. The typical yellow granular particles were traced in the pus, teased out, and stained by the Gram-Eosin method. On this, the initial examination, B. tuberculosis was also searched for with negative result.



Actinomycosis preparation from pus x 1,000.

On November 25th, 1901, a specimen of the patient's sputum was submitted. Here also the small lemon-yellow nodules were detected and stained by the Gram-Eosin method, and the mycelium of a fungus with the characteristic appearance of streptoactinomycosis was observed.

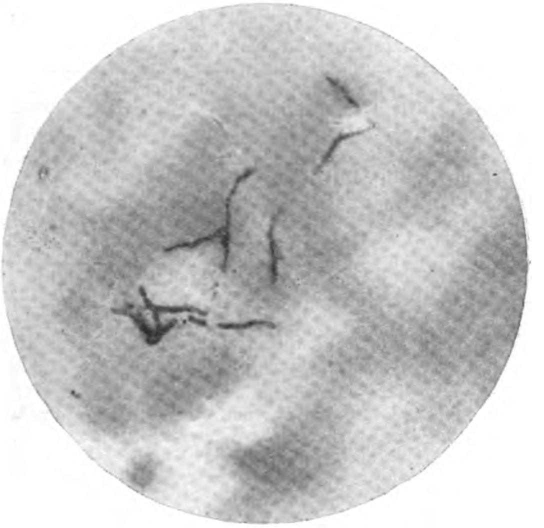


Actinomycosis cover-glass preparation from sputum x 1,000.

On February 20th, 1902, a further species of pus of pleural origin, which had been removed on lancing an abscess over the left breast, was again found to contain the parasite.

On March 10th, 1902, a further specimen of pus was sent for examination. This had been removed from an abscess which rapidly formed in the left axilla by direct extension from the supra-mammary abscess. Six films were prepared from this by the customary method, and found to contain the fungus. Coccus-forms staining by Gram's method were not observed.

On March 19th, 1902, some of the pus from an alveolar abscess of the patient was forwarded for examination. Eight films were prepared and subjected to careful search. In two only of these was there any evidence of the parasite, and the mycelium in these instances was in no way so typical or so markedly developed as that which had been previously detected from time to time in the pus.



Actinomycosis preparation from alveolar abscess x 1,000.

On March 20th, 1902, nine films were prepared from the typical nodules in a further specimen of pus. Some remarkably well-stained slides were obtained. No coccus-forms staining by Gram's method were observed.

To refresh the memory of those who have not recently had occasion to conduct a microscopic examination for the fungus in question, the most trustworthy method for identifying the fungus may be briefly detailed:—

1. The specimen should be poured into a flat glass dish with a sheet of black paper beneath. The characteristic yellowish particles should then be searched for, removed with the aid of a pair of fine-pointed forceps, and carefully teased out on a micro-slide or cover-glass.
2. The film is carefully dried over the flame, and "fixed" by passing through the gas jet three times, *secundum artem*.
3. The preparation is then stained with anilin-gentian violet solution for five minutes or so.
4. The surplus of stain is decanted, and the preparation is covered with Gram's iodine solution.
5. Washing with alcohol is now conducted until the washings are no longer violet tinted.
6. The preparation is then rinsed with water, and counterstained with a little aqueous Eosin solution for a few seconds. It may then be dried and mounted with xylol balsam.

Thus stained, the violet-coloured mycelium of the fungus in the form of tangled webs or scattered filaments will manifest itself on a pink ground (leucocytes, epithelia, &c.) on examination with a sixth of an inch objective, or it may, indeed, be demonstrated with a power as low as two-thirds of an inch.

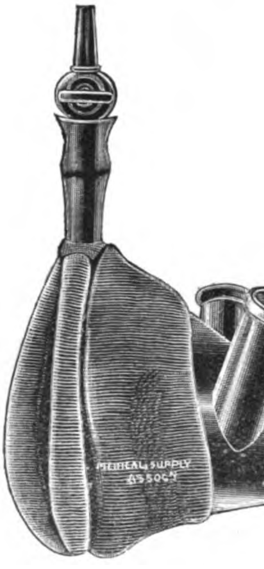
It need scarcely be said that in virulent cases the fungus may be found by simply working on a small quantity of the pus, &c., without searching for the characteristic nodules. Furthermore, the "rays" may be observed without staining, but the stained specimens are confirmatory and valuable for reference.

THE PROLONGATION OF NITROUS OXIDE ANÆSTHESIA FOR DENTAL OPERATIONS BY PATERSON'S METHOD. (a)

By T. PERCY C. KIRKPATRICK, M.D.,
Anæsthetist to the Dental Hospital, Ireland.

The results which have been obtained by the use of nitrous oxide and oxygen, and even nitrous oxide and air, in producing and maintaining anæsthesia for general surgical operations, have from time to time strongly suggested to anæsthetists its possibilities for the more prolonged operations in dental surgery. Since the introduction of this anæsthetic by Horace Wells in 1844, it has always been looked on with particular favour by dental surgeons, and this is not to be wondered at when we consider the conditions under which most of their operations are performed. The one great drawback to its use was that the duration of available anæsthesia could only be reckoned by seconds even in the most favourable cases. To obviate this difficulty, and to devise some means by which the gas might be administered during the performance of a dental operation, has been the object of much investigation among anæsthetists of recent years, and in this connection the names of Coleman, Coxton, McCardie, Hilliard and Paterson stand prominently forward as pioneers. The work of these men has abundantly proved the possibility of so prolonging nitrous oxide anæsthesia, but whether it was from the complication of the apparatus or difficulties in its use the methods recommended never appeared to find much favour. About a year ago I started working on this subject, and used for my experiments a mouth tube slightly modified from the pattern suggested by Mr. McCardie, of Birmingham. With this apparatus I got fairly good but not uniform results. I was able to get on several occasions quiet anæsthesia for as long as four and a-half minutes, but on other occasions I was unable to materially prolong the ordinary gas anæsthesia, and attempts to do so were attended with rather disastrous results. My failures were mostly with men, while the good cases were mostly with women. Even in the cases which might be fairly called successful the method was open to very grave objections. The apparatus was very difficult to manipulate single handed, while a great deal of gas was used, and the apparatus was cumbersome and complicated. I also found that the stream of cold gas entering the mouth condensed the moisture in the expired air, which, issuing like a cloud of steam from the mouth, greatly impeded the view of the surgeon. In the face of these grave drawbacks I determined to try the nasal inhaler devised by Mr. H. J. Paterson, Anæsthetist to the Dental Hospital of London. I began using this apparatus in June of last year, and since that time have only used ether in five cases in my hospital practice out of a total number of 495 cases. I do not wish to be understood as claiming that these 490 cases were all uniformly successful, some of them were and some of them were not; but as I got more experience the percentage of good cases became greater, and now an unsatisfactory anæsthesia is the exception, and I am glad to say a rare exception too. This improvement in my results I attribute to two causes—first, increased experience as the result of practice; and secondly, an improvement in the form of the apparatus which that experience has suggested. Paterson's apparatus, which is made by Messrs. Barth and Co., consists of a small metal cover made to fit the nose accurately with the aid of a rubber pad. Two small metal tubes are let into the nose-piece, and to these are attached two rubber tubes which lead to an ordinary gas bag, a two-way stop-cock intervening. In using the apparatus the nose-piece is placed *in situ*, the bag being filled with gas and the stop-cock turned on. The patient is now breathing gas through the nose only, and expiring through the mouth. The use of the mouth cover is, Paterson says, not absolutely essential, but it diminishes the period necessary for the production of anæsthesia, and so economises gas. At the time when Paterson first described his apparatus the longest period during which he had maintained anæsthesia by its means was nine minutes and fifty-five seconds. This was at a public demonstration at Cambridge on a man, æt. 35. The patient was kept absolutely quiet and recovered after a very few minutes. During anæsthesia two teeth were prepared for crowning and eighteen teeth extracted. Probyn-Williams, writing in September, 1901, states that the longest time for which it has been employed is fifteen minutes. When I first began to use this apparatus I found great difficulty in getting my patients to inspire by the nose and expire by the mouth. I was never able to anæsthetise them without the use of the mouth cover, and even with it often had great difficulty. To obviate this I had a nose-piece made with an ordinary expiratory valve, so that the patients breathed entirely through the nose and I was able to induce anæsthesia with the mouth closed. This method I found a very decided improvement and much more agreeable to the patients. The success of this method of administration entirely depended on the establishment of nose breathing during the induction of anæsthesia, and trusting that the habit so formed would persist during its maintenance. This answered very well in a certain number of cases, notably in intelligent patients and in that class of person such as women and young men, who are particulary favourable subjects for gas anæsthesia, but the continuance of the anæsthesia was quite beyond my control as long as the air way from the mouth was open. It will be obvious to everyone that with each inspiration the pressure in the naso-pharynx and larynx being lessened if the passage from the mouth were open, air must pass in, and so the gas being diluted the anæsthesia would pass off. In order to get over this difficulty, I was in the habit of introducing a sponge into the back of the mouth, so as to occlude, or at all events limit, the air way from it. This, though it acted fairly well, was open to many objections, and I found that though it materially increased the number of good cases, still a certain proportion were unsatisfactory. The sponge was often in the way of the operator, and, if it were pushed far enough back to make it thoroughly effective, it often completely occluded the air way and the patient, getting neither air nor gas, rapidly became asphyxiated. I must admit that at this stage of my experiments I became very disheartened with the method, for though I felt that often as I might deserve success yet I never could command it, and those cases in which I wished for it most were those in which I got it least. It was obvious that what was needed was some method by which we could compel the patient to breathe the gas fairly free from the admixture of air, and only admit at will so much air as was necessary to prevent asphyxia during the maintenance of a prolonged anæsthesia. This had, I felt, to be effected without the introduction of any apparatus into the mouth, for any such procedure would so complicate the method that it would seriously cripple its general utility. In the solution of this difficulty I had to return to Paterson's original model of the nose-piece, so that by increasing the pressure in the gas-bag I was able to raise the gas pressure in the naso-pharynx to such an extent that the soft palate was pushed forward against the tongue, so closing the mouth way from behind, and enabling the gas to pass freely and without admixture of air into the lungs with each inspiration. This, of course, was Paterson's original idea, and to efficiently carry it out a closed nose-piece during the maintenance of anæsthesia was a necessity. By the simple mechanism of fitting a movable cap over my expiratory valve I was able to shut this valve out of action, and had at will either a valved nose-piece for the induction of anæsthesia or a closed one for its maintenance. With the use of this apparatus I have had most excellent results, results, too, which are, I believe, as uniformly good as can be obtained in any form of gas anæsthesia. This gain in efficiency has been obtained without any sacrifice in the simplicity of the original apparatus, and without introducing any complication in the method of its use.

(a) Paper read at the meeting of the "Odontoblasts Club," April 28th, 1902.



Nose-piece modified from that of Paterson, with expiratory valve, the cover of which can be rotated so as to close the slot and put the valve out of action.

There are a few practical points which experience has taught me are essential to success in carrying out the administration, and as they may be of use to those who intend to use it I shall mention them briefly.

It is of the greatest importance to see that the nose-piece fits accurately, and that it is properly inflated, for if it is not it is impossible to exclude the air from entering by the nose, and imperfect anæsthesia will be the result.

Patients, as a rule, object very much to having the mouth propped widely open during the induction of anæsthesia, indeed, I have been told over and over again by patients that it was the one thing in the anæsthetic that they objected to. In using the valved nose-piece, it is distinctly an advantage to have the mouth closed during the induction, so as to insure a more regular and complete nose breathing. It is very important to make sure before starting that there is sufficient space between the teeth for the introduction of a Mason's gag, for if there is not the teeth are often so completely closed that it may be impossible to open the mouth without a degree of violence, which may be injurious to the teeth. For this purpose, I use a small mouth prop which is just sufficient to separate the teeth, but not large enough to keep the patient from closing the lips. It is not necessary to put the patient nearly so deeply "off" with this method as with the ordinary one, for as soon as anæsthesia has been induced the operation may be started, and during its continuance the anæsthesia may be continued at the same level or deepened as circumstances require. I find the time required to induce anæsthesia is considerably longer than that stated by Hewitt in his account of the method. From careful inquiry among intelligent patients I find that they generally lose consciousness after from seven to nine respirations, and it needs several more before the reflexes are abolished sufficiently to permit the operation to be proceeded with. I find the average time taken to induce anæsthesia is between three-quarters and one minute. The most trustworthy signs of anæsthesia are a slight loss of the red colour of the lips, not amounting to actual cyanosis, and as this becomes evident there is an alteration in the rhythm of respiration, it becoming a little deeper and more frequent. The conjunctival reflex is dulled or lost, while the corneal reflex is practically unchanged and the eyeballs tend to become fixed, or there is a slight lateral nystagmus.

When anæsthesia is established I shut off the expiratory valve anddistend the gas bag so as to have the gas in the naso-pharynx under a certain pressure before the mouth is opened. During the continuance of the administration the bag must be kept distended, and if there are any signs of the anæsthesia passing off all that is necessary is to slightly increase this pressure at the beginning of inspiration. Movements generally indicate want of oxygen which can best be given by reducing the gas pressure and so letting air enter by the mouth; phonation indicates too light an anæsthesia and calls for an increased gas pressure. If there is deep cyanosis the administration should be stopped for one or two respirations; if apnœa has been induced the administration should be stopped entirely till either the colour or the respirations again return, but provided the pupil is not dilated there is no need to interrupt the operation. If the breathing stops and there is cyanosis with dilated pupils the operation should be interrupted till the respiration is again re-established. This latter condition I have never met with yet. If in spite of the precautions which I have mentioned the patient shows signs of coming to it is best to stop the operation, open the expiratory valve, close the mouth and so reanæsthetise the patient. I find that if this is done they seldom remember the interval, no matter how conscious they may appear to have been.

As regards results, these may be looked at from three different points of view—that of the patient, that of the operator and that of the anæsthetist.

From the patient's point of view there is no comparison with ether anæsthesia. The taste of the ether, the nausea and prostration which follow in the vast majority of cases where it is administered even for very short periods is without counterpart in gas anæsthesia, even after its prolonged use. Of course it is needless to remark that a patient who has been anæsthetised for four or five minutes while eighteen or twenty teeth have been extracted will not feel so well as after an administration, the available anæsthesia of which is measured by seconds. There are two objections to the method from the patient's point of view: one, which is common to any gas anæsthesia, is that the patient wakes up so quickly and completely that a good deal of the immediate after soreness is felt. The other objection is that after a prolonged administration there is often a good deal of headache, but this does not as a rule last long and certainly is not worse than after ether.

In a certain number of cases there is undoubtedly a good deal of discomfort after a prolonged operation under nitrous oxide anæsthesia, but how far this is to be ascribed to the anæsthetic and how far to the operation it is difficult to determine. Patients are apt to think if the operation has been performed under gas anæsthesia that no matter how prolonged it may have been they should be no more incapacitated than when only one or two teeth have been extracted. In consequence they endeavour to return at once to their ordinary occupations, and are surprised to find that they suffer from symptoms of shock for some days after. It should be remembered that after a prolonged dental operation, where many teeth have been extracted or where there has been much laceration of the gums, there is likely to be much more shock than in many of the minor operations of general surgery. To this shock must be added the almost inevitable result of a certain amount of septic absorption from the open wounds in the mouth. Such patients should be carefully prepared for operation by having their bowels well moved by some purgative medicine, and, if to this is added further purgation after the operation with enforced rest and antiseptic treatment of the mouth, little will be heard of unpleasant after effects of the anæsthetic. In cases where the anæsthesia is attended by much cyanosis there will undoubtedly be unpleasant after effects, such as headache and depression, but such cyanosis is not in any way a necessary result of the method and should always as far as possible be avoided. While laying stress on these after effects, I would emphatically point out that they are the exception and not the rule, just as we find in exceptional cases after ether anæsthesia there are no unpleasant after effects, so after prolonged gas anæsthesia in exceptional cases we meet with unpleasant results.

From the operator's point of view there is, I think, no objection to be urged. He starts his work, be it much or little, with the knowledge that he has ample time to finish it without hurry, and with the knowledge also that if any accident occurs, such as the fracture of a tooth, he has time to remedy it. The objection urged by Hewitt, that "though absolute immunity from pain may be secured yet the type of anæsthesia can hardly be regarded as satisfactory in the modern sense," can hardly be maintained since the type of anæsthesia is in the majority of cases quite as good as that of nitrous oxide and oxygen, or ether. The advantage to the dentist of the speedy after recovery of his patient without sickness is one which is greatly appreciated.

The chief advantage that the anæsthetist gains is the knowledge that he is doing the best for his patient and the operator, since as a rule it will be undoubtedly easier for him to prolong anæsthesia by the administration of ether than by gas, the latter, too, being more expensive, but to these objections little weight can be attached. As compared with nitrous oxide and oxygen he is at a distinct advantage, since the apparatus is much more simple and portable and not nearly so expensive, and in similar operations very much less gas will be used. Although it is an advantage, it is not by any means necessary, to have an assistant present during the operation; there is no more necessity for such assistance than when any other anæsthesia is employed. The anæsthetist can manipulate the apparatus and steady the head with one hand, gas being admitted from the bottles by the foot key in the ordinary way, while the other hand is at the disposal of the gag. I think we may claim without reservation that every dental operation which can be done with gas and oxygen can be done as well, if not better, by this method, while many others which cannot be done with gas and oxygen at all can with ease and safety be done by this new method.

As to the results which I have myself already obtained by the method during the present year in my hospital practice, I would add briefly the following particulars:—

The longest period during which I have administered gas by this method is seventeen minutes, in a man, æt. 20. There was fifteen minutes of perfectly quiet anæsthesia, during which time thirty teeth were extracted, some of them being very difficult. The patient made an excellent recovery, without any bad symptoms. I have had six cases in which there was over ten minutes of available anæsthesia, and sixty-one cases in which it was of three minutes or upwards.

The following are the results of a recent morning's work at the hospital:—

Patient's Name.	Age.	Operation.	Remarks.
John W. ...	20	13 teeth	1½-3m very quiet.
Frank L. ...	13	4 teeth	¾-1m excellent.
Robert B. ...	16	5 teeth	1-1¼m some cyanosis.
George P. ...	21	6 teeth	1-3½m slight cyanosis.
William G. ..	16	8 teeth	¾-1½m excellent, quiet.
Private H. ...	20	6 teeth	¾-2½m very good case.
Jervis C.......	12	5 teeth	¾-2¼m a little movement.
Joseph F. ...	15	6 teeth	1-3m very good.
Michael C. ...	16	6 teeth	1-4m excellent case.
Claud McD...	20	23 teeth	1-7m excellent.
Violet F. ...	22	13 teeth	1-2m a little hysterical after.
Michael C. ...	14	2 teeth	1¼m very good.
James McG.	23	6 teeth	1-10m excellent all through.

We were one hour and thirty-five minutes getting through these cases without any undue hurry, and I used just 200 gals. of gas, during administration extending over 51¼ minutes, an average of between 3 and 4 gals. per minute.

CAPTAIN W. Cox, of the Indian Medical Service, has been mentioned in despatches for gallant conduct in the Mahsud-Waziri blockade.

A CONTRIBUTION TO THE STUDY OF TROPICAL ABSCESS OF THE LIVER. (a)

BY RICKMAN J. GODLEE, M.S.LOND., F.R.C.S.ENG.,
Holme Professor of Clinical Surgery, University College, London.

IN the course of an experience of tropical abscess of the liver somewhat large for an English surgeon, though ridiculously small as compared with that of those practising in the tropics, I have been led to think about the disease and its complications, and I trust that the following contribution to its study may be, if disjointed, not therefore without interest. Possibly it may elicit some useful comment and criticism, and it is on this account that the statements contained in it are somewhat dogmatic. I will deal first with some of the complications.

Perihepatitis, usually perihepatic peritonitis, is an almost invariable accompaniment of tropical abscess, and must always exist to a greater or less extent when the abscess reaches the surface of the liver, but it is astonishing how little there is in some cases even when the matter has approached within perhaps half an inch of the surface. If there be no adhesions the introduction of an exploring trocar or an aspirator needle into the liver will be probably immediately followed by the escape of pus into the peritoneal cavity. Supposing the needle has been introduced for the sake of discovering the existence of an abscess, and the operation for its evacuation be immediately proceeded with, there may yet have been time for a quite considerable quantity of pus to have escaped in the few minutes which have elapsed before the peritoneum is reached. It is even possible to mistake this free pus for the abscess itself. The further exploration of the liver under these circumstances is essential. It is scarcely possible under these circumstances to sew the liver up to the abdominal wall, as each stitch will most likely enter the abscess cavity and the stitch holes will leak. It is safer, therefore, to pack round the part where the incision is to be made before the abscess is actually opened, and after the opening has been made to manipulate the parts as gently as possible. Perihepatic peritonitis is the cause of the acute pain that is often met with as distinguished from the typical liver pains. This pain is, of course, superficial, and is accompanied by acute tenderness, easily elicited by even light percussion. Peritonitis occurs often in definite attacks, accompanied by fever and vomiting, and often yields a useful physical sign—*i.e.*, *friction*, which may be felt with the hand and heard with the stethoscope over the liver. It exercises a protective effect by shutting off the part into which an abscess is pointing, so that when rupture occurs a sub-diaphragmatic abscess results, and not a general peritonitis.

As might be expected, peritonitis most commonly affects the convex surface of the liver, which thus often leads to the adhesion in whole or in part of this surface of the liver to the diaphragm. When this has occurred an enormous amount of pus may accumulate in the liver without giving rise to any enlargement downwards, and the enlargement upwards may only be indicated by partial dulness in the lower part of the chest; the dulness is least marked when the lung is adherent to the pleura because the lung cannot be then displaced upwards by the approximation of the diaphragm to the chest wall. Perihepatic peritonitis may also occur on the under surface of the liver and may then give rise to very serious results. The stomach, duodenum, and colon may become firmly adherent to the liver and after the abscess has been evacuated the consequent contraction may lead to considerable displacement of these viscera, giving rise to such troubles as dilated stomach from kinking of the duodenum. But it is a much more serious thing if the transverse fissure and the small omentum have been the seat of the peritonitis, for any one or all of the hepatic ducts may be partially or completely obstructed.

The escape of the whole of the bile through the wound is fortunately not of common occurrence. I have never before met with it in cases of tropical abscess, though I have seen it in hydatid of the liver. It does not necessarily lead to loss of appetite or difficulties in digestion, but it sooner or later causes emaciation which may become extreme. I have seen bedsores form over the projecting angles of the ribs and angles of the scapulæ. I am permitted by the kindness of my friends, Dr. Manson and Sir W. H. Bennett, to mention the only other two instances which I have heard of in connection with tropical abscess, and I would suggest that in fatal cases the same condition as that which occurred in the one that I have just described will be met with. In Dr. Manson's case the patient died after four months in a state of extreme emaciation, though the fistula was apparently beginning to close; and in Sir William Bennett's case the sinus gradually closed after seven months, and the patient made a complete recovery. In connection with this subject, reference may be made to cases, with which all will be familiar, where there is complete obstruction to the common bile-duct either from calculus, tumour, or inflammatory adhesions. These patients do not, so far as I have seen, emaciate; on the contrary, their nutrition may remain fair for years, and it is quite remarkable how long the fatal event may be delayed.

(a) Abstract of a Paper delivered before the Royal Medical and Chirurgical Society on May 13th, 1902.

It has been shown by the beautiful observations of Klein that the direction of the flow in the lymphatics of the diaphragm is upwards. As might, therefore, have been expected, pleurisy is a very common accompaniment of tropical abscess. It is a useful diagnostic sign. It is also a note of warning. Rupture into the pleura is in my experience one of the most dangerous outcomes of this disease. I could, if it were advisable, give more than one example of this catastrophe being followed by the most extraordinarily rapid pleural effusion. In one, indeed, though I saw the patient within twenty-four hours of the rupture of an abscess which had for so many months remained dormant that its very existence had been doubted, the patient appeared to be moribund, and the pleura contained an enormous amount of fluid. But even when the pleura is opened at once, if the lung has not previously contracted adhesion to the chest wall, it is not unlikely that it may collapse against the spine and never expand again, and the most extensive Estlander's operations may fail to effect a cure. The patient, therefore, who has extensive pleural adhesions is saved from very grave dangers.

It would often save trouble and anxiety if the presence or absence of such adhesions could be determined. This is, however, notoriously difficult and often impossible, which is my excuse for mentioning two aids to diagnosis which have not, I think, received sufficient attention. 1. The upper level of the dulness caused by a liver which is enlarged upwards is, speaking generally, considerably lowered when the patient is placed on his left side. If, however, the lower part of the pleural sac is obliterated by adhesions this does not occur, because the lung cannot be sucked down into the pleural sinus by the falling away of the liver—that falling away which so frequently causes pain when the patient attempts to lie on the left side. 2. In very thin people, even when the parts are normal, I have pointed out (a) that it is often possible on careful inspection to see the lower margin of the lung on the right side move upward and downward during respiration. It may sometimes be observed on the left side, especially if the spleen be enlarged, or if there be a great enlargement of the left lobe of the liver, or, indeed, any tumour in this situation; and on the right side it is more obvious when the liver is enlarged than when it is of normal size. This sign requires somewhat careful inspection for its discovery and it is only of use in emaciated or very thin subjects. If it be present it is a certain proof that there are no adhesions in this situation and that there is little or no pleural effusion.

In connection with the question of adhesions I desire to make a practical suggestion. If the incision for opening the abscess has necessarily to pass through the pleura below the lower border of the lung it is often difficult or impossible to tell whether the cavity is obliterated by lymph or not. I have more than once cut down through both layers of the pleura and as no air has entered I have gone on to incise the diaphragm and liver. On withdrawing the finger, however, the ominous sound made by air rushing into the chest has shown that the two layers of the pleura were at first only held together by the attraction of cohesion or by very feeble adhesions, and a laborious process of stitching up the hole had to be undertaken. The right way to proceed, if there be any doubt, is to cut through the diaphragm across its fibres at the part nearest its costal attachment and to sew up a flap of the muscle to the intercostal muscles at the opposite end of the wound. The incision into the abscess can then be undertaken without fear of producing pneumothorax. By adopting this precaution I do not expect to meet with the above-mentioned accident again.

Pleurisy may lead to serous effusion, or to empyema, without any rupture of the liver abscess through the diaphragm, and such an effusion may keep up the temperature after the successful evacuation of the hepatic abscess. I once opened a large tropical abscess on an Indian army surgeon who was in an extremely exhausted condition. There remained some dulness in the back and the temperature did not fall to normal. The removal by aspiration, several days later, of a few ounces of clear fluid was immediately followed by disappearance of the pyrexia and from this time the patient made an uninterrupted recovery. On another occasion, when the physical signs and symptoms were almost the same, the fluid was pus, and an equally good result followed the insertion of a drainage-tube into the pleura. A less successful result followed in the case of a young officer whom I saw with Dr. Ringer and whose abscess I had opened in the lower axilla. Repeated attempts at aspiration of the chest were unsuccessful, because there was much recent lymph as well as fluid in the pleura. In the hope of securing better drainage I made a second incision into the abscess behind, and in doing so found that I had opened the pleura and a considerable quantity of clear fluid and large masses of lymph escaped. Thinking that some of the pus from the abscess had probably entered the pleura I therefore placed through this second opening one tube into the abscess and one into the pleura, but I am sure it would have been better to have sewn up the opening in the pleura and to have left this cavity for treatment later; for the recent pleural adhesions gave way owing to the violent coughing of the patient, the lung collapsed, and a general pneumothorax was produced. The case was a very septic one and a fatal result was probably inevitable, but I think that it was hastened by the pleural complication. I said that the existence of friction was an *ominous* sign, for although rupture into the lung, as everyone knows, often leads to a rapid cure of the disease, no one who has seen the disastrous results that may ensue would dream of waiting for it to occur. *When there is marked pleural friction, therefore, exploration of the liver should be made without delay.*

I am thus led to the next part of my subject.

Changes that take place in the lungs.—It is obvious that in every case in which an abscess bursts into the lung a certain amount of lung tissue must be destroyed and an abscess of greater or smaller extent must be formed. In those which recover in a short time this is a negligible quantity. But it is often far otherwise. The next most favourable cases are those in which a small abscess forms in the lower part of the lung either in front or behind. Most commonly the signs of cavity will be met with below and to the inner side of the right nipple; but the cavity not infrequently occurs behind, and in rarer cases a liver abscess bursts into the left lung and forms a cavity there. If such abscesses are opened as soon as they are discovered it is probable that they will heal readily. But if operation is delayed a series of phenomena may occur that are not unlikely to give rise to a very chronic condition which may end fatally. These abscesses do not behave like those resulting from pneumonia, injury, or tubercle, but have a peculiar tendency to burrow by means of long and intricate tubular processes which are very difficult to follow up and drain, and may lead to the gradual destruction of large areas of lung tissue. I have seen one lobe almost completely disorganised in the course of an illness extending over many months. The suppurating tracks are sometimes in the lung itself, sometimes partly in the lung and partly in the pleura. The pus discharged from them has the characters which we are accustomed to associate with liver pus—that is, it is inodorous, thick, slimy, and chocolate-coloured, and may contain the amœba coli, so that I am inclined to believe that the peculiarity of the process depends upon the presence of this parasite. In these cases hæmorrhage is a common symptom; it is often frequent and severe and occasionally is fatal. The continued discharge of what has been recognised as liver pus has led to the assumption that the abscess of the liver is still unhealed; but this is certainly not always the case, for I have met with an instance in which the patient, a young man from an unhealthy Indian tea-garden, died from hæmorrhage, and at the post-mortem examination so little trace of the liver abscess remained that the medical man who made the necropsy stated that there never had been an abscess of the liver at all. This, however, I knew to be incorrect, for I had had my finger in the patient's liver, and the observation did not surprise me for I had been struck with the complete way in which all traces of a liver abscess even of large size may disappear. This is surely a not unimportant fact in making a prognosis, and it accounts for the completeness of the cure if recovery takes place. It is also interesting to note that if an abscess forms in the left lung, as a result of the inspiration of matter from the opposite side, the pus formed in it may be slimy and chocolate-coloured like that which came from the original abscess. I do not mean to say that chocolate-coloured pus may not come from a primary abscess of the lung; it may do so, but physicians will agree that this is a most exceptional occurrence. *It may be safely stated that the persistent discharge of chocolate-coloured pus does not prove that the liver abscess is not healed.*

(a) *Brit. Med. Jour.*, Jan., 1900.

Another danger to which a patient with an imperfectly drained abscess of the lung is exposed is abscess of the brain. I have met with two such cases following tropical abscess. In one I opened the abscess myself, and in the other I directed the operation; both ended fatally.

The practical deduction from what has been stated is that *pulmonary abscess consequent on hepatic abscess should be opened without delay*, and that a careful search should be made for outlying suppurating tracks; that these should be drained by the insertion of full-sized tubes, and, as far as possible, laid freely open even if this should necessitate extensive removal of ribs; and, finally, that the tubes should not be removed or shortened until the surgeon is satisfied that closure of the abscess is almost complete.

Dr. Manson, with whom I have been associated in several of the cases that have come under my care during recent years, has shown that in the majority the amœba coli is present in the pus. In some its presence is more easily demonstrated a few days after the abscess is opened than on the day of operation. In some it is found in abundance many weeks later, when the case is perhaps pursuing a normal course towards recovery. There is, therefore, strong suspicion that the amœba has something to do with the causation of tropical abscess. This persistence of the organism and the very slight effect which it may, under some circumstances, produce, possibly account for one of the most striking features of this disease—its occasional extreme chronicity. One cannot fail to be struck with the long periods of time during which an abscess may be latent, with the way in which symptoms that point strongly to the existence of an abscess may disappear, and with the comparatively slight disturbance of health that is not inconsistent with the presence of an abscess. I have known a young officer who was suspected of having an abscess go through a winter's hunting and return to show himself, as he thought, well, though the abscess was almost pointing at the epigastrium, and it is well known that an abscess may show itself years after a patient has returned from the tropics.

Some abscesses, on the other hand, after a long period of latency, suddenly become acutely septic. These cases most likely become infected from some part of the intestinal tract with the bacterium coli commune or some other septic organisms.

Some liver abscesses contracted in the tropics are, on the other hand, acute and septic from the first. These should, I think, be placed in a class by themselves and are not, properly speaking, examples of tropical abscess but are part of a general pyæmic process. They may arise in this country. They are often multiple and, as far as my experience goes, are quite hopeless cases to treat. But some genuine tropical abscesses are very acute. I saw lately a young man from Central Africa who had had many attacks of fever but no hepatic symptoms till he reached Europe on leave. In the course of a few weeks he developed a small abscess in the right lobe. It was easily reached and it healed in a shorter space of time than any other case I have had to treat, a very few weeks sufficing for the cure.

The majority of tropical abscesses that I have seen have been single and I believe that many of the cases which have been reported of a second abscess following the first are those in which the drainage-tube has been removed too soon or in which a diverticulum of the original abscess has never been properly drained and has been shut off from the main cavity. I think it is of great importance at the time of the operation to explore the cavity very carefully with the finger and to open up all branches of it, as far as possible, before the drainage tube is inserted. I am, of course, not likely to forget that the cases which we see in England have been sent home from distant parts of the world, and am prepared to hear that others of a totally different type may be met with by surgeons who are on the spot where the disease originates. I have, indeed, been frequently told that we in England do not see the really bad cases, which may be true, though it must be owned that some of them are bad enough in all conscience.

The last point I would deal with is the question of the *best place to make the incision*, and I will begin by stating that I consider that, if possible, the seat of election for the operation is in the lower axilla. If two lines be drawn vertically downwards, prolonging the anterior and posterior folds of the axilla as far as the margin of the ribs, they will at the lower part inclose the space where the widest interval intervenes between the lowest part of the pleura and the costal margin, an interval generally of two inches and often even greater. The incision may conveniently be made transversely—that is, parallel with the lower margin of the pleura—and the portion of one rib and cartilage that crosses the wound obliquely should be removed, great care being taken to separate the structures on the deep surface of it without injuring the pleura in case by chance it should extend lower than usual. Generally the structure thus exposed consists only of the origin of the diaphragm, but if the pleura should be low it is easily recognised and may without any difficulty be dissected up without injuring it and fastened out of the way to the upper part of the wound. If it should accidentally have been opened the suture of the opening is a simple matter and it is essential to make it perfectly air-tight before proceeding. The rest of the operation consists in incising the diaphragm, either in the direction of its fibres or across them (I prefer the former method), and then cutting through the diaphragmatic peritoneum. If there be no adhesions the liver may either be sutured to the diaphragm and the chest walls or the parts around the opening may be carefully plugged with some antiseptic material. If the latter course be adopted it must not be forgotten that if the abscess be large the liver will at once shift its position and that this shifting will take place in the upward direction.

It may be asked, "Why lay down this dogmatic rule when it is well known that the abscess may occur in any part of the liver?" But to this it may be answered that, in my experience at all events, by far the majority of abscesses occur in the right lobe, and that if they be of large size they can generally be opened in this situation even if they form a projection in the epigastrium or most nearly approach the surface behind. I have already referred to the difficulties and dangers of incising the liver behind, depending upon the fact that it is necessarily a transpleural operation. The epigastric incision does not drain well and I am therefore in the habit, even if the abscess appears to be pointing in this situation, of ascertaining, to begin with, whether or no the matter can be reached at a moderate distance from the side. It is a question whether, if this be found to be the case, and after making the lateral incision the epigastric tumour disappears, the surgeon should be content, or whether he should make an epigastric incision as well. A case recently under my care and referred to in an earlier part of this paper supplies an argument in favour of the latter course. I had been content with the single incision in the side, but it turned out that the epigastric swelling had been caused by a localised peritoneal collection of matter due to the bursting of the abscess in front. The communication was not, however, sufficiently free to allow of satisfactory drainage, and it was necessary to make the anterior opening in the course of a few days.

I do not deny that the epigastric incision is the only possible one in certain abscesses in the right lobe and in all of those that occur in the left lobe. I would strongly deprecate a lateral incision below the costal margin, because the opening is certain to become troublesomely oblique in the course of a few days as the liver shrinks up under the ribs. The opening into the liver itself may conveniently be made with a long pair of dressing forceps followed by the finger. In this way abscesses at a great distance from the surface may be safely reached and effectually drained. Hæmorrhage is often free, but it usually stops spontaneously if the finger be retained for a minute or two in the wound. Should it not do so careful plugging round the tube must be practised. Some cases bleed extensively after the operation and the bleeding occurs on subsequent occasions. I am not referring to the slight hæmorrhages which often occur for many days in cases which are pursuing a normal course, but to those in which the loss is considerable. I look upon this as a grave sign and I think it occurs most in the septic as opposed to what I have called the amœbic abscesses. A certain amount of blood often escapes into the peritoneum as the result of the preliminary puncture. It seldom is of any moment, but dangerous and even fatal cases of exploratory puncture have been recorded. It is not unlikely that these patients are either jaundiced or suffering from leucocythæmia.

I cannot conclude without referring to Dr. Manson's ingenious device of introducing a drainage-tube through a large trocar plunged boldly through all the superficial tissues into the abscess. It has yielded excellent results in the hands of many and I would not say a word against it. But for my own part I prefer to know in what condition I have left the pleura and peritoneum, and to have ascertained what the size and shape and possible ramifications of the abscess may be, to have opened these up if it appears to be necessary to do so, and to have placed the tube or tubes in what seems to be the best position for the future draining of the cavity.

Lunacy Department.

ASYLUM REPORTS.

Montrose Royal.—The following changes have occurred during the year, viz.:—190 admissions, 110 discharges, and 57 deaths. Hereditary predisposition and alcohol are recorded as causes of insanity in 26 and 16 per cent. of the admissions respectively. The recovery rate was 35·2 per cent. (below the average), and the death-rate 8·6 per cent. About 16 per cent. of the deaths were due to phthisis. The detached villa for sixty quiet male patients has been completed and is in occupation, and the Commissioner reports the internal arrangements to be in a high degree satisfactory. Besides completely relieving the overcrowding on the male side, it proves a welcome addition to the curative resources of the institution by providing a comfortable home for convalescing patients who are disturbed by contact with the acutely insane. The total cost of this villa, including furnishings, is less than £115 per bed. A steady increase of private patients has been maintained, especially for Carnegie House.

During the year 29 and 40 per cent. of the cases admitted respectively from Forfarshire and Kincardineshire had a pronounced suicidal tendency. Dr. Havelock's observations reveal that certain parishes in these counties send a very high proportion of suicidal cases to the asylum, and that a possible explanation of this seems to be inherited predisposition.

We note with much satisfaction the managers have joined the Scottish Asylums Laboratory Scheme, and we heartily endorse Dr. Havelock's opinion as to this being an important step in the right direction. This laboratory has been doing much valuable work for the last few years, and it is worthy of, and requires the heartiest sustenance of, all in Scotland interested in obviating and curing insanity. The report is a full one, and things generally indicate efficient management.

Lancashire County.—Whittingham.—This report is full of detail. There is evidently an urgent necessity for increased accommodation. At the date of the Commissioner's visit there were only three vacant beds. The admissions were selected owing to the want of accommodation, beds being reserved for acute cases. The recovery rate was only about 26 per cent. of the admissions, and the death-rate—10·8 per cent.—was above the average. Phthisis was the cause of death in 28 per cent. of the cases, and general paralysis and pneumonia in 15 and 18 per cent. respectively. The percentage of phthisical cases is alarmingly high, and we hope the committee will do something towards stamping out this terrible disease, or at least towards reducing the number of cases. Overcrowding is a recognised cause, and such conditions, we regret to say, here exist. Dr. Perceval makes some sensible remarks on this subject. Only 27 per cent. of the patients are able to attend the entertainments because of the inadequacy of the recreation hall. This proportion is much too small. The social side of asylum life should be as fully developed as possible in the interests of the patients. Intemperance was responsible for ninety-six of the admissions, or 15 per cent. Dr. Perceval in his Report remarks that the more one sees of insanity the more the importance of heredity is forced upon one. "If people could be bred with as much care as horses no doubt many forms of insanity would become unknown." A view which is but too obviously borne out by facts.

Prestwich.—This report contains the usual statistical and economic tables. Here, also, we regret to see, the accommodation, which has been used to its utmost capacity, is in a congested state, beds having to be put in lobbies and other unsuitable places. The rule evidently obtains among asylum committees to delay too long in providing extra accommodation. "Sufficient unto the day is the evil thereof." The percentage of patients usefully employed is satisfactory, but that of the males should be increased if possible. The Commissioners on their visit rightly took exception to the plates and cups in some places, where they were of enamelled iron in a dilapidated condition. We would like to see this class of delf, for which there is no necessity, abolished altogether. We note with pleasure the establishment of a well-equipped pathological laboratory. The number of patients admitted was 448, of whom 107 had previous attacks. The recovery rate was over 41 per cent., and the death-rate only about 6 per cent. Alcohol was responsible for 30 per cent. of the admissions, and pneumonia and phthisis for 20 and 21 per cent. of the deaths respectively—all high percentages.

Berkshire County.—Overcrowding has been keenly felt here too, and as many as fifty patients have been in residence above the allotted number. Therefore, we are not surprised to learn that several cases of enteric and a severe epidemic of pneumonia occurred. The admissions were very unfavourable, 70 per cent. being hopelessly incurable in the opinion of the Medical Superintendent. Hereditary influence was ascertained in 26 per cent., but, notwithstanding these facts, the recovery rate was 38·28 per cent. The death-rate was abnormally high—12·84 per cent. There is no Commissioners' report appended. We would like to see this rectified in future. The dietary for patients is very monotonous and below the average. Individual tastes do not receive much consideration. Dr. Murdoch, in his report, which gives evidence of his desire to be up-to-date in the management, while referring to numerous changes in the staff, remarks, "Our extremely isolated position, with its dull surroundings is, however, the greatest drawback. Increased wages and indoor comforts fail to counteract this serious disadvantage." We would strongly recommend the system of providing houses and engaging married men as a trustworthy means of obtaining a stable and efficient staff.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 12th, 1902.

AT the Medical Society's meeting the subject of

TUMOURS OF THE SPINAL CORD

was further discussed. Hr. Jolly showed one that measured three centimetres in its long axis, had a smooth surface, and was tolerably hard. Microscopically it was seen to be a pure fibroma. The tumour lay within the dura, and was separated from this as well as from the pia mater without cutting. The origin was probably in the perineural connective tissue. No nervous elements have so far been found in the growth.

At first he questioned the diagnosis, as it was impossible to prove a connection between the symptoms and a cycle accident that had occurred a year and a half before. It was possible that some functional disturbance was connected with it, but this was disproved when spastic symptoms appeared, associated with ankle clonus. Then appeared the possibility of tuberculous disease in connection with the injury. The negative effect of tuberculine injection and also the fact that extension made matters worse disproved this. The question as to whether the tumour was intra- or extra-spinal was doubtful even to the last, and the possiblity that it might be the former justified the undertaking of an operation.

Hr. Hahn had operated six times in the belief that a spinal tumour existed. In all cases the diagnosis had been correct, not only as to its existence but also as to the level at which it had been supposed to be placed, but in no case was the nature of the disease recognised with certainty. In two cases echinococci were present in the vertebral canal. One of the patients recovered, the other died. The third case showed pain in the spine and root symptoms. An operation revealed thickening of the vertebral arches, a kind of exostosis and nothing more. The patient recovered. In two cases there was no tumour, but a cavity formation in the cord, the one being syringomyelia, the other a cavity arising from softening. The last case was that of a patient who had had a stab with a knife ten years before, but who had been quite healthy in the meantime. At the operation a prominence was felt that could not be removed. At the autopsy a knife blade, 2 cm. in length, was found in the tenth dorsal vertebra. He had observed another case, but had not operated on it, which proved to be a metastasis of tubercle after removal of tuberculous glands. After his own experiences he might say that the prognosis was favourable and the diagnosis certain when distinct unilateral symptoms were present without pain in the vertebral column, and in the absence of fever.

Hr. Senator had lately had an old lady in his wards on whom an operation had been performed some years ago for carcinoma of the breast. She had then total motor paralysis of the legs, abolition of sensibility and pain with moreover bladder and bowel disturbances. The whole vertebral column was extraordinarily painful to the touch, and on any movement of the body. The autopsy showed an extradural tumour.

Hr. Remak related a case in which at the operation the tumour was found much more extensive than had been believed. It was the case of a lady, æt. 20, who had suffered for several months from severe sciatica, in which no therapeutic measures afforded the least relief, and where symptoms of paralysis had gradually come on. There was paralysis of the muscles of the left buttocks, partial paralysis of the left peroneus, severe pain in the left leg, with disturbance of sensibility of the external parts of the leg. There was slight bladder disturbance. The sacrum was very sensitive. The question was whether there was a tumour of the cauda equina or one in the region of the third to fourth lumbar roots.

He advised an operation, which, after some delay, was performed by Hr. Krause two months afterwards. The clinical condition here remained practically unchanged. First the fifth lumbar arch was removed, and soon a tumour projected that lay within the dura. The upper sacral vertebra and the arches of the third and fourth lumbar vertebræ were then removed, but the upper end of the tumour was not reached, and the operator desisted from going further as the patient could not bear any more extensive attempts. She died the night following. The autopsy revealed the tumour to be a sarcoma which reached in an upward direction above the swelling of the loins.

Hr. F. Krause remarked that in order to complete the operation he would have had to remove the broad arches of the lumbar vertebræ. The section showed that the tumour had reached four vertebræ higher, whilst the clinical symptoms, after careful examination, indicated the fourth or fifth as the upward limits.

Hr. Oppenheim would utter a warning as to exciting hopes from his two correctly diagnosed cases. Deceptions would arise in case of operative attempts. The absence of tenderness on pressure was not pathognomonic of spinal tumour; it was rather remarkable that the diagnosis in his two cases was correct, although the vertebral columns were not sensitive.

HEPATIC FEVER.

Dr. S. Rosenthal made this the subject of a "Festschrift" in connection with v. Leyden's commemoration. The paper is based on three cases observed by himself, and, after the report of the cases, he summarises his conclusions as follows:—Under certain circumstances at present not fully known, there are in connection with icteric hypertrophic cirrhosis and secondary atrophic liver, intermitting periods of fever which may last days, weeks, or months, interchanging with periods completely free from fever. These intermitting fevers generally come on in the afternoon or evening with or without a preliminary rigor of the quotidian type. Sometimes the type is inverse.

Quinine sometimes acts beneficially, but generally it fails. Arsenic is quite useless. Salicylate of soda is comparatively useful.

Frequent long periods of apyrexia occur, interrupted by a day's intercurring high temperature.

Besides the intermitting type the fever in some individual cases shows the remitting type.

The basis on which the fever rests is as little known as that of the fever of gall-stones. The presence or absence of jaundice is in neither case a deciding factor for the origination of the fever, which is probably of an infectious nature. Frequently-repeated punctures of the liver and spleen, with culture experiments on the most varied nutrient soils, have led to no positive results, neither bacterium coli nor other bacteria having been found. Examinations of the blood for plasmodia have also given negative results.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, July 12th, 1902.

Prostatic Hypertrophy.

Schlosser reported five cases of prostatic hypertrophy which he had treated by the Bottini-Frendenberg incision, in four of which the operation was successful, but one was a failure. He thought the operation was better than the sexual, or rather the unsexing operation.

Fungus.

Luksch reported a case where he took from the bronchi of a diabetic patient a fungoid growth never before recorded in the history of medicine. This aspergillus is peculiar to pigeons and hens, in which it is pathogenic and easily transmitted.

Tuberculosis.

Hueppe read a paper on our present knowledge of tuberculosis, first remarking that the disposition of the individual as well as the susceptibility of the particular organ were the primary factors to be considered in therapeutics and prophylaxis. To combat the disposition, Brehmer of Görhersdorf has adopted the diabetic treatment with considerable success.

Hueppe next attacked Koch's latest statement controverting the doctrine of the etiological identity of tuberculosis in man and cattle. He referred to his own experiments in conjunction with Fischl to prove the morphological identity in fowls, and how it differs in virulence until a particular stage is reached. He contends that the bacillus of cattle is the same as that found in man. In support of this assertion he mentioned that he had artificially produced lupus in man by injecting cow's milk containing bovine tubercle.

Epstein remarked that the disposition of each organ of the body depended also on the age of the individual. In the infant the bowel seemed to be the favourite nidus, in the juvenile the brain or lymphatics was most frequently the seat of the disease, while the lung was the favourite seat during puberty or in adult life.

Puerperal Metastasis.

Chiari related the history of a peculiar case of puerperal fever which recently came under his observation. The patient was æt. 28 at her fifth confinement, which was described as a normal parturition. On the fourteenth day a rigor with high temperature occurred, which brought her to the gynæcological department for relief. On examining the parts the uterus was found slightly enlarged with a fœtid lochia. A few days after admission the patient had to be transferred to the "interne" clinic, owing to a purulent inflammation in the left shoulder, probably metastatic. After this a general pyæmic condition supervened, followed a few days later by left pleurisy, the effusion being sero-purulent and containing streptococci.

Subsequently nephritis and pustular exanthema exhausted the patient, who died on the twenty-sixth day post-partum.

The post-mortem examination revealed pyæmic foci in all the parenchymatous portions of the internal organs with degenerative changes. The genitals showed no trace of injury, and were in fact quite normal.

The best explanation that can be given of this case is that its origin was septic endophlebitis at the union of the external iliac vein, and the internal where a thrombus two centimetres long was found filled with streptococci which were identical after cultivation with those found in the pus elsewhere. It is also fair to assume from the findings that the poison entered from the uterus by the left uterine vein, and this view is confirmed by the fœtid lochia.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

BRIDES-SALINS No. 2 (Savoy).

The medicinal treatment at Brides-les-Bains is principally by drinking. At the neighbouring establishment of Salins-Moutiers the external treatment greatly predominates; although in obstinate cases (where the mineral springs at Brides are not sufficiently purgative) the drinking of the Moutiers saline waters is added to the treatment at Brides.

The Salins-Moutiers springs supply over one and a half million gallons of saline mineral water every twenty-four hours. They rise on the right bank of the Doron (at the foot of a large chalk rock 25 ft. below the ground surface), through several fissures; are collected into two underground reservoirs, and are thence conveyed by canals to the bath establishment on the other side of the river. Their invariable temperature is 95° to 96° Fahr., and they have 2° Beaumé gravity. They contain 16 grammes of salt per litre, considerable chloride of sodium, soda, iron, iodine, arsenic and lithia, with much carbonic acid. Dr. Gubler, a very competent authority, affirms "they are the richest in chloride of sodium of any known waters." Drs. Blanc and Forestier (of Aix-les-Bains), in their report to the Savoy Committee of the Paris Exhibition in 1900, assert their superiority to any similar springs "in Spain, Italy, or even Germany High temperature, concentrated mineralisation, gas in solution, the enormous output per day, being characteristics which place them easily above other saline waters, and so assure to Salins-Moutiers a prosperous future."

These Moutiers Saline Waters have been well described as a "hot sea amidst the Alps," but, in addition to the qualities of the strongest of sea waters, they have the other valuable mineral constituents already named, and being warm, bubbling, and sparkling, are greatly beneficial to those debilitated by illness or suffering from weak lungs. Added to these advantages Salins-Moutiers has that of a situation at an altitude of over 1,400 feet above sea-level, and in the centre of a most picturesque and health-restoring mountain region.

The indications for Salins-Moutiers are all cases arising from atony, debility, rickety anæmia, defective nutrition and assimilation, lymphatism, scrofula, overgrowth, old fractures, dislocations, chronic arthritis and rheumatism, and especially feminine troubles. Writing in 1899, Professor George Buchanan testifies to the "great value of these waters for children of rachitic or scrofulous constitutions; for anæmia, chlorosis, and other debilitating conditions in women." The Moutiers waters are also used at Brides-Salins for heart diseases, as saline waters are at Nauheim.

Their combined mineral salts and carbonic acid render the Moutiers waters easy of digestion. According to Dr. Gubler they are *the sole* saline waters which can be drank in sufficient quantities to be really efficient, and yet be followed by no detrimental results.

A comfortable Hotel des Bains is attached to the bath establishment at Salins-Moutiers. Visitors, however, generally prefer to reside at Brides village, about two miles further up the Doron Valley, and at nearly 500 ft. higher altitude. The two stations are connected by electric tramway. At Brides are an English church and chaplain, a casino and daily concerts, French and English physicians, and half a dozen good hotels, the excellently managed Grand Hotel des Thermes and its annexes being in the same park as the baths, springs, and casino at Brides-les-Bains. For English visitors in search of a health resort "away from the madding crowd" and in the midst of most glorious surroundings, Brides-Salins reaches the ideal.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Operation for Simple Depressed Fracture of Skull with Coma in a Child.—**Mr. Battle** operated on a child, æt. 2 years 3 months, who had been admitted a few days before after a fall of 20 ft. from a window on to the pavement. The child had not recovered consciousness since the injury; her eyes were constantly rotated downwards and to the right; she moved the left arm and leg, but the right arm and leg did not respond to stimulus, and were rigid. A depressed fracture could be felt over and behind the left motor area. As the coma appeared to be deepening, it was considered best to trephine in the hopes that some clot might be found, the removal of which would relieve pressure on the cerebral substance. A semi-circular flap was raised and the skull trephined; the fracture was rather irregular, and there was not much depression. After the application of the trephine a small quantity of clot was exposed on the surface of the dura mater, but it was insufficient to account for the symptoms. The opening in the skull was considerably enlarged by means of bone forceps, then an incision was made through the dura mater; there was no blood clot on the surface of the brain, nor did the cerebral substance look bruised; there was, however, an immediate and rapid flow of cerebro-spinal fluid. It was not considered advisable to explore the brain, the symptoms being insufficiently localised to point to any one centre or connected group of centres. The flap was replaced, no attempt being made to restore the bone. A drainage tube was left in the wound in order that if any cerebro-spinal fluid continued to escape it might come away easily. Mr. Battle said that this was evidently a case in which there was probably contusion and laceration of the surface of the brain, in which the continued condition of coma was associated with excessive secretion of cerebro-spinal fluid, and possibly a progressive œdema of the brain in the neighbourhood of the injured portion. The depression of the skull was not regarded as a sufficient cause for the symptoms, the bone was not much depressed, and it extended over a fairly large area.

The result of the operation was very satisfactory, the patient being able to sit up in bed and take a penny with either hand within a week. For two days there was a discharge of cerebro-spinal fluid, and for some days the head was kept somewhat raised, and the child lying on her right side so as to gradually diminish the tendency to overflow from the wound. Mr. Battle said he considered the whole case interesting from the duration of the coma and from the rapidity of improvement after the operation. Bearing on the question of rapidity of recovery he mentioned a case that had been under his care some years ago: A boy who had been operated on for compound comminuted fracture of his frontal bone, suddenly developed coma with left hemiplegia about eight days afterwards. The patient was taken to the operating theatre, and without need for an anæsthetic the right side of the brain was explored in all directions with a trocar and cannula, but no abnormal condition was discovered. It was thought that his state was a hopeless one, but next day he had recovered consciousness and spirits, and when the house surgeon went round in the morning the patient insisted on sitting up in bed and shaking hands with him, and there was no trace of paralysis left, and he left the hospital a short time afterwards perfectly well.

TOTTENHAM HOSPITAL.

Abdominal Hysterotomy for Myoma. — **Dr. A. Giles** operated on a woman, æt. 31, who had been admitted on account of severe hæmorrhage. She had been married eighteen months but had had no children. On admission, the uterus was found considerably enlarged, and a diagnosis of intra-uterine myoma, probably becoming polypoid, was made. It was decided to endeavour to remove the myoma by the vaginal route, and the cervix was accordingly fully dilated. On introducing the finger it was found that the myoma was about the size of an orange and had a wide base of attachment, so that its removal from below would be a matter of great risk and difficulty; accordingly the abdomen was at once opened and a vertical incision was made through the posterior uterine wall; through this opening the myoma was removed, the uterine cavity being opened at the same time. The uterus was then closed in the same way as after a Cæsarean section with a series of interrupted mattress sutures passed deeply through the uterine wall and a continuous suture of fine silk approximating the peritoneal edges. The abdominal wound was then closed in the usual way. Dr. Giles said that the case was one specially suitable to this method of treatment; operation was urgently required on account of the excessive hæmorrhage, and when it was possible to remove the tumour and leave the uterus and appendages practically intact, the operation was an ideal conservative one. When a number of myomata were present, their removal leaving the uterus was a serious matter on account of hæmorrhage, and the mutilated uterus was not really worth leaving. With a single myoma, however, the tumour alone could be removed without additional risk, and a uterus was left that was capable of performing its natural functions; consequently the operation was specially indicated in the case of younger women. Any operation that involved the removal of a myomatous tumour without sacrificing the uterus might be described as a myomectomy; it was, however, convenient to reserve the term abdominal myomectomy for cases in which a subperitoneal pedunculated myoma was removed, an to use the term abdominal enucleation for cases in which a myoma was shelled out of the substance of the uterine walls. In contradistinction to these two procedures the method adopted in the present case, in which the uterine cavity was deliberately opened and a tumour removed from its interior, might be called abdominal hysterotomy for myoma.

BARMAIDS AND LEGISLATION.

The humanitarian instincts of the present age are happily to a great extent guided in rational grooves by the teachings of science. This tendency to link together the actions of heart and of head has been shown in no case more conspicuously than in the legislative control of labour, more especially in the case of the unhealthy and dangerous trades. The hours of work have been shortened, the principle of compensation for injury established, and trade processes so modified as to secure a far greater measure of safety to the health and the life of the workpeople. The scope of the Factory and Workshops Acts has been extended by degrees so as to include many trades, but there yet remains a wide margin of preventible trade mischief uncontrolled by the State. For instance, many trades which employ great numbers of workpeople, such as breweries and warehouses, often escape altogether from the control of the Acts on purely technical grounds. By an absurd provision of the Act a workshop is not controlled unless more than forty persons are employed therein, as if one should say that twenty persons might be poisoned but not fifty. Clearly the workers in all trades require protection against insanitary and structurally unsafe premises, against excessive hours of labour, regardless of the numbers who may be brought together under one roof. There are certain classes of labour, chiefly unskilled, which by their nature are extremely difficult to protect, and which are at the same time unable to protect themselves by a trade organisation of their own. As instances may be cited dock labourers, clerks, domestic servants and public-house servants. It is true that dock labourers have plucked up heart of grace of recent years, and by the formation of trade unions have greatly ameliorated their lot as regards pay and hours of labour. Recently Government has included laundry workers within the provisions of the Factory and Workshops Acts. That step recognised the duty of the State to protect the labourers in an occupation that may be called unskilled and is certainly far from wholesome. Laundry workers, before the passing of special factory legislation, were often obliged to work for an excessive number of hours under most insanitary conditions. Now that is all changed, and the metamorphosis makes us more hopeful that a similar meed of protection will be extended to public-house servants. Barmaids have often been called white slaves, and the term is one that in many cases simply registers a stern fact in appropriate language. The hours of work that barmaids are commonly called upon to perform are simply a scandalous reproach to any so-called Christian community. In addition, the food is often bad, no proper meal times are provided, the sleeping accommodation is insanitary, and holidays are practically unknown. It is no wonder that the years of a barmaid's life are short and that only women in the first flush of youth can withstand the strain of one of the most unwholesome of all occupations. Not long ago Glasgow did good service to the nation by calling public attention to the evils of the barmaid's life, both from a moral and a physical point of view. To her honour be it said that Glasgow has put an end to the employment of barmaids save under conditions that bring the occupation within the category of a tolerably wholesome calling. Were legislators to pay more attention to crying abuses going on within the four walls of the United Kingdom there would be no need to unfurl the Imperialist banner and go to the succour of people in far-off climes. We assert that the surroundings of the public-house reduce the occupation of a barmaid under average conditions to a short fitful existence of a few years, which is fatal to health and happiness. A Parliamentary inquiry into the condition of public-house servants generally would be of more practical importance to the innermost vitality of the nation than a score of wars, petty or great, waged in the interests' of comparative or utter strangers. The true Imperialism of the earnest Anglo-Saxon strain concerns itself with the welfare of the people here at home, however humble their lot and however helpless they may be to defend themselves.

THE TREATMENT OF TYPHOID FEVER.

There are certain diseases that seem ever to be in the experimental stage of treatment. An evidence not alone of the restless nature of the physician of to-day, but also of the progress of scientific knowledge. Of this latter class is typhoid fever, a disease which exemplifies in a peculiar manner the prevalent theories of disease. To-day we recognise that it is due to a toxin that shows a marked predilection for the adenoid tissues of the small intestines, as strychnine and other such poisons do for the muscle tissue. In typhoid the toxic products of Eberth's bacillus are as clearly recognised by their effects as are effects of eloterium or pilocarpine. But how does the toxin producing bacillus gain entrance to the body. In the pre-bacteriological days the text-books told of the poisonous vapours of decomposing products absorbed through the pulmonary air-cells. We then found the ground shifted and adapted to meet what was considered the requirements of the discovery of the bacillus. The alimentary canal was discovered to be the site of infection, and the introduction of the bacillus was accounted for by want of proper cleanliness—the soiled apparatus and stained linen not having been removed prior to their being dried up, and as such becoming sources of infection. Withal some physicians were not satisfied with all this explanation, and a diligent search commenced for the primary colony of the germ of the disease, and naturally enough an endeavour to attenuate or destroy it. From these researches Dr. Wasdin concludes that the primary germ colony of disease cannot be considered as occurring in the intestinal canal, but to be normally located in the respiratory tract—a theory which recalls that of the past, and one which in part accounts for the rare case of typhoid in which the clinical symptoms without the normal pathological conditions are not present. According to Dr. Wasdin's report, the bacillus toxin from the blood current gives rise to all the well-known terminal expressions: infection of the intestinal canal, the serous membranes, the bone marrow, and so forth. To reach the affected area in the lung an atomised solution of acetozone is used, and the same drug is given in capsules three times a day. When the temperature threatens to be dangerously high, cold sponging is recommended. The good effect of the treatment is stated to be marked from the first by an increased secretion by the kidneys, a decided lessening of the malodorous character of the stools, and a distinct lessening of the number of the stools, which become sterile. By the combined action of the oral administration of the drug, and its inhalation as an atomised or cloud fluid, the advocates of the therapy claim that they reduce the possibility of gaseous fermentation and its concomitants, hæmorrhage and perforation, and at the same time the destruction of the secondary infection of the canal by the typhoid organism, thereby averting further toxæmia by absorption from the alimentary canal. The germicide is therefore to be directed against both the primary colony in the respiratory tract and the secondary expression in the alimentary canal. The benzoyl-acetyl-peroxide, which has long been known as benzozone, the antiseptic used by Dr. Wasdin, is a non-poisonous product of the aromatic series, prepared from benzoleic acid. The antiseptic and non-poisonous properties of the chemical are well known, and its use in toxæmias can be tentatively recommended. The treatment attacks the disease on an entirely new principle, the theory of which has much to commend it, not the least of which is the innocuous character of the therapeutic agent employed.

MASTOIDITIS.

Sir William Wilde is to-day remembered more as a literary man than as a surgeon. We think of him as the author of the "Valley of the Boyne," whose archæological wealth of information and beauty of description has brought travellers to Meath from every civilised country. Withal he did good work in surgery, and his pamphlet, "Practical Observations on Aural Surgery," was a bold advance in the treatment of mastoiditis and inflammatory diseases of the middle ear. It is almost sixty years since he practised his incision through the compact tissue of the mastoid process and scraped away the carious tissue of the bone, plugging the cavity with lint. The very terms in which he described the operation have an archaic flavour. He was not the first to perform the operation, but he was the first to lay down rules for its performance and to give the symptoms that call for its being done. Riolanus, the surgeon to Henrietta Maria, performed the operation in 1649, some years after Harvey had demonstrated to him the circulation of the blood. But the folio edition of Riolanus gives no idea of the conditions that call for the operation, and his case was little more than a scraping away of diseased bone, without incision of compact osseous tissue. By an accidental syringing of carious disease of the mastoid Valsalva made the important discovery that he could wash out the middle ear from the mastoid cells. Jasser, a surgeon in the service of Frederick the Great of Prussia, made a similar discovery, and continued syringing the ear through the mastoid until he had cleared both the middle ear and the Eustachian tube. J. L. Petit, in his "Maladies des Os," refers to the treatment of mastoiditis, and the operation had a chance of being adopted when Proet had the misfortune in 1791 of exciting meningitis by the operation, and the same year Kolpin, operating on Baron von Beyer, physician to Christian VII., of

Denmark, met with the same misfortune. In this condition of doubt and dread, Wilde found the path of safety and placed the operation on a scientific basis. The operation met with universal approval, and is to-day practised by all aurists either on Wilde's original lines or on modifications of them; and twenty years after the publication of Wilde's case Schwartze published a record of 100 operations with 74 per cent. of successes. The operation became so generally performed that Politzer found it necessary to inculcate caution in its performance, and laid down a series of statements which the aurist should make to the patient and his friends to protect himself from blame should death result. We recall these to memory, for a Cuban medical journal has lately published a case in which, during the curettage of the carious bone the middle fossa of the cranium was opened, and one of the lateral sinuses wounded. The skill of the operator was taxed to the utmost to prevent a fatal issue, in which, however, he happily succeeded. Such accidents are unavoidable, and it is difficult to form an opinion on their probability of occurrence. It may be said that in long-standing disease they are more likely to occur than in others; but it must be borne in mind that the structure of the mastoid process is very different in many subjects. As a rule, the antrum mastoideum is connected with the pneumatic cells of the process by lacunæ, but often enough by only a narrow canal. Indeed, it has been well said that one mastoid process scarcely ever corresponds with another.

Notes on Current Topics.

Zymotic Curves of June.

The vital statistics of London for the month of June furnish abundant material of interest to the sanitarian. Small-pox has fallen steadily in accordance with its usual summer minimum, so that the Asylums hospitals contained only 837 small-pox patients at the end of June, as against 1,526, 1,442, and 1,273 at a corresponding period in the three preceding months. There were 99 deaths from small-pox, compared with 154 in May. With these figures before us it can hardly be hoped that the present outbreak will have exhausted its violence before the coming year brings round the period of its greatest intensity. Scarlet fever cases register the large seasonal intensity. Scarlet fever cases register the large number of 2,439, as against 2,113, 2,176, and 2,222 in preceding months; there were forty-three deaths from this cause. Diphtheria is still rife, and at the end of June 975 patients were under treatment for that disease in the Metropolitan Asylums Board hospitals; fifty-three deaths were due to that malady. The disease is following its usual curve, which places its lowest incidence in May and June; at the end of March the patients under treatment were 1,123; in April, 1,035; and in May, 960. Enteric fever cases, which should be at their minimum in June, showed an increase: 279 cases were notified, and 195 were under hospital treatment at the end of June, as against 121, 115, and 127 at the end of the three preceding months; there were twenty-nine deaths. These figures are far from satisfactory when the exact modern knowledge of the etiology of the disease is taken into consideration. Diarrhœa accounted for fifty-seven deaths, a number more than 100 below the decennial average. This result is gratifying, if we are to accept the view that the amount of diarrhœa forms a delicate register of its general sanitary condition. It is to be hoped that the rate of decrease will be maintained when the disorder attains its period of greatest mortality in the last week of July and the first fortnight of August. The highest numbers of deaths from specific infectious diseases were from the two unnotified maladies—measles, which accounted for 198, and whooping-cough for 151 deaths. The death-rate for the month was 13·9 per 1,000 living, and showed such variations as 6·7 in Hampstead, as against 19·3 in Finsbury and 19·9 in Southwark. Some approach towards equalisation of the death-rates in the constituent boroughs—that is to say, by way of reducing the mortality of poor and unhealthy districts—would speedily render London the envy of the world from a public health point of view.

The Cities of the Future.

In spite of the more general recognition of the importance of avoiding the features which render ancient cities so quaint and so unhygienic, municipal authorities in many instances continue to display a lamentable want of foresight in the laying out of new roads. No more striking example of wasted opportunities could be quoted than the way in which so many of the main roads leading out of London have been deprived for ever of their quasi-rural aspect, by permitting the erection of buildings far in advance of the building line. Thoroughfares that might have been spacious boulevards, have been converted into narrow sordid streets, and this without any corresponding advantage to the public. Dr. Fletcher Little, L.C.C., calls attention to a recent particularly flagrant instance of this want of foresight, a shortcoming which is disappointing on the part of such a progressive body as the London County Council. It is to be hoped that steps will be taken to bring public opinion to bear on this question in view of its important bearing on the future of our great cities.

A Medical Duel Averted.

A motion signed by the deputies of the North of France was recently presented to the French Chamber of Deputies on behalf of the Northern League against tuberculosis, in favour of the model of dispensary established by Dr. Calmette at Lille, which, it is thought, leaves nothing to be desired. Dr. Bonnet, of Paris, who claims priority in the conception of anti-tuberculous dispensaries, took offence at certain passages in this report and actually commissioned his friends, Drs. Muzy and Thibaut, to demand satisfaction of his *confrere* at Lille, who forthwith appointed Drs. Roux and Letulle his seconds.

The four gentlemen, having met and discussed the grounds of the challenge, came to the conclusion that the report contained nothing which could reasonably be construed as offensive to Dr. Bonnet, and there of course the matter ends. In spite of the traditional innocence of French duels the idea of two men, both enthusiastic advocates of a method of saving and prolonging human life, engaging in mortal combat is as incongruous as it is ridiculous. Incidentally the episode illustrates the foolish mania for priority which characterises many otherwise estimable and certainly talented persons. *Eh mon Dieu !* what does it matter who invented the thing if only it afford some protection against this most terrible of maladies? We trust these gentlemen will henceforth stand shoulder to shoulder as soldiers in the war against our invisible enemies, leaving quibbles such as these to occupy the attention of their intellectual inferiors.

The Diet in Advanced Life.

Theoretical considerations suggest, and practical experience confirms, the view that each decade of life has its special dietetic conditions. The infant organism cannot maintain itself in health on a diet which responds to the requirements of the adult, and it is equally certain that, with the advance of years modifications of the adult dietary are necessary if certain morbid contingencies are to be avoided. The elderly man automatically reduces his output of energy, and his tissues no longer utilise more than a limited amount of nutriment; consequently, if he maintains his dietary at the adult standard, there must result a disturbance of that physiological equilibrium which constitutes health at all ages. This principle, of course, does not preclude the liberal nourishment of the aged under special circumstances, but it entails the recognition of the axiom that the aged require less food than persons in the active period of adult life. Moreover, the diet of those advanced in years often requires to be considered not so much from the point of view of the amount that would be theoretically good for them, but of the possibility of their assimilating it. The wear and tear of life may have reduced the functional activity of their viscera so that they have become unequal to the digestion and assimilation even of the amount of food which normally they ought to take, and the measure of a healthy diet will have to be based on the functional activity of their organs; in other words, the limitation of food, though always necessary in the aged, will vary according to individual conditions.

Hansom Cab Reform.

The regrettable accident of which the Right Hon. Joseph Chamberlain was recently the victim may conceivably have for result to direct the ingenuity of inventors towards the designing of a vehicle which shall present the advantages of the present popular conveyance without its drawbacks—which are several and serious. Apart from the difficulty of entering a cab without appropriating some of the mud from the wheel, there is the *quasi*-certainty of being thrown on to the splash board or on to the road when, as so often happens, the horse stumbles or slips on the greasy asphalt or the slippery tram lines, rendered artificially dangerous by the frequent application of water to their polished surfaces. Then, too, there is the partial asphyxia which is speedily induced in rainy weather when the glass front is lowered, though this might easily be remedied by leaving a louvred opening in the side windows. Lastly, there is the really terrible risk of being thrown violently against, or through, the glass front in the event of the horse falling down, and this risk is the greater seeing that the rain which renders the protection necessary also tends to diminish the horse's foothold on the pavement. A Minister's life would not have been sacrificed in vain if his death by accident led to this much-needed reform, but we nevertheless congratulate ourselves and Mr. Chamberlain on the fact that his life has not been sacrificed on the altar of vehicular convenience.

Ethnology of Early Egypt.

The Edwards Professor of Egyptology in University College, who has been long and brilliantly enlightening the public in one of the most interesting and fascinating branches of human knowledge, unfolded a new vein recently in a paper which discusses the "Races of Early Egypt." Professor Petrie discusses the question from the new standing-ground offered by the discoveries of the past few years, in bringing to light the long-buried monuments of that very old civilisation. The learned writer discusses the physiognomy, craniology, anthropology, &c., of the portraiture of the early Egyptian, as so firmly depicted in their (approximately) imperishable lithic remains. Weapons, dress, hirsute decorations, &c., are also laid under contribution for items of knowledge. In opening the discussion of his materials, he points out and corrects one of the very common mistakes of the imperfectly educated reader. We must disabuse our minds of the prevalent feeling that stepping back a few thousand years will lead us to a simpler condition of races, and that at the present beginning of our information we deal with "purer" races than those around us in the present day. On the contrary, before man was tied down to the permanent possession of domestication and agriculture, he probably roamed and mingled more widely than in historic times. We must expect to deal with mixture of origin as much in 5000 B.C. as in 1900 A.D. He arranges his types of cranio-facial specimens of old Egyptian portraiture under seven heads: (1) The aquiline type, (2) the plaited-beard type, (3) the pointed-nose type, (4) the tilted-nose type, (5) the forward-beard type, (6) the straight-bridged type, (7) includes some examples of the mixed race of the Fourth Dynasty. Both in physiognomy and decoration Professor Petrie recognises a strong resemblance between the prehistoric Egyptian and the present Kabyle of Algiers.

Vegetarianism and Sunstroke.

LIKE most other eccentric cults, that of vegetarianism rests rather upon the emotions than upon the reasoning powers. An amusing instance of lack of logic on the part of a zealous disciple of that school has lately been published in one of the London daily newspapers. The correspondent in question, good, easy man, told the story of how for many hours he braved the heat of a midsummer sun without any covering to his head. The subsequent immunity from sunstroke he attributed to the fact of the coolness and purity of his blood, which was derived from strictly vegetable sources. If meat eating were the great predisposing factor in sunstroke, then a vast proportion of mankind would be laid low by the rays of the sun. Vegetarians, like teetotallers, usually try to prove too much. No one will dispute the fact that a man can live without eating flesh or drinking alcohol. On the other hand, many men who are moderate consumers both of meat and of alcohol live to a hundred years or more. So far as we know no one has ever yet proved that total abstainers either from flesh or from strong drink live on the average longer than the average Philistine who does not shun the flesh pots and the wine jars. Length of life is, on the whole, a pretty fair criterion of the harmlessness or otherwise of any habitual article of diet. Of course, as every medical man knows nowadays "sunstroke" is due to a specific microbial infection. The rash vegetarian who jumped at his conclusion anent that malady is not an uncommon type of witless reasoner where medical matters are concerned. Hence the prosperity of modern quacks and quackery.

Cider as a Summer Beverage.

THE wholesomeness of cider is fairly well accepted among medical men, at any rate among that tolerably large majority of the profession which does not fix the stamp of disapproval upon the moderate consumption of alcoholic liquors. Like beer, cider varies greatly in its flavours and in its alcoholic strength. The sweet ciders of Hereford, Norfolk and Worcestershire stand out in strong contrast from the rough, strong and somewhat acrid ciders of Somerset and Dorset. When properly fined and made from ripe fruit of choice stock, dry, sparkling cider is, in the opinion of not a few connoisseurs, almost equal to the choicest brands of champagne in flavour and vastly less detrimental to health. It has a decided advantage over the vineyard wine in point of cost, as cider is a comparatively cheap beverage. Moreover, it is not, like beer and champagne, bad for gouty persons. The malic acid of cider, indeed, is said to exercise a solvent action upon uric acid, and whether that be the case or not, cider certainly does not appear to produce gout in those who habitually drink it. Cider is, speaking generally, a lighter drink than ale, and is better adapted for use in summer weather. It is mildly laxative, and this is of importance. When skilfully mixed there can be no finer cup than that made with cider and soda-water, flavoured with lemon and a pinch of spice, fortified with a dash of liqueur, sweetened with a little sugar, cooled with ice, and garnished with a slice of cucumber and a sprig of borage. With such a reminiscence in mind it is comforting to hear that of late years a great revival has taken place in the cider-making industries of England.

Post-Graduate Instruction.

THE number of the New York *Medical Record* for June 21st contains an excellent synopsis of the facilities for post-graduate instruction provided in the principal European countries and in the United States, the compilation whereof must have required much trouble. We gather that, except in one respect, the post-graduate institutions of the United States are to be regarded as unsurpassed, the exception being instruction in tropical diseases, a subject in which Americans are as closely interested as we are ourselves. No doubt this lapsus will shortly be remedied, and then medical men from over the ocean will be enabled to obtain such instruction as they require at home without undertaking expensive journeys to one or other of the capitals of Europe. The merit of first organising post-graduate instruction belongs to the States, no doubt because the perfunctory training exacted of their students at many transatlantic medical schools leaves so many gaps to be filled in after life. It says much for the conscientiousness of the American neo-practitioner that he recognises his shortcomings and does his best to make them good. It is gradually dawning on practitioners on this side that they too have not learned all that there is to be known during the brief period covered by the curriculum, and a healthy stimulus has thus been given to further study, which is finding expression in the multiplication of post-graduate centres.

Alleged Ill-Treatment of an Asylum Patient.

AN abortive prosecution by the Commissioners in Lunacy was recently heard before the Carmarthen borough magistrates, in which a young woman, formerly a nurse at the Joint Counties Asylum, was charged with ill-treating a patient by striking her with a broom. Dr. Alice Johnson, assistant medical officer at the asylum, the principal witness in the case, stated that she went into the dormitory, in which there were over fifty patients, and saw the nurse in question striking the patient, who was in bed covered with bedclothes, across the legs with a broom; on remonstrating with her, she replied that she had no intention of hurting the patient, but simply intended to frighten her because she was very noisy, and making the other patients restless. Dr. Johnson also stated that the blows were delivered with no force whatever, and that she afterwards examined the patient three times and found no marks on her. On the case being reported to Dr. Goodall, the medical superintendent, he informed the nurse that it was necessary in the interests of the discipline of the institution that she should leave, and that he would have to discharge her summarily. He also told her that he was aware of her good conduct and previous good record; that he was sorry for what had occurred. He reported the dismissal to the Lunacy Commissioners in the usual course, and expressed to them his opinion that it was not a case for prosecution, but notwithstanding they instituted those proceedings. It seems hard to realise why, for there is really no evidence of ill-treatment, although we strongly disapprove her novel method of repression; she had been eleven months in the asylum, was kind and considerate to the patients, and we think the punishment meted out to her by the superintendent was sufficient for her indiscretion. Dr. Goodall was certainly in the best position to measure out the punishment which fitted the crime, and, whilst admitting the humane feelings which prompted the Commissioners, we regret such an action should have been brought, and are glad the Bench dismissed the charge without retiring.

A Would-be Royal Cinematographist.

The Paris *Figaro* relates an amusing (and probably apocryphal) story concerning an enterprising cinematographist who is stated to have gone to Buckingham Palace as soon as the imminence of an operation became known, for the purpose of photographing the various steps of the operation. The surgeons were taken by surprise and took him for a lunatic, but as he was fortified with excellent credentials, backed by a well-known name, they condescended to explain to him that such a proceeding *a la Doyen* was quite inadmissible in this country. Nothing daunted, the applicant offered to be satisfied if the surgeons would go through the similitude of the operation on one of his assistants, the *mise en scène* being suitably arranged, offering at the same time what he considered ample remuneration. At the mention of remuneration the surgeons took umbrage and had the intruder expelled. There are too many elements of improbability in this *racontar* for us to accord it the slightest credence, but it is, after all, not one whit more absurd than many of the rumours which have passed current for news during the last fortnight.

Hydramnios Diagnosed as Ovarian Cyst.

A woman was recently sent into a metropolitan hospital for the removal of a large ovarian cyst. The possibility of pregnancy was excluded by the general practitioner under whose care the patient had been, and the symptoms generally pointed strongly in favour of his diagnosis. Operative measures having been decided upon, the cyst was exposed by an abdominal incision and a large quantity of watery fluid withdrawn by the aid of a trocar. On enlarging the incision a small six-months' fœtus presented at the aperture, and another was found lying within the much-dilated uterus, for such it turned out to be. The result was somewhat disconcerting, but the wound in the uterine wall was sutured and the abdominal wound closed, and the patient is progressing favourably. This case, which will, no doubt, be published in full later on, is highly instructive, as showing how extremely difficult the differential diagnosis of ovarian cyst and hydramniotic pregnancy sometimes is.

Repeating Prescriptions.

An inquest in Margate by the borough coroner on the body of an inebriate brings forcibly before the medical profession and the public the dangers of repeating prescriptions. The last victim was a man, æt. 41, who, on Sunday, the 15th ult., drank a sleeping draught of bromine, chloral, and morphia, and died in his sleep. Two years previously he had been attended for incipient delirium tremens, and his medical attendant took the precaution of administering each dose of the medicine himself, until it took effect and then brought away the remainder of the mixture. This time the poor inebriate took the prescription to a pharmaceutical chemist and had it compounded, and took too much of it and died. The compounder was quite within his legal right in preparing the two-year-old prescription; but he certainly would have shown more consideration for both his customer and the prescriber if he declined to compound a two-year-old prescription containing a large number of big doses of such powerful and lethal drugs as morphia and chloral until he had consulted the prescriber. In our experience such has been the rule in first-class compounding houses. Withal the fact remains that a pharmaceutical chemist may compound any prescription as often as the patient brings it, or for that matter for any person who brings it. The majority of our readers know that prescriptions are lent about freely, and there is no trouble in getting them filled. We look on this state of affairs as a public danger, one which, however, the prescriber can remedy to a certain extent by writing across his prescription the words, "this prescription is not to be repeated." If so marked it cannot be repeated legally, and if any unpleasant effect resulted from its repetition the compounder would find himself in an awkward predicament. We, however, think that the Council of the Pharmaceutical Society might bring before their members and the holders of their licences the advisability of not repeating old prescriptions containing abnormal doses of lethal drugs, and pharmaceutical chemists might bring before physicians the necessity for marking on all unusual prescriptions for highly toxic remedies "not to be repeated."

The Sterilisation of Salads.

The consumption of uncooked vegetables and fruit undoubtedly entails a risk of typhoid and other infections *via* the stomach, and on several occasions epidemics of diarrhœa, cholera, and enteric fever have been traced to particular deliveries of food stuffs of this class. An Italian observer points out that spraying with a 2 per cent. aqueous solution of tartaric acid is rapidly fatal to most pathogenic micro-organisms including that of Asiatic cholera. Immersion of raw vegetables in a 3 per cent. solution of the acid was shown experimentally to completely sterilise artificially infected vegetables without injuriously affecting their taste, provided of course that they are thoroughly washed before being eaten. The suggestion may prove of value, although it does not afford any protection against germs contained within the sap vessels of the plant as, for instance, in plants grown on sewage farms. The plant structures, it is true, ultimately destroy pathogenic and other bacilli, but this process of vital sterilisation does not take place until assimilation is far advanced, consequently the stem may contain large numbers of undigested, and therefore still active, bacilli. This risk may be minimised by discarding the stems when preparing salads, but nothing short of boiling can be relied upon to provide absolute safety against infection. The moral is that in epidemic seasons and countries the use of uncooked vegetables should be avoided, though an exception may be made in favour of raw fruit which is not undergoing decomposition, provided that it be carefully washed in pure water.

Cancer of the Appendix.

At the recent meeting of the American Medical Association, Dr. Harte, of Philadelphia, brought forward the subject of cancer of the vermiform appendix, of which two cases had come under his own observation, both, curiously enough, in persons about 25 years of age. The history is that of an ordinary recurring appendicitis, and the diagnosis of malignancy can hardly be made without an exploratory incision. He surmised that the occurrence of malignant neoplasms in this situation is more frequent than is usually supposed, basing his conclusion on the fact that the more careful examination of removed appendices during the last few years has resulted in a considerable addition to the number of such cases on record. Several others were reported by those who joined in the discussion on the paper, including one case in a woman of 40 and another in a man of 80. On the other hand, Dr. Matas, of New Orleans, stated that he had never met with an instance of cancer of the appendix in a thousand cases carefully examined by him when demonstrator of anatomy (1885 to 1895). Inasmuch as the existence of a chronic irritation or inflammation of tissues is known to favour the subsequent development of malignant growth, it may be assumed that the appendix, so commonly the seat of the predisposing irritation, would be more exposed to take on cancerous degeneration than certain other important anatomical structures.

The Pathological Significance of Psoriasis.

Psoriasis is a common disease of the skin, but in reality we know very little concerning its etiology and pathological significance. In the last number of the *Polyclinic* an appeal is made to practitioners to follow up the history of their cases of psoriasis in order to discover what becomes of them, that is to say, whether they live to old age, or are liable to intercurrent diseases which shorten life, with special reference to cancer. There is more in this note of interrogation than meets the eye, for underlying it is a manifest desire to elicit another argument in favour of the view that arsenic is a predisposing cause of cancer. It must be admitted that if it could be shown that psoriasis was followed by cancer in an exceptional proportion of the cases there would be some ground for incriminating the administration of arsenic, since virtually all such patients, at some time or another, undergo a course of treatment by arsenic, often for long periods. Unfortunately the counter-demonstration, *e.g.*, the proof that psoriasis is not followed by cancer in more than normal proportion in the absence of any arsenical treatment, must be almost impossible to obtain, at any rate until this reiterated suggestion of the malignant action of arsenic has had time to create a prejudice against the drug in the minds of the public. Perhaps Mr. Hutchinson may be able to tell us whether workers in arsenic figure unduly on the cancer roll and why cancer has increased since the disfranchisement of arsenicated wall papers, once so common.

Phthisis in the Metropolis,

In the recently issued returns of the Registrar-General for 1901 it is shown that phthisis was the assigned cause of 7,735 deaths in London last year, against a corrected annual average of 8,291 deaths in the ten years 1891-1900. The phthisis death-rate was equal to 1·71 per 1,000 as compared with 1·90 and 1·79 in the two preceding years. But in the case of several of the metropolitan boroughs it is necessary to carefully distribute the institution deaths from phthisis, in order to arrive at a fairly reliable measure of local mortality from that disease. Thus, for example, in Kensington, which borough contains the St. Marylebone Infirmary and a part of the Brompton Consumptive Hospital, 426 deaths from phthisis were registered during the year, but it was found, after distribution of institution deaths, that only 241 deaths from phthisis properly belonged to Kensington; the death-rate in this borough from phthisis was thus reduced from 2·42 per 1,000 to 1.37. Last year, after proper distribution, the phthisis death-rates in the metropolitan boroughs ranged from 0·90 per 1,000 in Lewisham, 0·91 in Hampstead, and 1·10 in Paddington to 2·29 in the City of London, 2·51 in Southwark, and 2·81 in Holborn.

Is a Disregistered Man a Medical Practitioner?

The other day we had occasion to refer to the case of a man in the provinces holding an American medical diploma, but of course unregistered, who was fined for non-compliance with the compulsory notification of infectious diseases law, and we commented on the anomaly of his being proceeded against for failing to discharge a duty imposed presumably only upon qualified and registered medical practitioners. Mr. Thomas Richard Allinson, ex-L.R.C.P., has raised the question afresh, and was fined last week for failing to notify two cases of small-pox. Mr. Allinson frankly admitted that he omitted to notify simply in order that the sufferers should not be removed to hospital, thereby greatly aggravating any offence that he may have committed. But Mr. Allinson, in the eyes of the law, is no longer a medical practitioner, and under these circumstances it is difficult to understand how he can be brought under the penal clauses of the Act. The head of the family is the proper person to be proceeded against, and in this instance we are pleased to see that he also was sentenced to a fine, small in amount it is true, but still a fine. These occurrences give prominence to the chaotic state of the legislation regulating the practice of medicine in this country. The law as it stands affords the public absolutely no protection against ignorance or quackery, and the fact of a man's having been struck off the *Register* does not appear to entail any particular drawback or to confer any corresponding immunity.

Lachnanthes Tinctoria.

Dr. Latham, of Cambridge, is pursuing his wild-goose chase after the merits of the drug which, on far too slender grounds, has been prerecognised as a remedy for consumption by Mr. Alabone. He finds that it is a powerful drug, in the sense that in small doses it kills guinea-pigs, death being preceded by paralysis of the extremities. This information, however, is *ultra vires*, since the slaughter of guinea-pigs is not the reason for which it has been so mightily boomed, and there are many simpler ways of relieving these small rodents of the *tædium vitæ*. Incidentally it is stated that lachnanthes does not delay, but rather hastens, the fatal termination of tuberculosis in animals. We are promised further investigations of a more purely therapeutical kind, and there is no obvious objection to their being made except that they tend to encourage the hope that consumption is a disease that may be cured by drugs, which is an hypothesis at variance with all we know of this dread malady. We cannot help thinking that Dr. Latham might have more usefully occupied his leisure than in an investigation foredoomed to failure, unless, indeed, success is to be measured by the certainty with which the worthlessness of the drug is demonstrated.

Small-pox at Swansea.

There can be no longer any doubt that the outbreak of small-pox has reached dangerous dimensions. On July 12th the Lord Chancellor took the extreme step of transferring the forthcoming county assize from Swansea to Cardiff. That decision was communicated to the Under-Sheriff of Glamorganshire by Justices Ridley and Jelf. This state of affairs in a crowded centre of population in South Wales cannot be regarded otherwise than in the light of a great calamity. It is the more alarming inasmuch as the present month should register the minimum of an outbreak of small-pox. It may be safely concluded that the Lord Chancellor would not have dislocated the local assize system except under great pressure.

The Samaritan Free Hospital and Dr. Shaw-Mackenzie.

The New York *Medical Record* for June 28th contains a very fair and damning summary of the proceedings in virtue of which Dr. Shaw-Mackenzie, having been elected to a post on the staff of the Samaritan Free Hospital, was subsequently displaced, in violation of the most elementary rules of justice and fair dealing. The circumstances, which we need not recapitulate, reflect discredit upon the management of the institution in question, and incidentally upon the medical staff, who deliberately placed an honourable gentleman in a most painful position without the shadow of a reason, professional or social, to justify their conduct. We agree with our contemporary that "it is outrageous that a man's good name and reputation should be exposed to the accident of a vote or to the rallying of supporters of another candidate, and that he should be involved in litigation through the fault of the Committee." Such a case is fortunately unparalleled in the annals of hospital government.

PERSONAL.

Dr. Karl Gussenbauer, Professor of Surgical Pathology in the University of Vienna, has been elected Rector Magnificus for the ensuing academic year.

Professor Frank Billings, M.S., M.D., Professor of Medicine and Dean of the Faculty of Rush Medical College, has been elected President of the American Medical Association.

Sir W. T. Thiselton-Dyer, K.C.M.G., F.R.S., is the first President of the new Pharmacological Society which is to meet in the premises of the Society of Apothecaries, and which already numbers some fifty members.

Sir Frederick Treves on being made a baronet will be described as "Sir Frederick Treves of Dorchester," and Sir Francis Laking as "of Kensington," the reason being the desirability of avoiding confusion with possible baronets bearing similar names.

Professor Fournier, having attained the age limit, has resigned the Chair of Clinical Medicine at the Faculty of Medicine of Paris, which he has occupied for the last twenty-two years, and Professor Gaucher has been elected by the Faculty to succeed him, subject to the approval of the Minister of Public Education.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

Presentation to Dr. John Campbell, F.R.C.S.—On Monday, July 7th, an afternoon reception was held at the Samaritan Hospital, Belfast, when a large number of guests—including the leading medical men of the city—accepted the invitation of the Committee to be present. The object of the gathering was to witness a presentation to Dr. Campbell on the occasion of his marriage to Dr. Emily Fitzsimons, of Tralee, co. Kerry. The presentation took the form of a solid silver tea and coffee service and salver, which latter bore the following inscription:—"Presented, on the occasion of his marriage, to John Campbell, M.D., F.R.C.S.Eng., with a silver tea and coffee service, by the Committee, matron, and nurses of the Samaritan Hospital as a token of gratitude for his unfailing kindness and attention. June 25th, 1902." Sir James Musgrave, Bart., occupied the chair, and the address was read by Miss Florence Henderson, Hon. Sec. of the Ladies' Committee. The Lady Mayoress (Lady Dixon) made the presentation, and after Dr. Campbell's reply, Sir Wm. Whitla spoke, testifying to the universal esteem and respect in which Dr. Campbell is held by the medical profession.

THE SMALL-POX EPIDEMIC.—We seem to have got rid of this trouble, for the present at any rate, as no new cases have appeared for about a month now. The net result of the scare has been an enormous increase in vaccination and revaccination, and the erection of a small-pox hospital at Purdysburn, about five miles from the centre of the town, and some 200 yards from Purdysburn Lunatic Asylum. This is near the site on which the permanent fever hospital for the town is to be erected, and is to serve as a temporary small-pox hospital till that is ready. The new structure is of corrugated iron, on a foundation of brick and cement. It has four main wards, each to accommodate eight patients, with kitchens, bathrooms with hot and cold water, &c.—all connected by a long covered passage with an administrative block, where doctors and nurses' rooms are situated. There are also wash-houses and a small destructor, so the whole arrangements seem complete. It was erected in less than three weeks, and nothing remains but for the happy ratepayers to pay the bill, which unfortunately cannot, in the present defective state of the law, be charged to the anti-vaccinationists.

Obituary.

JOHN CURNOW, M.D.LOND., F.R.C.P.

WE regret to have to announce the death of Dr. John Curnow, of Wimpole Street. Dr. Curnow was born at Towednack, near St. Ives, Cornwall, on January 26th, 1846, and was educated at Penzance and at Bath. He matriculated at King's College, London, in October, 1864; he became a member of the Royal College of Surgeons of England in 1868, and obtained his degree of Doctor of Medicine of the University of London in Nov. 1871. He was appointed house physician at King's College Hospital in 1869, at which hospital he was demonstrator of anatomy till 1870. He was appointed Gulstonian Lecturer of the Royal College of Physicians in 1879, and has held the post of Professor of Clinical Medicine at King's College since 1896. He was long associated with the editorial staff of the *Lancet*, and was the author of several important articles in Quain's "Dictionary of Medicine."

SENOR D. MATIAS NIETO SERRANO, MARQUES DE GUADALERZAS (Editor of *El Siglo Médico*).

IT is with regret that we announce the death of Señor Serrano, Marques de Guadalerzas, editor of *El Siglo Médico*, the doyen of the medical profession in Spain. He was a member of the Royal Academy of Medicine, and President of the Psyco biological Society of Spain. He was born on February 24th, 1813, and died on Thursday, July 3rd, 1902, at the ripe age of eighty-nine years. Of him, Don Decio Carlan writes:—He was a typically great man—virtuous, prudent, thoughtful, proud of his race, dear to his friends, and an honour to his family. He obtained many honours for his services to science and his country. For his services as a military surgeon he was awarded the Cross of Isabella the Catholic and the Cross of Charles III. By examination he became a Fellow of the Royal Academy of Medicine in 1839, and in 1861 was elected permanent secretary. After he retired from the military service he obtained the Grand Cross of Maria Christina and the Grand Cross of Isabella the Catholic. In 1875 he was elected as one of the Council of Instruction, and soon afterwards elected President of the Section of Surgery. He presided over the first Medical Congress held in Madrid in 1868, and finally was created Marques de Guadalerzas by the Queen Regent.

He wrote a good many medical articles, and of these the most interesting were his medical reminiscences which appeared in *El Siglo Médico* under the title "Vejeces."

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

RETRO-PERITONEAL FATTY TUMOUR.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is an error in your report of the July meeting of the Obstetrical Society of London (THE MEDICAL PRESS AND CIRCULAR, July 9th, p. 35). In the paragraph on my specimen it is stated that "on the right side it was intimately connected with the kidney, which occupied a pelvic position, *and was removed with the tumour.*" I took care not to disturb the kidney, as there was no reason whatever why it should be removed, and I could not find any left kidney. I specially dwelt on the fact that lipomas of the omentum and lipomas of the uterine broad ligament are only pathologically retro-peritoneal, and can be removed with relative ease and safety, whilst large lipomas, like my specimen, behind the mesentery and posterior parietal peritoneum, are very dangerous to extirpate. In reply to Dr. Giles, I observed that retro-peritoneal tumours were possibly associated with some teratological condition of the kidney. In my case the right kidney lay on the brim of the pelvis, its vessels apparently arising from the common iliacs. In Billroth's case of fibroma of the broad ligament (No. 7 in my "Table of Cases of Fibroma of the Broad Ligament," "Trans. Obstet Soc." London, Vol. XLI., 1899, p. 188), an essentially retro-peritoneal form of growth, the left kidney and suprarenal capsule lay in the pelvis, and were removed with the tumour.

I am, Sir, yours truly,
ALBAN DORAN.

BAKEHOUSE LEGISLATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reading your valuable and interesting leader on "Bakehouse Legislation" (THE MEDICAL PRESS AND CIRCULAR, July 2nd), I observe the following paragraph:—"The key to the public health aspects of the case was given by Drs. Waldo and Walsh a few years ago, when they demonstrated that the interior of a loaf was not necessarily sterilised by baking." May I venture to point out that Drs. Waldo and Walsh demonstrated nothing of the sort, and, indeed, demonstrated nothing at all. I have seen these statements repeated over and over again in various daily and weekly papers, and one gets very tired of the repeated iteration of the thing that is not. But, after all, one does not expect the writers in the ordinary daily papers to concern themselves much about the validity of arguments or the nature of proof. In scientific journals, however, one has a right to expect something nearer approaching to scientific accuracy. One has only to read this much-quoted pamphlet of Drs. Waldo and Walsh to see that their experiments were entirely inconclusive. They simply showed that certain non-pathogenic germs were found in newly-baked bread. No attempt whatever was made to show that those germs had previously existed in the dough before it was baked. If the dough had been inoculated with certain germs, and if some of these germs could afterwards be traced in the newly-baked bread, there would have been something nearly approaching to the demonstration. But nothing of this sort was done, and the accepted belief that the temperature of the baker's oven is enough to sterilise dough is entirely unshaken by anything that Drs. Waldo and Walsh did.

It may further be pointed out that bread has, from time immemorial, been baked under the most insanitary conditions, particularly, as your leader indicates, in India, and yet there has never been any epidemic of any kind that can be properly traced to the consumption of such bread. These considerations will lead to the conclusion that bakehouse sanitation is not "vital to the welfare of the community at large," though it is undoubtedly of the utmost importance in the interests of the bakers' journeymen. That is the real and quite sufficient ground for a vigorous call for reform.

I am, Sir, yours truly,
Editor, The "Baker and Confectioner."
61, Chancery Lane, London,
July 10th, 1902.

[The experiments, in our opinion, were both logical and conclusive. They showed that bread taken from the centre of a newly-baked loaf—of course under careful precautions to prevent contamination by outside microbes—contained living germs. Surely that demonstrates the fact "that the interior of a loaf was not sterilised by baking." If the loaf had been sterilised throughout no micro-organisms could have been cultivated from the bread removed from the centre of the loaf. The loaf was not sterilised by baking, therefore organisms could be cultivated from it. The organisms were in the dough; where else could they have come from? The conditions of life of pathogenic or non-pathogenic bacteria are similar. Hence it is reasonable to assume that if non-pathogenic germs survive baking pathogenic germs will do likewise. The danger arises from the sort of microbes to which the flour and dough are exposed in the insanitary bakehouse. We consider from a scientific point of view Drs. Waldo and Walsh proved their case up to the hilt.—Editor, Medical Press and Circular.]

Literature.

CLINICAL LECTURES ON HYDATID DISEASE OF THE LUNGS. (*a*)

This excellent monograph is the outcome of a series of lectures delivered at the Adelaide Children's Hospital. Hydatid disease of the lung is by no means common in this country and is one of the rarest of pulmonary affections. It is well, therefore, that Dr. Lendon should have availed himself of the opportunities which clinical study in Australia affords of furnishing the profession with a concise, practical and yet thoroughly scientific presentation of the subject. It is intended for students and practitioners, and by its style, arrangement, and clear instructions should prove of much service to medical men practising in the Commonwealth and may be read with interest and profit even by practitioners in this conservative country.

In ordinary text-books but little space is given to hydatid disease of the lungs, and, as it is long since the works of Dr. Dougan Bird and Dr. Davies Thomas appeared, Dr. Lendon's monograph is particularly welcome.

The author conveniently deals with his subject as it presents clinically in various stages. First, the unruptured cyst is considered; the period of latency is marked by an absence of symptoms or by indecisive symptoms, and may even end in retrogression; usually, however, marked physical signs sooner or later give rise to the suspicion that hydatid disease exists. When rupture of the cyst occurs death may follow rapidly from the flooding of the lungs with fluid, or suffocation may result from blocking of the larynx with a piece of hydatid membrane or with a daughter cyst. The rupture of the cyst may be followed by a period of quiescence, the cyst becoming obsolescent, or there may be expectoration of the mother cyst, or sepsis may occur. But even when expulsion of the hydatid membrane has been accomplished it must not be forgotten that there still remains the empty lung cavity which must be dealt with.

Dr. Lendon's work is rendered peculiarly valuable by the faithful record of cases which have come under his observation. His suggestions for treatment are sound, and, while full of common-sense, are based on well-ascertained pathological and clinical data. Not only are intra-pulmonary cysts fully dealt with, but the question of cysts in the pleural cavity is considered, and a short section is devoted to the subject of the invasion of the thorax by cysts of abdominal origin.

The subject is in many ways special, and we regret that it is impossible, in the short space at our disposal, to give any adequate idea of the ground covered by Dr. Lendon, but we have no hesitation in recommending the work to our Australian *confrères;* and, at a time when the interests of one part of the Empire should be considered the interests of all, we commend this modest little work to the profession generally.

THOMSON ON ACUTE DILATATION OF THE STOMACH. (*a*).

This short monograph has grown out of a paper read before the Royal Medical and Chirurgical Society. It is a concise and practical summary of the chief characteristics of acute gastrectasis. The histories of five cases are given at length, and useful summaries of thirty-nine others collected from medical literature. With these as a basis the subject is ably discussed, and, although Dr. Thomson has not succeeded in throwing any new light on the perplexities which surround the pathology of acute dilatation of the stomach, he has nevertheless furnished one of the best presentations of what is thought and known.

His division, although arbitrary, is suggestive. He arranges the already recorded cases into five groups: those in which the dilatation occurred without any apparent cause, and in which after death no other lesion was found; those in which after death some definite lesion has been found; those in which the dilatation has followed some surgical operation, and in which, after death, no other lesion has been found; those in which dilatation has apparently followed some indiscretion in diet; and those in which dilatation has followed an injury.

The symptoms and physical signs are briefly presented, and the post-mortem appearances are well illustrated by photographs. The longest and most valuable section of the work is devoted to a discussion of the pathology, which, we fear, must still be left in much obscurity. The suggestions regarding treatment are short but sensible.

The whole monograph is worthy of careful perusal and will be of service as affording a convenient source for reference; but why did not the author complete his book by supplying a bibliography and an index?

THE MILROY LECTURES. (*b*)

This interesting volume really consists of three parts—the Milroy Lectures for 1899, various addresses delivered before the Royal Medical and Chirurgical Society, and several essays on hygienic matters.

Dr. Vivian Poore is a firm believer in the wisdom of

(*a*) "Clinical Lectures on Hydatid Disease of the Lungs." By Alfred Austin Lendon, M.D., Lecturer on Obstetrics and Clinical Lecturer on Diseases of Children in the University of Adelaide, &c. Pp. 122, with 3 Plates and 14 Figures. London: Baillière, Tindall and Cox. 1902. Price 5s.

(*a*) "Acute Dilatation of the Stomach." By H. Campbell Thomson, M.D., M.R.C.P., Assistant Physician to the Middlesex Hospital; Medical Tutor in the Medical School. Pp. 54, with four figures. London: Baillière, Tindall and Cox. 1902. Price 3s.

(*b*) "The Earth in Relation to the Preservation and Destruction of Contagia: being the Milroy Lectures delivered at the Royal College of Physicians in 1899, together with other Papers on Sanitation." By George Vivian Poore, M.D., F.R.C.P., Professor of the Principles and Practice of Medicine, University College, London, Physician to University College Hospital, &c. Pp. 257, with 13 Illustrations. London: Longmans, Green and Co. 1902.

the old saying: "The rain to the river, the sewage to the soil." He contends that the dangers of applying dung to the soil are as nothing in comparison with its advantages. He finds no evidence that contagia spread in the soil. "To live in filth and to inhale the products of putrefaction given off from privies, or pails of fæces or sodden ground, results in disease, but there is no evidence whatever that disease thus generated is able to spread through the soil and infect a neighbouring house or street." On financial as well as hygienic grounds Dr. Poore would advocate a "return to the soil." He certainly shows that our present methods are wasteful and unnatural and lead to municipal and national impoverishment. The sections dealing with the relation of the soil to such diseases as tetanus, anthrax, dysentery, cholera, malaria, typhoid and other infectious diseases are somewhat superficial and too meagre in new facts to prove of much service. His sections, however, on practical considerations, the maintenance of the fertility of the air, and the relations of the agriculturist to the sanitarian are full of interest and rich in suggestion. The description of sanitation in Holland is particularly attractive, and the account of the reclamation of Carrington Moss is of great interest. But perhaps the most attractive pages of all are those in which Dr. Poore lets us into the secrets of his own delightful experimental garden at Andover.

The addresses delivered before the Royal Medico-Chirurgical Society are all worthy of being preserved within the covers of this book. They deal with such matters as typhoid fever caused by pollution of public water supplies, the protection of water supplies, application of excreta to well-tilled humus, and the relation of enteric fever to overcrowding. The study of the causation of typhoid by pollution of public water supplies, with its record of forty-six instances occurring between 1867 and 1897, should be of much service to the sanitarian. Dr. Poore maintains that under no circumstances whatever should enteric excreta be mixed with water. He holds that the great cause of the increase and wide epidemicity of enteric fever in modern times has been the water-closet.

Among the general essays here reprinted from various periodicals are those dealing with the sanitation of camps, milk and its relation to health and disease, and dietetic problems.

Dr. Vivian Poore has been well advised in publishing this reprint of his most interesting lectures and essays, and we commend the volume to all medical men and especially to those in any way concerned in the protection of the public health.

HORROCKS ON THE BACTERIOLOGICAL EXAMINATION OF WATER. (*a*)

The name of this work is somewhat misleading, as it would naturally convey the impression that the treatment of the subject was elementary, while on the contrary the contents constitute rather a complete summary of what is known on the matter than what is usually understood by the term "Introduction."

The methods of examination advocated throughout the book are on the whole sound, though perhaps in some instances they might have been described with a little more clearness and detail, even if in doing so, more space had been taken up. Considerable attention is devoted to the description of the various processes employed for the discovery and identification of the B. typhosus in water and sewerage. That of Hankin especially, is well sketched, a matter of some importance, as this process often succeeds where other means have failed in isolating that very shy bacillus. The chapter on the action and utility of filters is an extremely important one. The author, while endorsing the verdict of former experimenters as to the efficiency of the Pasteur-Chamberland filter as a perfect protection against water-borne disease, is not able to speak so confidently of the Berkeley. He shows by a series of carefully thought out experiments of his own, that, given suitable conditions, the B. typhosus will *grow through* the Berkeley bougies, and eventually infect the filtrate. This fact is of vital importance and shows the absolute necessity of a frequent sterilisation of these filters if they are to remain efficient. This should be done by boiling at least every third day.

The book is nicely got up, and the plates are distinctly useful.

LANGLEY'S PRACTICAL HISTOLOGY. (*a*)

This little book is one which ought to prove invaluable to the student. The subject, necessarily somewhat intricate to the beginner, is treated in so interesting a manner that he acquires a considerable practical knowledge almost before he is aware of it. The first chapter, dealing with the use of the microscope, is especially useful, as it gives just the information necessary and not always obtainable from the text-books placed in the student's hands. While the author throughout the work chooses the simplest methods and employs the simplest language in describing them, a vast amount of very useful practical information is given. In the appendix is a concise description of various processes of staining and hardening the tissues under examination. We can recommend the book.

Literary Notes and Gossip.

Every progressive country is beginning to realise that while in all its faculties post-graduate study is desirable, in technical matters it is essential. The science and art of medicine is necessarily progressive and calls for life-long study. And yet the opportunities for post-graduate study are still meagre and, especially in this country, lack organisation. The New York *Medical Record* for June 21st contains valuable articles on the facilities offered for post-graduate instruction in Great Britain, Germany, and Austria, and the United States. Those who propose to visit Berlin or Vienna will find much that will interest them in these articles.

⁂

Messrs. Bailliere, Tindall and Cox will publish in October, in one volume, a number of articles and addresses on surgical subjects by the late Sir William Stokes, F.R.C.S.I., whose death while serving as a consultant surgeon in South Africa is still deeply regretted. Sir William Stokes at the time he started for South Africa was engaged in re-writing these articles, with the object of publishing them, and Lady Stokes naturally desires that the publication should be continued. Professor Ogston, of Aberdeen, will contribute an introductory sketch of Sir William's life, while the task of editing the work is in the hands of Mr. William Taylor, F.R.C.S.I., Surgeon to the Meath Hospital. We are sure that the recollection of Sir William Stokes' powers as an operating surgeon and as a writer will cause many of his professional *confrères* to look forward with much interest to the publication of the volume which is in the Press.

⁂

We notice with pleasure the tendency to recognise the merits of members of the medical profession by the general public. It is not so very long since that the masters of medicine and their labours attracted little, if any, public recognition. All this is changed, and it is interesting in this connection to note the difference in the ninth and tenth editions of the "Encyclopædia Britannica." Among medical celebrities, in the first volume, we find a good biograpical sketch of Thomas Andrews, the Belfast man, who did so much for chemical science by his investigations on the heat developed by chemical actions; on the allotropic power of oxygen, ozone, and by his very complete inquiry into the laws expressing the revelations of pressure, temperature, and volume in carbonic acid gas, showing that the gas passes from the gaseous to the liquid state without any breach of continuity.

(*a*) "An Introduction to the Bacteriological Examination of Water." By W. H. Horrocks, M.B., B.Sc. Lond., Assistant Professor of Military Hygiene in the Army Medical School, Netley; Major, Royal Army Medical Corps. London: J. and A. Churchill. 1901.

(*a*) "Practical Histology." By J. N. Langley, M.A., Sc.D., F.R.S., Fellow and Lecturer of Trinity College, Lecturer on Histology and Deputy Professor of Physiology in the University of Cambridge. London: Macmillan and Co. 1901.

THE names of Oliver Wendell Holmes, S. Weir Mitchell, and A. Conan Doyle closely gather in one's memory as great novelists who were yet great in the field of action, and loyal workers in the world of medicine. The current number of *International Clinics* as its frontispiece gives an excellent photograph of Dr. Weir Mitchell in his Clinic at the Infirmary for Nervous Diseases, Philadelphia. He is shown investigating an obscure case, and surrounded by nurses and students. In the interesting accompanying sketch of his career we learn one of the secrets of the great physician's success. Dr. Mitchell's influence on young men is his marked characteristic. To his students he is ever a sympathetic and helpful friend. He is constantly suggesting to younger men new fields of labour, and instinctively knows the lines upon which investigations may be profitably pursued. Dr. Mitchell's contributions to physiology and medicine number about 140. He has published, as all the world knows, a number of delightful novels and many charming poems. He holds the belief that a physician in active practice may do what else he pleases, provided that his medical life and works assure him of his competence. Dr. S. Weir Mitchell is an example which many would fain follow.

⁂

WE congratulate our enterprising contemporary, the *Sphere*, on its valuable illustrated articles in its issue of June 28th, dealing with the story of medicine and surgery and philanthropy since the King entered on his public career, by Mr. Arthur Keith and Sir Henry Burdett.

⁂

MANY medicals are ardent cyclists, and to those who reside in the neighbourhood of London we commend Mr. Charles G. Harper's delightful and artistically illustrated new work, "Cycle Rides Round London," published by Messrs. Chapman and Hall.

Medical News.

Consumption in Cheshire.

AT a recent meeting of representatives of the various Cheshire Town Councils, Boards of Guardians, and District Councils and the Health Committee of the County Council of Cheshire, it was decided that a sanatorium or sanatoria for the treatment of consumption should be established in the county, and that steps should be taken under the Isolation Hospitals Act with a view to an order being made to include all sanitary districts, and the consent of the Local Government Board is to be sought to include phthisis within the meaning of the Infectious Diseases Notification Act.

Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the Directors of the Society was held on Wednesday, July 9th, the President, Mr. Christopher Heath, F.R.C.S., in the chair. Two new members were elected, and the deaths of three members were reported and the resignation of a member accepted. Fresh applications for grants were read from two widows and grants of £50 per annum made. It was resolved to distribute £1,342 among the fifty-five widows, eleven orphans, and five recipients from the Copeland Fund now in receipt of grants. The expenses of the quarter were £47 19s. 6d.

Pass Lists.

The Royal University of Ireland.

THE Examiners have recommended that the following candidates be adjudged to have passed the First Examination in Medicine:—Madeleine S. Baker, James Barrett, Daniel Boylan, Harry L. Bristow, Francis J. Callaghan, George F. Campbell, Holden Carson, John Dunlop, John L. Dunlop, Patrick J. Dwyer, John R. Elwood, Eleanor E. Finegan, Edward FitzGerald, William J. Gallagher, James J. A. Gannon, James Gaston, Patrick J. Grogan, Rowland Hill, James J. Hollywood, James Horgan, Robert F. Kennedy, Charles G. Knight, Samuel W. Kyle, Thomas J. McAllen, Samuel McCormac, Jerome B. Murphy, Patrick F. Murphy, Joseph Nunan, Joseph A. O'Halloran, Humphrey J. O'Sullivan, Charles B. Pearson, Percy B. Ridge, Charles H. G. Ross, James A. Shorten, Thomas Tobin, Ernest F. Watson, Henry N. Wrixon.

The under-mentioned candidates have qualified on their answering to present themselves for the further examination for honours in the subjects set after their names. Those qualified in two or more subjects may present themselves for the honour examination in all subjects:—Madeleine S. Baker, zoology; Harry L. Bristow, physics; Francis X. J. Callaghan, zoology and chemistry; John L. Dunlop, physics; Patrick J. Dwyer, zoology; John R. Elwood, zoology; Rowland Hill, botany, zoology, chemistry, physics; James J. Hollywood, zoology; Robert F. Kennedy, botany and physics; Charles G. Knight, botany, zoology, chemistry, physics; Samuel McCormac, chemistry; Charles B. Pearson, botany and zoology; Percy B. Ridge, zoology; James A. Shorten, zoology and physics; Thomas Tobin, zoology; Ernest F. Watson, botany and zoology; Henry N. Wrixon, physics.

University of Glasgow.

THE following candidates have passed the fourth (final) professional examination:—

(A).—For M.B., C.M.—Thomas Small Goodwin.

(B).—For M.B., Ch.B.—William Kirkpatrick Anderson, William Armitage, Robert James Arthur, Alexander Grey Banks, James Campbell Bringan, Margaret Elizabeth Bryson, Angus Campbell, Robert Harold Campbell, John Shedden Dale, Alexander Dick, Donald Douglas, M.A.; Andrew Robertson Dow, James Drummond, George Ferguson, John Ferguson, M.A.; Eric Dalrymple Gairdner, William White George, John Miller Gordon, John Guthrie, John Andrew Hagerty, Ronald Dingwall Hodge, John Brown Dalzell Hunter, Neil M'Coll Hutchison, Ernest David Jackson, George Rutherford Jeffrey, William Fletcher Kay, John Kennedy, Andrew Miller Kerr, Robert Laurie, Archibald Leitch, Stanley Everard Lewis, Joseph Paterson Lusk, Alexander Macintyre, Ivy M'Kenzie, M.A., B.Sc.; John Chancellor M'Kenzie, Alexander Maclean, Alexander M'Gaw M'Millan, Dugald Henry Macphail, Richard Makins, Robert Harry Manson, Janet Thomson Miller, William Alexander Milne, Alexander John Mitchell, Allan Dixon Mitchell, John Morison, John Muir, B.Sc.; James Stuart Nicolson, James Nimmo Prentice, John Mark Reid, John Walker Renton, Thomas Richmond, David Riddell, William George Rodger, Norman Cumming Rogers, Andrew Taylor Ross, James Crawford Ross, James Russell, James Smith, John Williamson Smith, Robert Cassels Smith, David Spence, John Stevenson, John Barbour Stewart, Joseph Swinburn Townley, William Wagner Turner, Thomas Irby Wallace, Alexander Brown Watt, Joseph White, M.A., B.Sc.; David Ashley Wilson.

The following candidates passed with distinction in the subjects indicated:—

In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine, (c) Midwifery—Andrew Miller Kerr, William George Rodger. In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine—Alexander Grey Banks, Ivy M'Kenzie, M.A., B.Sc.; David Riddell, James Crawford Ross, Joseph White, M.A., B.Sc. In (a) Surgery and Clinical Surgery, (b) Midwifery—Thomas Richmond. In Surgery and Clinical Surgery—James Campbell Bringan, George Rutherford Jeffrey, William Fletcher Kay, Robert Laurie, John Morison, John Muir, B.Sc.; James Stuart Nicolson, John Mark Reid. In Practice of Medicine and Clinical Medicine—George Ferguson, Eric Dalrymple Gairdner, Ronald Dingwall Hodge, Ernest David Jackson, Richard Makins, Janet Thomson Miller, John Walker Renton, James Russell, William Wagner Turner, Thomas Irby Wallace. In Midwifery—Angus, Campbell, Alexander M'Gaw McMillan, Robert Menzies.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. R., F.C.L.—Exactly what was desired.

Mr. Henderson.—The new discovery has not yet arrived in this country from America, but we hear it is likely to blossom in the autumn, and that the occupation of the medical profession will henceforth be confined to midwifery cases and broken limbs!

Mr. D. Kennedy.—Your case of suprapubic lithotomy with skiagraph to hand. Will appear in an early number.

An Edinburgh Student.—We have heard it rumoured that a new edition of the work is likely to appear shortly, but have seen no announcement to this effect. If the publishers decline to commit themselves, it is probably a case of uncertainty, and we would advise you to go on with the present edition.

R. F. H.—As far as is known, there are about 8,000 women doctors in the world, but no less than 6,000 of them reside in the United States.

X-Ray.—The diagnosis of actinomycosis can be made in three ways: (1) By the microscopical examination of an unstained preparation of the purulent material and the demonstration of characteristic bulbous rods therein; (2) By the microscopical examination of a preparation stained by Gram's method, in which there may be seen long rods or threads devoid of bulbous extremities. The spore-forms are usually encountered free in such a preparation; (3) By the microscopical examination of sections stained by Gram's method, in which both bulbous and non-bulbous rods or threads are found. It should be remembered, however, that while the demonstration of the bulbous forms establishes a diagnosis, their absence does not negative a diagnosis.

R. M.—You evidently share the popular idea of the exchangeability of the term "patent" and "proprietary" medicines. The stamp on the bottle does not establish a "patent medicine status"; it is merely an indication that the tax has been paid. As a matter of fact, there are very few "patent" medicines, and the unauthorised use of the word is punishable by a fine of £5.

Dr. Magenis.—We hope to have space for your case of "Iridectomy for Occlusio Pupillæ" in our next.

Meetings of the Societies, &c.

LONDON.

Wednesday, July 16th.

The Society for the Study of Diseases in Children.—At the Hotel Cecil, Strand, W.C. At 6.30 p.m., Annual General Meeting. At 7.30 p.m., Annual Dinner, Dr. H. Ashby (Manchester) in the chair.

Medical Graduates' College and Polyclinic.—4 p.m. Dr. Squire's Medical Clinic.

Thursday, July 17th.

Medical Graduates' College and Polyclinic.—4 p.m. Mr. Cantlie's Surgical Clinic.

Friday, July 18th.

Medical Graduates' College and Polyclinic.—4 p.m. Dr. St. Clair Thomson's Throat Clinic.

Appointments.

Barlet, Jehan M., M.R.C.S.Eng., L.R.C.P.Lond., Resident Medical Officer to the French Hospital, London.

Brown, William, M.D., C.M.Glasg., Medical Officer to the Children's Home of the Bristol Board of Guardians at Staple Hill.

McCarroll, J., M.B., B.Ch., R.U.I., Casualty Medical Officer of the Middlesex Hospital.

Peatling, A. V., B.A., M.B., B.C.Cantab., Honorary Medical Officer to the Carshalton Cottage Hospital.

Rigby, F. W., M.B., C.M.Edin., Certifying Surgeon under the Factory Act for the Bacup District of Lancashire.

Rowntree, C. W., M.R.C.S., L.R.C.P.Lond., Casualty Surgical Officer to the Middlesex Hospital.

Wright, John Aldran, M.A., M.D.Cantab., Assistant Physician to Addenbrooke's Hospital.

Vacancies.

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Clerk's Offices, 45, Hamilton Square, Birkenhead.

Brighton, Hove, and Preston Dispensary.—Two House Surgeons, one for the Northern and one for the Western Branch. Salary £160 per annum, with coals, gas, apartments, washing, and attendance. Applications to the Assistant Secretary, 113, Queen's Road, Brighton.

Camberwell.—Assistant Medical Superintendent for the Infirmary at Havil Street, Camberwell, and Workhouse at Gordon Road, Peckham, &c. Salary £150 per annum, with apartments, board, and washing. Also a Third Assistant Medical Officer of either sex. Salary £50, with apartments, board, and washing. Applications to the Medical Superintendent at the Infirmary, Havil Street, Camberwell.

City of Liverpool Infectious Diseases Hospitals.—Assistant Resident Medical Officers. Two Assistant Resident Medical Officers. Salary of £120 per annum each, together with board, washing, and lodging at the hospitals. Applications to the Chairman Port Sanitary and Hospitals Committee, Town Clerk, Municipal Offices, Liverpool, must be delivered at the Town Clerk's Office.

East London Hospital for Children and Dispensary for Women, Glamis Road, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Luncheon is provided at the hospital. Applications to Thomas Hayes, Secretary.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance. Applications to Dr. W. D. Moore, Medical Superintendent.

Newport and Monmouthshire Hospital. House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary.

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel are found for the above surgeons. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings. Applications immediately to the Chairman of the Selection Committee at the hospital.

The Bristol Royal Hospital for Sick Children and Women.—House Surgeon. Salary £120 per annum, with rooms and attendance. Applications to the Secretary.

Births.

D'Erf-Wheeler.—On June 23rd, at Jerusalem, the wife of Percy D'Erf-Wheeler, M.D., F.R.C.S., F.R.G.S., of a daughter.

Roberts.—On July 8th, 1902, at Kingsdown, Church Road, Forest Hill, S.E., the wife of Francis Henry Roberts, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Deaths.

Curnow.—On July 5th, at Wimpole Street, Cavendish Square, London, after a short illness (acute pneumonia), John Curnow, M.D.Lond., F.R.C.P.Lond., of King's College Hospital, aged 56 years.

Edwards.—On July 9th, at Everton House, Eastbourne, John Augustus Edwards, M.R.C.S., L.S.A., for many years of Crediton, Devon, aged 90.

Loch.—On July 9th, at Umballa, India, of enteric fever, Ernest A. Loch, I.M.S., second son of Deputy Surgeon General J. H. Loch, M.D., of Clifton, aged 26.

Stiven.—On July 12th, at Manor Lodge, Harrow, Edward William Flemyng Stiven, M.D., in his 51st year, after a few days' illness.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m. Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. Northern Central, 2.30 p.m.—West London, 2.30 p.m.—London Throat, 9.30 a.m.—Royal Free, 2 p.m.

TUESDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—Guy's, 1.30 p.m.—Middlesex 1.30 p.m.—Westminster, 2 p.m.—West London, 2.30 p.m.—University College, 2 p.m.—St. George's, 1 p.m.—St. Mary's, 1 p.m.—St. Mark's, 2.30 p.m.—Cancer, 2 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—Royal Ear, 3 p.m.—Samaritan 9.30 a.m. and 2.30 p.m.—Throat (Golden Square), 9.30 a.m.—Soho Square, 2 p.m.

WEDNESDAYS.—St. Bartholomew's, 1.30 p.m.—University College, 2 p.m.—Royal Free, 2 p.m.—Middlesex, 1.30 p.m.—Charing Cross, 3 p.m.—St. Thomas's, 2 p.m.—London, 2 p.m.—King's College, 2 p.m.—St. George's, (Ophthalmic) 1 p.m.—St. Mary's, 2 p.m.—National Orthopædic, 10 a.m.—St. Peter's, 2 p.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Gt. Ormond St., 9.30 a.m.—Gt. Northern Central, 2.30 p.m.—Westminster, 2 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—Cancer, 2 p.m.—Throat (Golden Square) 9.30 p.m.

THURSDAYS.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—University College, 2 p.m.—Charing Cross, 3 p.m.—St. George's, 1 p.m.—London, 2 p.m.—King's College, 2 p.m.—Middlesex, 1.30 p.m.—St. Mary's, 2.30 p.m. Soho Square, 2 p.m.—North-West London, 2 p.m.—Chelsea, 2 p.m.—Gt. Northern Central (Gynæcological), 2.30 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—St. Mark's, 2 p.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Throat (Golden Square) 9.30 a.m.

FRIDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—Guy's, 1.30 p.m.—Middlesex, 1.30 p.m.—Charing Cross, 3 p.m.—St. George's, 1 p.m.—King's College, 2 p.m.—St. Mary's, 2 p.m.—Ophthalmic, 10 a.m.—Cancer, 2 p.m.—Chelsea, 2 p.m.—Gt. Northern Central, 2.30 p.m.—West London, 2.30 p.m.—London Throat, 9.30 a.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Throat (Golden Square), 9.30 a.m.—City Orthopædic, 2.30 p.m.—Soho Square, 2 p.m.

SATURDAYS.—Royal Free, 9 a.m. London, 2 p.m.—Middlesex, 1.30 p.m.—St. Thomas's, 2 p.m.—University College, 9.15 a.m.—Charing Cross, 2 p.m.—St. George's, 1 p.m.—St. Mary's 10 p.m.—Throat (Golden Square), 9.30 a.m.

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 p.m.) and the Central London Ophthalmic Hospitals operations are performed daily.

Paris Clinical Lectures.

THE DELIMITATION OF THE HEART BY PERCUSSION AND SKIAGRAPHY, BEING A COMPARISON OF THE TWO METHODS.

By DR. POTAIN,
Professor at the Faculty of Medicine of Paris.

[FROM OUR PARIS CORRESPONDENT.]

A TOLERABLY accurate appreciation of the size of the heart and the changes which it undergoes are of unquestionable diagnostic importance. Although we are, in this respect, far ahead of the time of Corvisart, when hypertrophy of the heart and dilatation under the name of passive aneurysm, constituted practically the then knowledge of cardiac pathology, the overgrowth of that organ remains, in a large number of cases, the essential feature of the cardiac affections; and, in many cases in which the orifices are primarily attacked, the degree of dilatation which the cavities undergo is one of the principal indications of the gravity of the lesion. Lastly, when either the parietal endocardium or the myocardium alone is involved, the increase in size furnishes the most trustworthy guide to the existence of the lesion. Even in the physiological state, the size of the heart is far from constant. These variations in size are at times due to very trivial causes, which do not excite suspicion unless attention is drawn to them. Always an interesting study, they are also at times the indication of impending mischief, which must not be overlooked.

We have various means at our disposal for the recognition of these variations in size. But these means are far from being of equal value. Those which are usually employed are: (1) bulging of the præcordial region; (2) the force of the cardiac beat; (3) the exaggerated area of the apex beat; (4) displacement below and outside the spot where the shock of the apex is felt; (5) the delimitation of the organ by percussion. To these must now be added radioscopy and radiography. But we must not allow ourselves to be dazzled by this superfluity of means —it remains for us to ascertain the precise value of each of them, and the conditions under which they may be employed.

The first three afford very vague indications, which are met with in cases of very marked hypertrophy, but are wanting in less marked cases; they are, moreover, a frequent source of error, and, speaking generally, they only enable us to arrive at an approximate estimate of the increase in size. The displacement of the apex is a more trustworthy sign, but still does not enable us to measure the degree of hypertrophy or dilatation. We know, as a matter of fact, that in many subjects the apex beats normally in the fifth intercostal space, while in others it is in the fourth. If therefore we find it in the fourth we may rest assured that there is no hypertrophy; if it is in the fifth we learn nothing, since it may have been displaced in the event of its having originally been higher up. In the sixth it certainly shows an increase of size, but as it hardly ever goes to the seventh the displacement in the sixth is the only sign of hypertrophy either great or small. Its displacement to the left has a greater range, but it is not worth much except in respect of changes in the shape of the right cavity.

We now come to percussion of the præcordial region, which certainly gives more exact indications. It has, however, its critics, especially Prof. Tripier, of Lyons, who, in his work on cardiac semiology, maintains "that it only yields more or less vague results, except in cases of pericardial effusion or marked hypertrophy, because, if the borders of the lungs impinge on the vessels (?) this method fails to give any result." It is certain that, to obtain exact and comparable results, the delimitation of what is called the area of præcordial dulness must be performed systematically by precisely similar methods. I have already mentioned the one which I consider the best and which I always employ. I will refer to it here because it has been variously criticised.

In order to thoroughly understand it, we must bear in mind that in contact with the anterior thoracic wall, the heart resting on the liver behind the anterior edges of the two lungs, represents a large triangle with the base below, with a very obtuse and rounded upper angle, the left side of the triangle ascending very obliquely from the apex of the heart towards the apex of the triangle to the right side, merging with the right border of the sternum or overlapping it more or less. When we wish to delimit this area by the aid of percussion, I hold, contrary to the general opinion, that we must abstain from tapping on the præcordial region, but content ourselves with tapping along the periphery, along a series of convergent lines which start some distance from the usual limit of the præcordial dulness and run perpendicularly to the lines which circumscribe them. As long as the percussion is over a portion of the lung outside the heart the sound is full, grave, and apparently equal throughout, if there be no pulmonary lesion. The limits of the lung having been reached, the percussion note suddenly rises owing to the fact that the thickness of the layer of lung thrown into vibration suddenly becomes less. This rise in tone warns us that we have reached the limit. That point should be marked with a pencil. To continue percussion towards the centre of the præcordial region would mean waste of time.

We must bear in mind that it is not by a sudden and marked fall of the volume of sound, *e.g.*, by obvious dulness, that we recognise the instant we have reached the heart, but by a change in the *timbre* of the sound. This change is readily perceived when we are on the look-out for it. If, on the contrary, we are expecting merely diminished resonance, the heightened tone easily gives the illusion of increased volume.

We start therefore by determining, if possible, by the aid of palpation, the exact site of the apex beat, by percussion, the exact circumference encircling this spot, for this is a most essential part of the perimeter, and the most difficult to define exactly. Then we determine the corresponding line on the left and right of the dulness; lastly, the very rounded upper angle which corresponds to the arch of the aorta, since it is understood that the dulness that can be made out necessarily includes this spot.

It now remains to determine the lower limit of the heart, that which corresponds to the right border of this organ, and separates it from the liver on the upper surface whereof it lies. This, however, presents special difficulty, because both the organs in contact are equally dull on percussion, and it is extremely difficult to seize the exact shade of difference which distinguishes the two dulnesses, although the possibility of doing so has been asserted. I have adopted the method introduced by Constantin Paul, which consists in first of all determining, by percussion, the upper limit of the liver just as for the limits of the heart; then, starting from the point at which the line indicating this limit meets that of the right edge of the præcordial dulness, I draw another to join the lower border of the apex. It is true that this latter limit is artificial and passes across a portion of the right ventricle, which impinges on the upper surface of the liver.

When M. Bianchi, of Naples, proposed the method of delimitation to which he gave the name of phonendoscopy, I endeavoured to apply this method in the determination of the line which separates the liver from the border of the heart. I saw that it was practicable, especially by combining it with friction of the skin, not by following the converging lines leading to the foot of the instrument as M. Bianchi did, but by following circumferences having this spot for centre, and cutting the line of separation of these two organs. I also noted that the same result could be obtained with an ordinary stethoscope. Lastly, going back to the methods of Piorry, I discovered that there really was a rather marked difference between the sound given by the heart, and that given by the liver under digital percussion, and that it was possible to trace sufficiently accurately the limit between the two. I am inclined to think that this difference is due to pulmonary resonance produced by percussion of the heart, the gastric and intestinal resonance being influenced by that of the liver. But this is of little importance so long as the distinction is possible. What causes me to rely upon these rather laboriously obtained results is, that the limit obtained was always approximately identical, whichever of the three methods I employed.

This having been achieved, I endeavoured to ascertain the relative value of the portion of the præcordial dulness obtained by the method of Constantin Paul. To do this, having collected a fair number of drawings giving both the liver-apex line of C. Paul and the true limit of the border of the heart, I measured the inscribed surfaces by the aid of Amsler's planimeter. The result was that the portion left outside the tracing by the method of C. Paul was nearly always one twenty-eighth of the total area of dulness.

I do not therefore feel called upon to abandon the method which I first of all adopted, since it goes without saying that we cannot obtain, by the aid of percussion charts, either a true outline of the heart, since we only obtain a surface projection of a heart placed obliquely; nor its exact dimensions, since we include the aorta, which does not belong to it, but only a figure which sufficiently represents the real size of the organ. But, as the portion excluded by our method is constantly proportional to the whole, it results that, with or without it, we can always estimate in the same manner the proportion between the dimensions obtained and the normal dimensions. We may, therefore, assert that both methods are equally good in regard to the results which they furnish. But as the delimitation of the border of the right ventricle is above all extremely delicate, as it demands great attention and care, and may certainly give rise to more errors than the other, I think it better to keep to my method, especially as comparison with the numerous previously acquired data would only be possible by introducing a correction; otherwise we should have to begin over again.

One consequence of the recently-introduced method is that we must always mention, when stating a given result, by which method it was obtained.

Once in possession of an exact drawing of the præcordial dulness, in order to judge how much this dulness differs from the normal we have only to measure it. For a long time we have contented ourselves with measuring the length and height. But this double dimension makes comparisons rather difficult. These are much easier if we measure the area of the surface, and this may be done in several ways. The simplest, and the one, for example, which M. Cassaet advises, consists in transferring this drawing to a paper ruled in squares and then to count the number of squares contained. But if the squares are large, this does not give very exact results; while if they are small, the calculation is very tedious. Another way consists in cutting out the drawing which has been traced and weighing it against a piece of similar paper of known dimensions. This may be very exact, but it too is rather tedious. Lastly, there is one method which gives in an instant a measure of absolute precision, and that is Amsler's planimeter. The addition of another instrument to those which we are already compelled to use, although it may be worth the trouble in a particular series of observations in order to make them as exact as possible, is really unnecessary in every-day practice.

After having measured in this way a very large number of drawings, I found that it was possible to obtain a fairly correct estimate by measuring the length and height of the drawing, and then multiplying each one by the empirical cœfficient of 0·83. One precaution is however necessary when the line corresponding to the right edge of the dulness, instead of descending almost perpendicularly to the base of the triangle, is oblique and falls outside, viz., to lower a tangent perpendicular to the extended base, and to add to the length half the distance which separates the foot of this tangent from the right lower angle of the dulness.

Measurements made on a large number of adult men furnished me with a minimum of 90 cc. I cannot make any positive statement concerning the heart of women in the normal condition, since I was unable to obtain a sufficient number of drawings of women in an absolutely physiological state.

The principal objections which have been made to the use of percussion in estimating the size of the heart are that it is difficult of execution, and only gives uncertain and often conflicting results, according to the methods employed and the persons who employ them. This criticism would be justified, as

I have said, if we did not make use of a constant method and pay sufficient attention. It is not justified when these conditions are fulfilled. As to the difficulty, it is far from insurmountable. I have had this percussion performed very often in my presence by my students, and then without seeing the result, have myself repeated the process, and obtained absolutely identical limits.

But the question which semiologists must especially have in view is that of ascertaining in what measure the limits of this dulness exactly correspond with those of the organ delimited. For, in spite of the precision with which we may circumscribe this dulness, in spite of the identity of the limits found by several successive observers, it is possible, after all, that they only correspond very imperfectly with the real outline of the heart, and that the propagation of the vibrations imparted to the thorax by percussion in various directions differs from them more or less.

Percussion practised on a corpse, unfortunately, gives uncertain results which cannot well be compared with those obtained on a living person, owing to the excessive tympanism of the dead thorax. The comparison of the dead heart with the drawing obtained during life is also rather unsatisfactory, and must necessarily be somewhat vague and uncertain, since the size of the heart may have changed in the interval between the delimitation and the autopsy; moreover, in the dead the heart is not always the same size as during life, either because it undergoes a more or less marked dilatation during the agony, or, on the contrary, because its contents have been more or less completely drained away.

In the endeavour to test the accuracy of the delimitations practised in my wards, I found that the only way was to take, on the one hand, all the post-mortem examinations during a long series of years in which the volume of the heart had been carefully noted, and then to take all the measurements of the area of the dulness in the corresponding patients and to schedule the cases in three classes according to the size indicated. Now, we found that the three classes corresponded exactly, and that there was never in this respect any noteworthy error. But even this left us far from that degree of precision which is desirable in this verification. No greater precision, however, was possible for reasons which I have already given, also because the diameters of the heart measured at the post-mortem examinations do not correspond to those of the contact projection of the heart on the thoracic wall. Radioscopy has fortunately furnished us with an infinitely more exact means of control, and the two tests can be applied almost simultaneously, thus furnishing us with data for careful comparison.

The results given by radioscopy are not, however, exempt from error nor are they able to dispense with corrections. Like percussion, they include the aorta in the perimeter indicated, like it they confuse the lower border of the projection with that of the liver. Moreover, owing to the divergency of the Röntgen rays, a divergence which is rather marked owing to the impossibility of placing the source of the rays far away from the object, there is produced on the screen an enlargement of the image which it is indispensable to bear in mind. Lastly, the limits of this image, always rather blurred, present a zone of twilight in which it is not very easy to distinguish exact limits. However, by selecting cases in which the image is sufficiently clear, or by making it such by the use of a suitable diaphragm, by noting very exactly the distance of the source of the rays, its position, the shadow of the thorax, and the situation of the screen, we are able, either by calculation or in the way indicated by M. Variot, or by an extremely simple graphic construction, to make the necessary corrections, and to obtain an image which may be considered as representing a projection of the heart and aorta on the thoracic wall in its true dimensions. This is the one which may be usefully compared with the charts furnished by percussion.

To facilitate this comparison, after having traced on the thorax the limits of the cardiac and aortic dulness, I make a tracing of the radioscopic image by the aid of tracing paper, for my guidance, the upper border of the liver, the lateral edges of the sternum, the sternal notch and the borders of both clavicles. Then I transferred the whole to glass by the aid of ink, and apply this to the radioscopic screen; and lastly, I place the latter in front of the thorax, taking care to make my guiding points coincide with those which ought to correspond thereto in view of the position of the source of the rays.

Under these conditions I always found the percussion tracing correspond very closely with the radioscopic image. Having traced the latter on glass and made the necessary corrections by the aid of the construction I mentioned, it was found that the two images, that of percussion and the corrected radioscopic image, almost always exactly coincided.

On one occasion only did I discover a slight discrepancy. The radioscopic image, even when corrected, showed the right auricle a little outside of the limit indicated by percussion. Starting the latter afresh I found that the semi-dulness produced by the auricle behind an emphysematous lung really commenced a little earlier than had been marked. I inferred that the depth at which the most prominent part of this auricle is situated renders its delimitation extremely difficult, and necessitates very careful percussion.

More than once I have had occasion to use percussion and radiography in the determination of rapid modifications in the size of the heart, and the results always coincided.

We may, therefore, affirm that both methods furnish very reliable results, and this clearly confirms the value of percussion. These results having been obtained by absolutely dissimilar means, it is impossible to conceive that any errors could coincide.

Although radioscopy can thus assist in verifying the results of percussion, we must not therefore conclude that it is to be preferred as a means of diagnosis, and substituted in practice.

We have shown that the results, however obtained, are practically identical, we might, consequently, as well say that percussion enables us to control the results of radioscopy. It is not as if radioscopy were easier or simpler to employ than percussion; on the contrary, it requires vastly more care and attention and at least as much previous experience. It necessitates more corrections than does the drawing by the plessimeter. It leaves us just as much exposed to form erroneous deductions, and leads, in careless or insufficiently practised hands, to gross errors, of which I have met more than one example. Moreover, these errors are the more vexatious owing to the blind faith which we place in an apparatus which we imagine to be infallible and which must, we think, furnish indisputable results.

Lastly, it is not always possible for it to be utilised, for the apparatus is very cumbersome, and, therefore, difficult to convey from place to place. The patient must be taken to the apparatus, and, in consequence of this, it cannot be utilised in the case of patients unable to be moved.

Percussion, on the contrary, can always be practised without the aid of any instrument or apparatus, and since it gives identical and equally exact results is, in a general sense, infinitely preferable.

Moreover, it would be highly regrettable should the rising generation of practitioners abandon the practice of percussion and pin their faith exclusively to radioscopy in regard to the delimitation of the heart.

Not that radioscopy or radiography, in careful and experienced hands such as those of the adepts who practise in our hospitals, cannot furnish data very useful to the study of heart disease, data which confirm or invalidate those obtained by other methods. What I mean is that neither method can or should take the place of the other.

TUBES AND CYSTIC OVARIES
FROM A
RUDIMENTARY UTERUS:
SECONDARY GROWTH FROM THE ABDOMINAL CICATRIX AFTER HYSTERECTOMY. (a)

By R. D. PUREFOY, M.D., &c.,
Master of the Rotunda Hospital.

The first specimen was removed from a single woman. æt. 23, one of a family of eight children, all healthy; she had had no severe illness in childhood, or since. At sixteen she began to suffer at intervals of two, or three, months from severe pain in her left side and back, accompanied by headache and vomiting on first day. The pain in the left side sometimes extended down the left leg as far as the foot, and rigors commonly occurred once during such attack. These attacks rendered her incapable of any useful exertion and she therefore came under my care about three weeks ago. She was a tall, well made, and well nourished young woman, and had never menstruated, though the breasts and external genitals were normal in size and appearance. On separating the labia, the hymen was observed to be imperforate, and further examination showed that there was no vagina; the uterus was represented by a small solid body about 1 in. in length and a quarter of an inch in diameter; and on each side a large cystic ovary could be easily felt. The removal of these appeared to be the most rational treatment, and this I did a week ago, the patient being now quite convalescent. On the left side the tube bore the usual relation to the ovary at its fimbriated extremity; at its uterine end it became gradually smaller and more attenuated till it was lost in the fold of peritoneum which extended across the pelvis to the right side, where the abortive uterus was found, and, springing from its cornu, the right tube, much smaller than usual, and closely related to the corresponding ovary, which, like the left, was considerably enlarged and thickly studded with small cysts. I believe such a coincidence of normal and abnormal conditions in the utero-ovarian system is uncommon. Interesting questions are suggested by the clinical fact that, though the ovaries are so similar, pain was referred only to the left, and by the rigors and rise of temperature (1½°) which attended the menstrual molimen.

The second specimen is from a woman, æt. 40, mother of four children; for some years suffering from the increasing size of her abdomen, due to a large firm tumour springing chiefly from anterior surface of uterus, and attended with menorrhagia, and marked impairment of general health. I performed panhysterectomy, and had unusual trouble in controlling the bleeding owing to the number and size of veins and the abnormal distribution of the uterine vessels. An excellent convalescence ensued, and when I removed the abdominal stitches eight days later, the cicatrix was all that could be desired. On raising the dressing a few days afterwards I found it was adherent to a mushroom-shaped growth springing from the upper angle of the wound, which passed close by the navel. Its widest part was about 1·25 ins. in width, and the pédicle about half-an-inch in thickness. An elastic ligature was passed round it, and some days later a silk one was applied; neither caused any pain, and after a little time the mass was easily removed with scissors. Though insensitive it was amply supplied with blood, and I was consequently content to proceed very slowly with its removal.

I have had one similar experience, though the cases present points of contrast worth noting. About two years ago I removed a moderate-sized ovarian cyst from a delicate middle-aged woman; and (as in the case just narrated) an excellent cicatrix was present on the eighth day, when I removed the abdominal stitches. About five or six days subsequently a pedunculated growth, larger than in any other case, was found springing from a point about the middle of the wound. Its growth was unattended by pain of any kind, and in places its surface was quite smooth, though for the most part looking like granulated tissue. Its removal was effected, as in the other case, by repeated ligatures. The patient returned to the country, and at any rate some months afterwards was in good health. I am not aware that such a sequel to hysterectomy has been reported, especially where the tumour removed was benign. On page 56 of Mr. Sutton's work ("Diseases of the Ovaries") the occurrence of such growths after ovariotomy is noted and explained, though no account is furnished of the microscopic structure of the tumours.

IRIDECTOMY FOR "OCCLUSIO PUPILLÆ SINE SECLUSIONE PUPILLÆ."

By EDWARD MAGENNIS, B.A., M.D.

This interesting and rare condition, in which membranes grow across the pupils and cause partial or complete blindness, was brought under my observation some time ago in the case of a tradesman, whose vision had become so defective that he had to be led into my study by his brother. I performed an iridectomy on both eyes, with the result that he is now enabled to earn his livelihood and his sight was so improved that three months after the operation he could see sufficiently well to write me a letter.

The history of the case is briefly as follows:—J. H., æt. 44, a strong, healthy man, a tailor by trade; good family history. His vision was excellent up to about sixteen years ago, when he had inflammation of both eyes so bad that he was detained in an eye hospital for some weeks. Since that time he has had several similar attacks. After these attacks he noticed his sight beginning to fail, and he says he occasionally saw "clouds floating in front of both eyes like waves of water." His vision gradually and steadily became worse. On examination I found that the pupillary fields were almost entirely covered with an exudate, the result of the numerous attacks of iritis which, in time, had become converted into thin membranes of connective tissue, and the layers of retinal pigment on the posterior surfaces of the irides had become, here and there, adherent to the capsules of the lenses. The membranes stretching across the pupils were in like manner attached to the lenses. On ophthalmoscopic illumination, through the chinks in the membrane, I found the fundus reflex good in all directions in both eyes, the anterior chambers were but slightly shallowed. I learned from him that during his stay in hospital drops had been put into his eyes, presumably to dilate the pupils and break the adhesions, but they invariably brought on attacks of inflammation, and he suffered great pain. I performed an iridectomy on the right eye. I did it upwards, as I dreaded, from the disturbance of severing the adhesions, that a cataract would speedily form.

(a) Read at the British Gynæcological Society, July 10th, 1902.

When I caught the iris in the forceps it was so friable, from atrophy, it gave way, and only by a sort of wriggling, side to side movement of the forceps, and by the exercise of extreme caution was I enabled to get it out of the wound and to avoid an irido-dialysis.

On removing the dressings next day I found the anterior chamber refilled, and the eye looking well. Three weeks afterwards I operated in a similar manner on the left eye, and the iris here was even more friable than that of the right.

On examining the fundi, when the eyes were sufficiently well, I found extensive choroiditis in both. This I attributed to an extension of the inflammation from the iris to the choroid.

The condition "occlusio pupillæ," or shutting up the pupil, was here brought about by a fairly well-organised membrane stretching across the pupil, yet the condition "seclusio pupillæ," or shutting off of the pupil, was not perfected, inasmuch as the adhesions round the pupillary margin were not complete, but only occurred at particular spots, thus allowing tolerably free communication between the anterior and posterior chambers.

I had some doubts as to the advisability of operating in this case, as it was impossible to accurately judge the true condition of the fundi, and seeing the perfect state of organisation of the membranes I concluded that the pathological adhesions would be very firm, and that their breaking up might cause rapid degeneration of the lenses. However, my patient earnestly solicited that something should be done, and believing that an iridectomy, besides the immediate improvement of vision, would have a beneficial effect upon the nutritive condition of the eye, I decided to operate. Here was a married man with a large family dependent on him, and unless something was done his wife, his children and himself would have become parish charges. He is now making a respectable livelihood by soliciting orders for clothes, he wears dark-coloured spectacles, and is able to read ordinary print.

PHYSICAL EFFICIENCY IN CHILDREN. (a)

By Sir JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.

Amidst the multitudinous scintillations of minute physiological exploration, the brilliant discoveries of bacteriology and the curious side-lights of experimental psychology, we have somewhat lost sight of the assistance that the patient employment of the scales and tape measure is capable of affording us in understanding our human economy and in regulating human progress. The time has come however, for an awakening on the subject of physical efficiency and for the bestowal of due attention on the methods by which it may be gauged. We have begun to realise that the conditions of industrial competition in the world have changed, that we in this country no longer possess the incontestible superiority in skill and productive power we at one time enjoyed. We have begun to perceive that the competing nations around us are becoming commercially transformed and are encroaching on our markets more and more, and we have begun to discover, with consternation, that we are losing not only our geographical advantages, but to some extent, the stamina of our people. The diminished death-rate upon which we have been wont to pride ourselves is but a sorry comforter if the population we are keeping alive is increasingly sickly and debilitated, and technical education will be of small avail if the standard of health among our working classes is being gradually lowered. And unhappily there is evidence of a striking kind that the people of our large towns at any rate are physically deteriorating. The sum-total of our physical shortcomings must be a figure that it would be woeful to contemplate. But apart from statistics, anyone who has watched the stream of men, boys and girls, issuing from a factory in the East End of London or any large town, must recognise the fact that they are stunted and pale and weak-looking when compared with our agricultural population.

The decline in physical vigour of our urban population must, of course, be attributed to the conditions of town life generally, but of these there is, it seems to me, one predominantly influential, and that is insufficient feeding during infancy and childhood. It is the want of nourishment during the growth period that is the principal cause of the dwarfing and enfeeblement of our towns-people—and that want of nourishment is due to poverty—either as defined by Mr. Seebohm Rowntree in his masterly treatise, primary, when the whole earnings of the family are inadequate to its proper maintenance, or secondary, when the earnings, although enough for maintenance, are absorbed by other expenditure, useful or wasteful.

These figures of Mr. Seebohm Rowntree afford a painful but edifying glimpse of the havoc that poverty is playing in our wage-earning class in towns, and of the physical deterioration that is going on among the poorest portion of the community; and on no small scale, for he calculates that nearly 30 per cent. of the population are living in poverty and are ill-housed, ill-clothed and underfed.

Dr. Noel Paton and Dr. Dunlop, after searching investigation and careful analysis, have concluded that the diet of a typical labourer's family in Edinburgh is decidedly too small to support even moderate labour, both when estimated in calorics and in proteid value, and they suggest the possibility, that the inhabitants of large cities may have their growth and working capacity limited not only by poverty but by bad teeth and digestive inadequacy. They show that the food supply of our poorer working classes compares unfavourably as a source of energy and most unfavourably as a source of proteid with the diets of the inmates of poor-houses, prisons and lunatic asylums, and they point out that this food deficiency is experienced not merely by the drunken and thriftless, but by the steady, industrious, frugal poor, who cannot make both ends meet. Especially harmful to growing children of restless habits must this food deficiency be, particularly the curtailment of its proteid constituents, for all observers are agreed that in Europe good health and normal development cannot be long maintained without a full proteid allowance. We can scarcely be surprised to find degeneracy of offspring when we learn that large numbers of mothers of the poorer working classes are during pregnancy and nursing confined to a diet consisting almost exclusively of bread, dripping and tea.

The children of the poorest section (those of whom a considerable contingent may be seen every Monday morning seated with their little weekly bundles on the steps at the door of the pawnshop, waiting for it to open), are said to present a pathetic spectacle. They bear in their puny bodies, sore eyes, filthy heads, swollen glands and lame joints, the unmistakable marks of privation and neglect. They are sent into the world grievously handicapped. Through no fault of their own, these dirty atomies have been deprived of their germinal birthright. They have been subjected to sufferings that leave scars behind, they have had their score of vitality reduced, and so are left with a diminished power of resistance to the temptations to which they will be exposed, and with a diminished capacity for bread-winning; and they have been cheated of fair proportion, and disfigured in a way that is past remedy, for it is a lamentable fact that no subsequent supply of nourishment, however liberal, will fully compensate for starvation during infancy and childhood. Time lost in growth can never be completely made up. Thus it has been found on training ships to which pauper boys from metropolitan unions and parishes have been sent, that under the most generous treatment and living singularly healthy lives, they always remain more or less stunted in development. The boys sent to these ships are selected, and are certainly not of the worst and most depraved pauper class; but while a marked and most encouraging improvement takes place in their bodily health, bearing, and general intelligence, they retain in their low stature a record of the hard usage and poor feeding of their early days. I recollect that in the prologue to an entertainment given by the boys on board the *Exmouth* there occurred these lines:—

(a) Abstract of the Presidential Address delivered on July 16th in the Medical and Hygienic Section of the International Congress for the Welfare and Protection of Children.

> "And yet there's one thing saddens us and that is—
> That we with all our pudding, beef, and gravy,
> Can't reach the standard of the Royal Navy."

The enduring effects of an early blight are painfully illustrated in Mr. Cheattle's recent report on the Hanwell Poor-law Schools. He found that of 1,000 children in these schools 520 could not pass the whisper test for hearing, 335 were or had been the subjects of discharge from one or both ears, eighty-eight were suffering from chronic suppuration, and 434 had adenoids.

I have dwelt on the feeding of children because that is, I believe, the paramount consideration in relation to their physical efficiency.

"Whence shall we buy bread that these may eat?" is, to my thinking, in its economical and national aspects, the pressing question of the hour, for enhanced physical efficiency is indispensable if we are to hold our own in the world. The United States of America are becoming formidable in their rivalry to us, not only because of their spirit of enterprise, marked ingenuity, and boundless resources, but because, as recent investigations have proved, their workers are better nourished than ours. The food question is really of infinitely more moment in the restricted area to which it applies than the education question about which we hear so much (though, of course, they are to some extent bound up with each other), for education cannot take the place of nutriment and "the sincere milk of the word" is no substitute for that of the cow. It is for statesmen, diplomatists, and publicists to grapple with that question in its larger bearings, while local authorities, philanthropic agencies, and neighbourly good feeling deal with it in detail. Much has been done to alleviate the pangs of underfed children, but the evil is a gigantic one, and is not to be met by the supply of occasional meals.

It is for my own profession to supply information as to the best and most economical foodstuffs and as to the best balanced dietaries for the working classes. On that subject I dare not enter here beyond pointing out the danger of the faulty bread and tea meal, and the high value of porridge and milk. It has been calculated that an entire day's diet of tea, bread and butter on the one hand, and of porridge and milk on the other, gives a balance in favour of the latter of 22 grains of proteid, 32 grains of fat, and 100 calories at a cost of 4·5d. against 5·2d. for tea, bread, and butter, a saving of ·7 of a penny, or nearly three farthings a day. Unhappily, porridge and milk have lost their former firm hold on Scotland, but they seem to have commended themselves at least as an addition to breakfast to the well-to-do classes south of the Tweed, and perhaps the working classes in England may be brought to recognise their advantages as well as those of lentils, beans, peas and bacon, also highly nutritious and cheap foods.

There is one source of physical impairment in children, besides underfeeding, to which I would particularly allude, because its influence is direct and obvious, and that is child labour. The raising of the age for half-timers has been salutary, and the introduction of automatic machinery, the spread of education and the force of public opinion, are steadily circumscribing this kind of employment; but it still exists in certain districts, especially in the textile trades, and where it does exist its pernicious consequences are appreciable.

Rapid changes are taking place among us in consonance with our quickened rate of living. I might instance the sudden appearance during the last fifteen years among the wealthier classes of large numbers of women of the tall, willowy and narrow pelvis type, the antithesis of the plump, thickset, rotund Englishwomen whom Nathaniel Hawthorne forty years ago described as occupying an undue share of their Maker's footstool, thereby giving great offence. On all hands transformation good or bad is in progress, and it is surely expedient that by stocktaking and physical appraisement of our children from time to time we should ascertain the directions in which the several constituents of our population are moving. Man is now engaged in retracting intelligently the several steps through which he has automatically evolved, and it behoves him to determine as far as may be the laws regulating his own growth, and to apply the knowledge thus acquired to the betterment of his kind. Lord Grey has told us that we have nearly doubled the size of our cattle and sheep during the last century by recording their weights and paying careful attention to their requirements. Human beings are not so readily handled as flocks and herds, either as regards their breeding or feeding; their instincts, their aspirations, their volitions are complex and difficult to control; the medium in which they move is in incessant flux, and they themselves are highly migratory; their organic response to external agencies is slow, and often hard to interpret, but still I am fully persuaded that by measuring and weighing their young, and by paying careful attention to their requirements, we may in less than a century vastly improve their physical condition, and that is the foundation upon which moral and intellectual improvement must be reared. I am fully persuaded that it is by securing an adequate supply of suitable, wholesome, unadulterated food to the children of the submerged fourth of our town population that dwindling in stature and general degeneracy can be best prevented, and our national physical efficiency best maintained.

In these days, in this country at any rate, we have both too much and too little physical exercise. When it becomes the object of life, is pursued for its own sake and is associated with betting, it becomes one of the varieties of physiological intemperance, has a pernicious influence on life and character and sometimes eventuates in dilatation of the heart, aneurysm, or other morbid catastrophes. One refers to the subject with fear and trembling, but I cannot refrain from expressing my belief that there would be a gain in health and happiness to the upper classes, if they would make some of the physical energy they now lavish in amusement definitely serviceable. There was considerable force in Mr. Dooley's observation that the Battle of Waterloo was won not on the playfield at Eton, but in the potatoe patches of Wexford. The healthy, well-fed, well-made child, living a natural country life, may be safely left to regulate its own physical exercise. Its "*besoin de respirer et de folâtrer*" and its curiosity, and the solicitations of the beauty and wonder round it, will amply stimulate its active powers and the sense of fatigue will keep them duly in check. But the town child, living under highly artificial conditions, and often amidst narrow limitations, requires guidance and encouragement in its exercise, and opportunity for its indulgence. We hope to make a lot of our town children into country children one of these days, but there must always remain multitudes of town-pent little ones, and for them the means of physical exercise must be provided. First of all, we want open spaces, parks and gardens planted with trees and flowers to appeal to the æsthetic sense, and playgrounds in which the children can unrestrainedly frisk about.

Besides feeding and physical exercise, multifarious agencies operate on the child and help to make or mar its physical efficiency, and all these I would sum up under Mothering, Homing, and Schooling, which I name in the order of their importance. Mothering, in its widest sense, includes the physical care of the child, as far as family means allow, and those moral influences that, more than anything else, mould its character and bias its career. Matthew Arnold said that four-fifths of life are conduct; and it has been remarked that the only error in his statement is that it did not include the other fifth. Well, for my part, I am satisfied that in a large majority of men and women four-fifths of conduct are of the mother's making. It is hers by natural affinity best to understand the workings of the child's mind, and while it is in the most plastic moods to impart to it lasting impressions. It is hers, if she be worthy of motherhood, to implant sustaining ideals, and to teach the child to love and admire, to trust and endure, and to postpone the advent of jealousy and doubt. And as regards an enormous preponderance of the mothers in this country I rejoice to believe that their maternal duties are, according to their lights, well and faithfully performed. Exceptional instances of cruelty and neglect are occasionally reported, and the indignation they excite shows how exceptional they are, but as a rule our English mothers of the working-classes—and I believe all medical men practising among the poor will testify to this—are, with all their ignorance, stupidity, and superstition, affectionate to their children, zealous to promote their comfort and enjoyment, tenderly solicitous for them in sickness, anxious to make them honest, polite and considerate to the weak and suffering. It is to our English mothers, I suggest, that we mainly owe the admirable conduct of our soldiers in South Africa.

But while I say this of our working-class mothers, I cannot help feeling that mothering is in danger at both ends of the social scale. There is a good deal too much of what might be called cuckooism among the well-to-do! The cuckoo has been described by Brehm as "a discontented, ill-conditioned, passionate bird." It shirks the brooding sacrifice and responsibility of parentage, and in the words of Scripture applied not altogether justly to the ostrich, "is hardened against her young ones as though they were not hers." Are there not fashionable mothers who might thus be described? I know not how to frame an indictment against a set. There is, I suppose, a super-smart set among us who retain amidst the stately circumstances to which they have been born, simplicity in living and sweet secluded domesticity, but below them there is, I am told, a smart set, rich and luxurious, many of the women of which—given up to club and restaurant and rout haunting—like the cuckoo, neglect their offspring to their own great detriment; for it is in the loving performance of maternal functions that the nature of the woman finds its fullest and finest efflorescence.

Such women delegate their maternal duties as far as possible. Feeding-bottles, nurses, French maids, governesses, and lady-helps relieve them of them, and their children grow up bereft of motherings and may be damaged in health by their deprivation. Mr. Rudyard Kipling has drawn a touching picture of a little Anglo-Indian boy who was actually dying of brain disease brought on by want of mothering, and was brought back to health when allowed to bask in it once more, and every nurse in a sick children's hospital knows what an efficacious anodyne and tonic it is, even when vicariously supplied.

The education of children labouring under tuberculosis should be carried on in special seaside sanatoria where they cannot be baneful to others, and where everything is made to minister to their restoration to health.

The King, over whose recovery we are rejoicing, whose fortitude and unselfish devotion throughout his illness have filled us with admiration, and who is Patron of this Congress, said at his first Council, "I am fully determined as long as there is breath in my body to work for the good and amelioration of my people." It is for his subjects to aid him in that noble mission, and even the humblest of them may do something by throwing his mite of personal endeavour into the treasury of public philanthropy, and in no way can the good and amelioration of the people be more surely advanced than by providing for the protection and welfare of little children.

FOUR CASES OF VAGINAL AND ABDOMINAL HYSTERECTOMY. (a)

By F. A. PURCELL, M.D.,

Surgeon to the Cancer Hospital.

Case I.—*Uterus Removed by Vaginal Hysterectomy, showing a Carcinoma of Corpus Uteri in an Early Stage.*

The case is that of a widow, æt. 54, a healthy woman, who had had no children and no miscarriages; she passed the menopause some three years ago. Her menstruation had been regular, but with pain during flow and occasional leucorrhœa. About a year ago she noticed a slight discharge, occasionally purulent and fœtid. When walking about she sometimes felt a pain as if cut by a knife. The last three months she has had a discharge of blood, as if from a slight period.

Present Condition.—External genitals normal. Vaginal wall smooth, except just inside on the right, where carunculæ are rather indurated and tender. Capacity of vagina small. Uterus to the front mobile, not apparently enlarged. Cervix sessile and almost flush with vaginal roof. Cervix nulliparous. Fornices normal. On March 5th, 1902, the uterus was curetted and the scrapings were sent to be examined microscopically by Mr. H. J. Plimmer, who reported "that the specimen is from a case of carcinoma of the endometrium," and on this report the patient was advised to have the uterus removed. On April 2nd I extirpated the uterus per vaginam. The vagina was very narrow, which increased the difficulty of the operation. The patient made an uneventful recovery.

On section, some blood clot lay along the cavity of the uterus; the section showed a small fibromyoma lodged in the muscular structure of the neck of the uterus. No definite opinion as to malignancy can now be obtained from Mr. Plimmer. He says, "I have taken some pieces, but it is spoilt as a specimen by being put into strong spirit. At any rate it will be no good for a permanent preparation."

This certainly leaves the case rather undefined.

Case II. is that of a uterus which had expelled a round polypus, about the size of a very small tangerine orange, attached by a pedicle to the posterior wall of the body of the uterus. To remove the pedicle the patient was placed under an anæsthetic, and the uterus was under process of dilatation, and when No. 9 of Hagar's dilators was being introduced it suddenly slipped and perforated the fundus, so that its end could be felt through the abdominal wall. Vaginal hysterectomy was then performed, and the patient made an uneventful recovery. On the evening following after operation the patient managed to secrete an orange, which she ate, and during the temporary absence of the nurse from the ward left her bed, and threw the peel in the fireplace. She then got back to bed just as the nurse returned, some of her dressings being found at the fireplace. In spite of this she had no sickness or hæmorrhage. The patient was a healthy woman, æt. 52, who had had no illnesses, nine children, two miscarriages, her last pregnancy six years ago ending in a miscarriage at the third month. She had had several floodings since, which would come on suddenly with a lot of clots. A large flattened polypus was found in the vagina, the pedicle, long and thin coming out of the cervix uteri. The tumour was soft and fleshy, red, and ulcerated in places, the cervix dilated. This is the case I alluded to when Dr. H Macnaughton-Jones showed Professor Bossi's instrument which he had used for dilating the cervix in a case of albuminuria of a seventh month gestation.

Case III.—The specimen of multiple fibroids of the uterus was removed by abdominal cœliotomy from a married woman, æt. 47, admitted into the Cancer Hospital, March 11th, 1902. The patient had never been very strong, had suffered from dyspepsia for a long time some years ago, had had enteric fever. No children. Menstruation began at thirteen years, a three-week period, the flow fairly copious, lasting from eight to ten days, no pain. Eight years ago she was in the Cancer Hospital, suffered from constant vomiting, no blood, constipated; she had hæmorrhoids which bled occasionally.

(a) Notes read at meeting of the British Gynæcological Society, July 10th, 1902.

Two years ago she began to suffer from a dragging pain in her right side, and she then noticed a lump in the right iliac region; the mass varied in position. There had been no alteration in her periods. On the right arm and on the right leg she had two fibrous tumours, which gave her no inconvenience.

Abdomen.—There was some tenderness in right lumbar region, but the kidney could not be palpated. A thickening, as of glands, could be felt along the right Poupart's ligament. There was a feeling of resistance in hypogastrium. Percussion was tympanitic all over.

Owing to the extreme nervous temperament of patient, a satisfactory examination could not be made.

The vagina was narrow, barely admitting two fingers; the cervix scarcely to be felt; in the anterior fornix there was some resistance apparently connected with uterus.

When the abdomen had been opened, slightly to the side of the middle line, the condition was found to be a fibroid uterus. The ovaries were also fibrous.

The tumour mass was elevated with a myoma screw and delivered, the broad ligaments on each side were ligatured and divided, then the ovaries were removed. A peritoneal flap was made anteriorly and posteriorly, the uterus amputated through the cervix, and the peritoneum was sewn together with catgut. The abdomen was closed in layers with interrupted catgut sutures. The patient made an uneventful recovery.

Case IV.—The fourth specimen is a malignant uterus removed by vaginal hysterectomy. The diseased os and neck were very much enlarged and filled up the vagina. The operation was difficult, and the adhesions of the bladder were extensive. A blood clot presented in Douglas's pouch, which was scooped out and cleaned. Eventually the uterus was removed, but the ovaries were allowed to remain. All vessels were tied with silk, the ends left long. The vagina, after being gently douched and cleaned, was plugged fairly tight with iodoform gauze. For the first dressing a self-retaining rubber catheter was passed up into the bladder. The patient made an uneventful recovery, and the tear in the bladder healed up satisfactorily.

Clinical Records.

SUPPURATING OVARIAN CYSTOMA COMPLICATING MISCARRIAGE DURING THE THIRD MONTH.—OPERATION.—RECOVERY. (a)

By H. Macnaughton-Jones, M.D., &c.

The complication of a suppurating ovarian cystoma with pregnancy, though not of frequent occurrence, is occasionally met with. The suppuration is, however, more frequently attendant upon or a sequel of labour. A few years since I brought a case before the Obstetrical Society of London, in which, some time after parturition, I removed an enormous quantity of pus from a cyst, which had contracted extensive peritoneal and bowel adhesions, the patient making an admirable recovery. It is difficult to say why suppuration should occur more frequently in such cases than in uncomplicated ovarian cystoma. The condition of the blood in pregnancy may predispose to its occurrence. Pressure on the cyst and infection from the bowel may also tend to bring it about. In the present case there was no suspicion that the cause was ovarian until I saw the patient shortly before I operated. The case is interesting as having happened after a miscarriage about the fifteenth week of pregnancy.

On the evening of April 25th I was called in consultation to a patient who was dangerously ill, with the following history and symptoms. She was a primipara, æt. 35. There was a previous history of some lung trouble, and also of pelvic pain. On April 9th she had miscarried, and according to the report I was given the ovum and membranes had come away entire. There were no symptoms until April 20th, when she first complained of pain. Vomiting set in on the 23rd, and on the 24th there was great pain and difficulty in micturition. The vomiting continuing, and the temperature reaching 104°, and the pulse becoming feeble, I saw her. I found the abdomen generally swollen, tender to the touch, with a dull suprapubic area and attendant hardness. By vaginal examination I found the uterus fixed, the os uteri not patulous, and a considerable swelling in the utero-vesical space. There was no discharge. Her temperature had fallen to a little over the hundred, and her pulse was ninety. Ice was applied to the hypogastrium, and the quinine and opium she had been taking were continued. On the 26th she was in much the same state, the abdominal tenderness was diminished, there was very little sickness, but the hypogastric swelling had increased. On the 27th the evening temperature reached 102·4°, there was further abdominal swelling, but very little distress and no vomiting. The pulse had risen to 120. The question of abdominal interference arising, she was seen with me by Dr. William Duncan on the 28th, and we both took the view that it was a case of extensive cellulitis with some associated peritonitis following upon the miscarriage, and that at the moment there was no adequate indication for interference. On the 29th she was no better, and on the 30th, when I saw her, I found the vaginal swelling softer, and I thought I could detect some fluctuation. I accordingly determined, having first explored, to perform colpotomy on the following day, but prepared, if necessary, to open the abdomen. On May 1st I operated, and had the great advantage of Dr. William Duncan's presence and assistance. That was on the twenty-third day after the miscarriage, and the eleventh from the onset of her symptoms. After careful preparation of the vagina the uterus was dilated and explored, and nothing discovered. Under the anæsthetic I came to the conclusion that I could not satisfactorily reach any abscess by the vagina, and the best course to pursue was to perform cœliotomy. On opening the abdomen I found a cyst reaching almost to the umbilicus, and greatly distended. There were extensive adhesions all round the cyst wall, and some bowel and peritoneal adhesions. The breaking down of these caused considerable bleeding, and during the manipulation the cyst burst, discharging a quantity of pus. The cyst, which grew from the left side, was removed; the abdomen was flushed out with formalin solution, and then thoroughly sponged out with the same, before closure with through and through abdominal sutures. She progressed fairly for the first forty-eight hours, but on May 4th she became delirious, her pulse increased to 140, and her temperature remained at 101° and over. Her condition was so bad that it was thought useless for me to visit her, as she was for several hours unconscious. The bowel, however, responded well to an enema, and the respirations did not increase. She was having subcutaneous injections of strychnine at intervals, and nutrient enemata. On the night of the 5th she became again conscious, and still further rallied on the 6th, and though the subsequent course of her case was precarious, the temperature range showed nothing strikingly abnormal from May 14th forwards. When I saw her after a considerable interval, on June 16th, she had been up for some time, and was about to be removed for change of air.

The case is instructive, not only from the ætiological point of view, but also from that of diagnosis. It is not improbable that in some of these cases old pelvic diseased conditions, dormant during pregnancy, may be roused into activity by labour and the puerperal state, and cause infection of a simple cystoma.

(a) Read before British Gynæcological Society, July 10th, 1902.

In this case there did not appear to be anything wrong with the right adnexa. The mistake of looking upon the case as one of pelvic peritonitis with cellulitis was excusable under the circumstances, the uterus itself not being much enlarged though fixed, and supra-pubic area of dulness well localised. It is an instance of what I believe to be a safe rule (not without its exceptions) that in cases of doubt, when we have combined abdominal and pelvic signs, and when we are uncertain of being able to deal successfully with the case by colpotomy, to open the abdomen at once. Had I successfully explored this case as I intended to do with the trocar and branched dilator, I should in all probability have come to the conclusion that I had evacuated the pus from a large pelvic abscess, a conclusion which would have been followed by disastrous consequences.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held Thursday, July 10th, 1902.

Dr. Heywood Smith, a Vice-President, in the Chair.

FOUR CASES OF REMOVAL OF THE UTERUS.

Dr. F. A. Purcell showed the following specimens:—

1. A uterus with a submucous fibroid removed, for carcinoma, by vaginal hysterectomy.
2. A uterus also removed by vaginal hysterectomy after perforation of the fundus during dilatation for the purpose of extirpating the pedicle of a fibrous polypus previously expelled.
3. A uterus with multiple myomata removed by the abdomen.
4. A uterus removed for malignant disease adherent to the bladder.

The detailed notes will be found on page 83.

Dr. Heywood Smith pointed out that though the first specimen had been removed on the opinion of a pathologist that the scrapings of the endometrium indicated malignancy, this opinion had not been confirmed after the operation, and to the naked eye the tumour appeared to be an ordinary submucous fibroid assuming the polypoid form. There was a question whether there was any malignant disease or not, and if not, though, as the vagina was a small one, the operation might have been difficult, the tumour might have been enucleated and the uterus preserved. It would be interesting to know whether the curette had passed beyond the tumour and up to the fundus, or not.

Dr. Routh attached much importance to the carunculæ of the vagina being indurated, as an early indication of malignant disease higher up; if that hardness was well marked it would seem very probable that the present case was really one of malignant nature.

Dr. Purcell agreed that where, as in the case before them, the carunculæ were hard and tender, the presence of some malignancy higher up was indicated, and upon that evidence and the report upon the scrapings of the curette he had no alternative but to remove the uterus. He was quite sure that he had obtained some endometrium from above, as well as from below, the fibroid, and that the curette had reached the fundus.

Dr. Heywood Smith (the Chairman) said, in regard to the second specimen, in which the uterus had been perforated, that the fact that the woman had had nine children beside miscarriages, was of importance, as so many pregnancies were likely to weaken the uterine contractile tissue and increase the liability to perforation. Great care and very little pressure should be used in passing a sound into a uterus which had borne many children. It would be desirable for the Fellows present to give any experience they had had of perforation of the uterus; no doubt it occurred much oftener than was recorded He had himself in one case felt the sound through the abdominal wall; Dr. Meadows, a good many years ago, had a case at the Hospital for Women in which the sound was passed through the fundus; no harm happened beyond temporary pain, and neither patient was materially inconvenienced by the accident.

Dr. Routh had heard of many instances of perforation of the uterus; it had occurred twice in his own practice, but no bad effects followed. A late colleague of his had met with the same accident, and the patient died. He thought the new methods of dilatation not free from danger, though more rapid than the old-fashioned one. At the same time he had not heard of a single death due to dilatation, and in the hands of those with very large experience, like Dr. Purcell, it was a different matter from the same proceeding in those of an unskilled person, but it was a question whether it would not be better for the gynæcologist not to be so careful of his time and continue the old plan of dilatation by tents.

Dr. Macnaughton-Jones said he would like to know from Dr. Purcell if the dilatation had been gradual. He disliked the term "forcible," as applied to dilatation, as force was just what should be avoided in carrying it out. The method of dilatation was frequently indicated by the nature of the uterus we had to dilate. In the instance of a soft cervix with a patulous canal and a yielding isthmus, gradual dilatation by any form of bougie was generally easily effected, but in other cases he much preferred the plan of using an antiseptic laminaria tent beforehand, taking it straight from ether and iodoform, and subsequently—say within the twenty-four hours—completing the dilatation by some form of dilator. The tent usually enabled us readily to dilate the cervix to the circumference of the little finger before passing larger instruments. Again, the degree of dilatation depended upon the object. In some cases it was not necessary to dilate to the full extent, as exploration by the finger was not required. He had never had any accident from dilatation, by any method. Neither had he had any accident with the uterine sound. On two occasions, the sound had passed out of the uterine cavity. He had recorded this fact, but it was due to the presence of an enlarged uterine orifice of the Fallopian tube, into which the sound passed. This was due to the condition which Matthews Duncan had drawn attention to in explanation of the sound into the abdominal cavity in certain cases without penetration of the uterine wall. There was neither pain nor shock. The readiness with which the uterus could be perforated by the sound depended upon the nature of the uterine structures. All were familiar with a condition in which the uterus was frequently elongated, and in which the wall was exceptionally thin and soft, or some degenerative change had taken place. Here the greatest caution had to be observed or the sound might very easily be pushed through the uterine parietes, and the same might be said of any form of dilator. On the other hand, in a normal uterus or one with hypertrophied walls, such risk was not present. A serious question might arise as regards the responsibility of a surgeon perforating the uterus with a sound or dilator. With proper caution it was not an accident which was likely to occur save under exceptional conditions. Given a normal uterus such an accident, he was afraid, would be attributed to some rashness on the part of the surgeon, but not otherwise. It could be easily understood how a sound that was aseptic might penetrate the uterus and do but little damage. It would be different if it carried any septic material into the peritoneal cavity, and therefore the risk must, in a certain degree, depend upon the condition of the uterine canal, as the principal danger would arise from septic peritonitis.

Dr. Herbert Snow reminded the Fellows that Lawson Tait, one of their late Presidents, was the first to call attention to the rather frequent passage of the sound through the uterine wall without any bad results, and in his book on abdominal surgery he mentioned a number of cases of the kind. If the sound or dilator were sterile no harm was in the least likely to happen. Dr. Purcell might remember some ten years ago, when assisting him (Dr. Snow) to perform a ventral fixation, and at his request pushing up the uterus with a sound, the instrument passed through the wall and made its appearance below the umbilicus. It was withdrawn, the operation was proceeded with and no ill-effects whatever followed. A milder method of treatment might have answered in the present case, as in instances of rupture of the uterus in labour; the pedicle might have been removed and a gauze packing inserted.

Dr. Purcell, in reply, said that as the uterus had already expelled the polypus he had no hesitation in dilating to remove the pedicle. He had reason to suppose the pedicle to have become twisted and to be in a sloughing condition, and it could not safely be left in the cavity. If an aseptic sound passed through a healthy uterine wall, as in the case Dr. Snow had referred to, naturally no harm would result. Though he had dilated very many uteri, he had not seen many cases of perforation, and some years ago he might not have attempted vaginal hysterectomy, but have simply inserted a gauze plug for drainage. He did not know whether the uterus in this case was malignant or not, but there was a sloughing polypus outside, and the pedicle was in the cavity; it was clear that the uterus could not be considered aseptic, and therefore he performed hysterectomy. He was sure that all the Fellows agreed with Dr. Routh as to the use of tents, at all events for preliminary dilatation. In this case the os was patent; he had dilated very gradually, commencing with No. 1; there was no difficulty in introducing the early numbers, and it was No. 9 that went through the wall with the application of very little pressure. It was owing to what Dr. Macnaughton-Jones had told them when exhibiting Professor Bossi's very ingenious instrument that he had brought the case forward, as he thought that by that instrument, after preliminary dilatation by a tent, the cervix in this case might have been dilated to the required extent without accident.

Dr. Macnaughton-Jones read notes "On a Case of Suppurating Ovarian Cystoma complicating Miscarriage during the Third Month," which will be found under "Clinical Records," page 84.

Dr. Snow asked what was the strength of the formalin solution used, and what Dr. Macnaughton-Jones' experience had been as to the effects of formalin on the peritoneum. It had generally been considered a mistake to use any irritant in the abdominal cavity from fear of damaging the secretory and excretory powers of the peritoneum.

Dr. Purcell said the case was instructive as an example that in attempting to open a pelvic abscess one must always be prepared to perform cœliotomy. So also in regard to vaginal hysterectomy; he had seen a large ovarian cyst removed, after the uterus, by the vagina, and pyosalpinx taken away with the uterus, but complications were met with, and it was sometimes necessary to do the double operation. If there was any difficulty from adhesions or thickening in removing a uterus by the vagina, it was better to open the abdomen and see what one was doing. He was in the habit of using formalin in solutions of from a half to one per cent.

Dr. Macnaughton-Jones, junr., said, that with the exception of hydrogen peroxide, formalin was the least irritating of all the antiseptics in use; without any untoward effects it might be injected into the veins in sufficient strength to destroy tubercle bacilli in the blood. Its effect on the peritoneal cavity was therefore not likely to be injurious, nor, practically, had it been found so.

Dr. Macnaughton-Jones, in replying, said that the uterus, as he had stated, was fixed. There was no question of diagnosis, except that of pelvic suppuration, which was negatived by the discovery of the ovarian cystoma. The case was a very puzzling one, as there was no indication whatever of any uterine complication, all the products of gestation had completely come away, and the gradually increasing swelling closely resembled the spread of perimetritic inflammation. With regard to the question of formalin, he had for some years been in the habit of using it constantly in solutions of from 1 in 2,000 to 1 in 5,000, for a variety of purposes, and had never had the least ill effect from it. Used in proper strength he believed it to be the most perfect and harmless antiseptic we could employ.

For Dr. Purefoy, Master of the Rotunda, Dr. Macnaughton-Jones, junr., read notes (with specimens) of (1) "Tubes and Cystic Ovaries from a Rudimentary Uterus." (2) "Secondary Growth from the Abdominal Cicatrix after Hysterectomy," which will be found on page 80.

Dr. H. R. Hodgson read a paper on "A Case of Double Pyosalpinx removed after Seventeen Years' Suffering," which we hope to publish in an early number.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION.

Meeting held Friday, July 11th, 1902.

Dr. Macintyre, President, in the Chair.

Dr. Wyatt Wingrave read notes of a case of

BILATERAL ADDUCTOR PARALYSIS

in a boy, æt. 7.

Mr. Lennox Browne inquired if adenoids were present, or any symptom pointing to reflex disturbance?

Dr. Dundas Grant said he had seen the patient, and found the larynx normal in every respect. He regarded the case as one of hysterical aphonia.

Dr. Dennis Vinrace asked if there had been a tendency to relapse?

Dr. Wingrave, replying, said he had removed adenoids; one application of the interrupted current quickly restored the voice.

Mr. Lennox Browne read notes of a case of

KERATOSIS OF THE TONSILS

without leptothrix in a young adult. He had removed the tonsils, of which Dr. Wyatt Wingrave now showed microscopic sections.

Dr. Wingrave described two varieties of tonsillar keratosis, one in which the horny growth projects through the open mouth of the crypt; the other where, the orifice being closed, the horny epithelium forms a "perle" in the lacuna.

Dr. Dundas Grant remarked that the condition is apt to disappear without apparent cause.

After some observations by Mr. Chichele Nourse, Dr. Jobson Horne, and the President, Mr. Lennox Browne and Dr. Wingrave replied.

Dr. W. H. Kelson showed a case of

TUBERCULOUS TRACHEITIS.

The patient, whose two brothers died of phthisis, has congestion of the larynx and ulceration at the upper and anterior part of the trachea. The sputa contained quantities of tubercle bacilli.

Dr. Kelson also read notes of a case of singer's nodes on both cords in a choir-boy.

Dr. Dundas Grant showed a case of

CONGENITAL PAPILLOMATA OF THE LARYNX

in a girl, æt. 23, who had worn a tracheotomy tube from infancy until the time she consulted him four weeks ago. Her voice then resembled that of functional aphonia. The lips and tongue moved, but there was no phonation. Dr. Grant removed the papillomata with forceps and snare, and cleared the larynx, so that the patient was able to breathe through the natural channels. Later he closed the tracheal wound. The patient has now a fair voice.

Mr. Lennox Browne congratulated Dr. Grant upon the result. The patient, who was before voiceless, can now utter a good vowel sound. He could recall only one similar case. In that instance it was some time after the removal of the papillomata before the patient was able to speak.

Dr. W. H. Kelson pointed out that the case was evidence in support of the view that tracheotomy alone was not curative in cases of papillomata of the larynx.

After a few remarks by the President, Dr. Grant replied.

Dr. Dundas Grant showed a bent glass tube of a form devised by Dr. Leduc, of Nantes, for enabling a patient to apply powders to his own larynx.

The President showed (1) Photographs of the new electrical department at the Glasgow Royal Infirmary. Besides apparatus for X-rays and high frequency currents and a very large static machine, there is a huge and very powerful electromagnet for removing foreign bodies from the trachea, &c. (2) Photographs of a case of cancer of the nose in a woman, æt. 60. Two months ago an old wart took on a very rapid growth. On removal of the external mass it was found to have penetrated the cartilage and to be invading the tissues inside the nose. The case is now under treatment by the X-rays.

Berlin, July 19th, 1902.

Resorbent Pills (Ichthyol Salicylate Pills).

A communication by Dr. B. Rohden appears in the *Therapeut. Monatsch.* du Ichthyol Salicylate ; " 50 per cent. pills ichthyol salicylate is a new compound made by the Ichthyol Gesellschaft at the author's suggestion. These pills have an extraordinary power of resorption, it is said, that make them of great service in commencing atrophic processes and for relief of inflammation in various organs. In tuberculous affection of the lungs, in old pleuritis and in the treatment of rheumatic and other arthritic affections they are said to be valuable. Ichthyol has the property of contracting blood vessels and in combination with salicylic acid, which also has this property in small doses, its value is enhanced. The pills have also been used with good effect in Bright's disease and in diabetes. The author recommends that a little effervescing alkaline water be drunk at the time the pills are taken. In the case of uric acid arthritis the treatment may be continued almost for indefinite periods with brief intervals of rest. One pill three times a day should be the initial dose, and this may be increased and should be on occasion to three thrice daily. The author claims that this preparation will bring about a *restitutio ad integrum* in cases of subacute and chronic inflammation, and where contractions are going on. The ichthyol salicylate combined with a suitable soap may be also used for inunction.

Peritoneal Adhesion after Laparotomy.

A paper by Dr. Karl Vogel appears on this subject in the *Discu. Ztech. f. Chir.* The occurrence of five cases in the practice of Schede of recurring adhesive peritonitis, four of which proved fatal from ileus, led the author into a special study of the subject. He first gives the history of the five cases, and then goes on to the question of the ætiology of the peritonitis, which he attempts to clear up by aid of animal experiment. Certain factors were found in the experiments named, and placed in the following order: (1) hæmorrhage from intraperitoneal wounds; (2) mechanical irritation and injuries, especially when they are near the laparotomy wound; (3) cauterisation, especially when it has been so intense as to prevent union by first intention, the eschar acting as a foreign body; (4) foreign bodies; (5) chemical irritations; (6) infections. He then endeavoured to indicate the most suitable measures to be adopted in order to avoid these dangerous adhesive inflammations. The most important measure is to avoid allowing the intestine to remain still, a thing which always threatens when the abdomen has been opened, and especially when the adhesions have existed before. For the occurrence of such adhesion it is first of all a condition that two opposing surfaces of intestine shall remain quietly in contact with each other for some time, and to avoid this the intestines must be kept on the move. With this object he gave the animal operated on and in the case, a young girl, physostigmin salicylate commencing soon after the operation. The medicine was given subcutaneously, and for the first three days after the operation, the result being good. It is also advisable in the human subject to change the patient's position early and frequently; animals make these changes of themselves, and the effects of them are good. Massage also should be begun as soon as circumstances allow, in order to do away with any ill-effects following from adhesions that may already have taken place. A further measure is the prevention of contact between different parts of the abdominal contents by filling the abdomen with a suitable fluid, and particularly about the abdominal wound. According to the author's experiments, the most suitable fluid was a solution of gum arabic in common salt solution. Mucin also possessed some useful properties, but it decomposed too rapidly. His experiments with physiological solution magn. sulph. and white of egg albumen were not successful.

At the Medical Society Hr. Karewski brought forward the subject of

Diffuse Adhesive Peritonitis after Appendicitis.

Such peritonitis was generally limited to the parts adjoining the appendix, but although rare general peritonitis might occur, and it was very dangerous. The clinical symptoms were mostly disturbance of function which might go so far as to represent chronic or subacute ileus. During the past ten years he had had thirteen cases of adhesive peritonitis. Three cases of total obliteration of the abdominal cavity following perforation not operated on; an artificial anus was made in two cases, but all died in a short time.

Four cases of appendicitis that at first appeared to be doing well after operation. One case died. In the three other cases the adhesions were so extensive as to justify the expression " general adhesive peritonitis."

Two cases of doubtful ætiology. In one, the case of a boy, tuberculous peritonitis was the diagnosis, but only a general adhesive peritonitis was found, the adhesions being thickest around the vermiform appendix. A girl had bladder disturbances a long time, the significance of which was long in being made out. The boy died; the girl recovered.

Two cases with long-standing fistula. Both cases were operated on, but died.

The most certain way of avoiding these forms of peritonitis is to remove the appendix as early as the case admits, when it has once become the centre of suppurations.

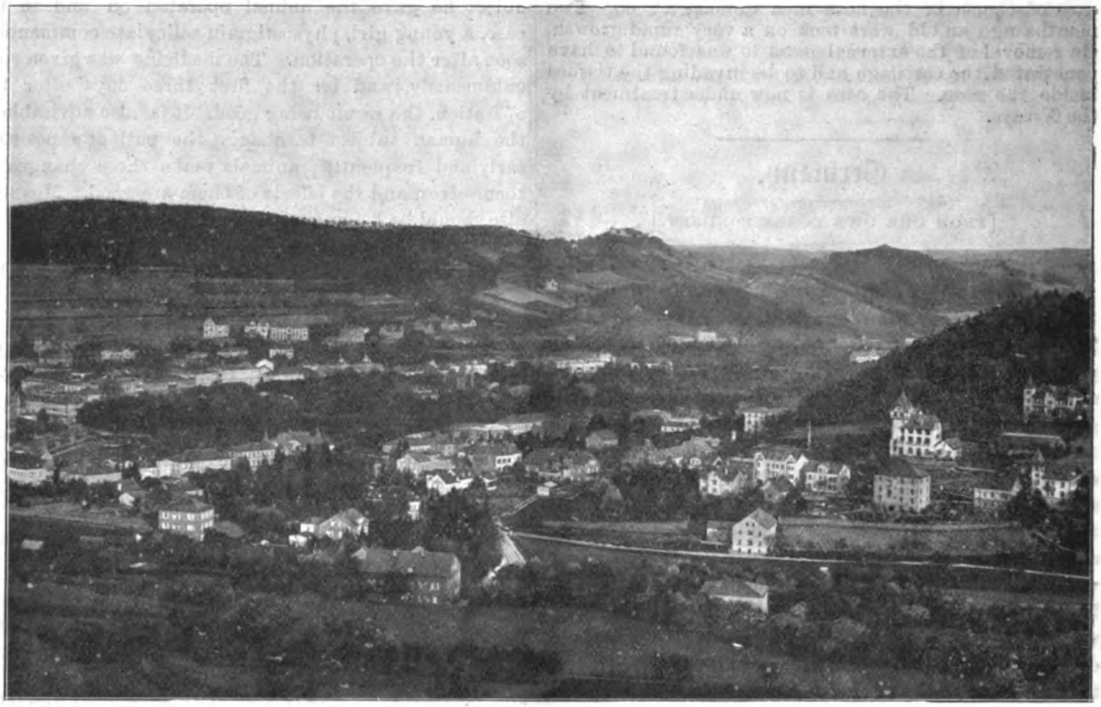
Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, July 19th, 1902.

Pharyngotomy.

At the " Gesellschaft der Aerzte," Büdinger showed a male patient on whom he had operated for cancer of the throat, by removing the epiglottis and contiguous parts. He related Heindl's experience, who performed an endo-laryngeal operation for a similar condition with unhappy results. Büdinger said that he commenced by having a tube inserted into the stomach through the nose, but this caused such a catarrhal and even purulent discharge, that it had ultimately to be withdrawn.



After this the patient soon learned to draw the open parts together, and so fix the hyoid bone with the surroundings that deglutition could be carried on without an instrument. Taste was unaffected, although the voice was irreparably lost.

The prognosis of this operation is not encouraging, as only thirteen cases of epiglottal carcinoma were placed on record, ten recovering, while three died. These cases were simple epiglottal, but if the surroundings were involved the results were more pronounced, such as in eleven cases, where seven died, while four recovered.

Eiselberg said that he has operated for cancer of the epiglottis by extirpating the larynx altogether with perfect success. In one case he had a recurrence where one of the glands that had become infiltrated was left and formed a centre for recrudescence. He disagreed with Büdinger as to tracheotomy being a prophylactic. He believed also that the nasal tube was a bad practice, as it produced rhinitis at a very early period.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

KISSINGEN.

The new management, inaugurated last year at Kissingen, has proved itself efficient and successful. This year the season commenced, and has continued, with a throng of patients and visitors largely in excess of prior seasons, and the high social rank of many of its guests is in accordance with its title of "Royal Baths of Kissingen."

The improvements introduced are visible everywhere—in the Baths, the Royal Kurhaus Hotel, the Kurgarden, and the town. All around the place progress predominates, and promises increasing popularity and prosperity. The picturesque vicinity of the town is much in its favour. Excursions on all sides offer attractions to tourists. The fishing facilities are well known to the disciples of Izaak Walton, the river Saale (running by the town), having a good supply of pike, barbel, chub, &c.; while ten miles away, at Neustadt, is excellent trouting. Fishing is a favourite amusement here.

The indications for treatment at Kissingen are dyspepsias of all kinds, gastric catarrhs, liver maladies, spleen stoppages, abdominal disorders, obesity, fatty heart, scrofula and habitual constipation. To these some German authorities add gout, rheumatism, anæmia, and pulmonary complaints.

Of the many mineral springs, three (the Rakoczy, the Pandur, and the Maxbrunnen) are used for drinking; and two (the Soolsprudel and the Schoensbornsprudel) principally for bathing.

The Rakoczy is the spring which has chiefly gained for Kissingen its renown. This water is usually drank in the morning, fasting, in glasses of 250 grammes, and is generally taken cold. The quantity prescribed varies according to the malady and the patient's condition. For stomachic affections four glasses are considered sufficient; for difficult digestions, hepatic congestion and obesity, eight glasses, *i.e.*, four before breakfast, and four in the evening, either before or after dinner. Between each glass of Rakoczy water it is advisable to promenade for fifteen minutes.

The Maxbrunnen Spring is also exclusively employed for drinking. It is preferred for children to the Rakoczy; drank alone or mixed with the milk of cows or goats.

The Maxbrunnen is much preferred for scrofula. It is then taken, fasting, in the morning (the doses varying according to age) from one to four glasses. Again, at ten o'clock, one or two glasses; and in the evening one or two glasses of the water added to half the quantity of goat's milk. Some think a better effect is produced by drinking the Rakoczy in the early morning and the Maxbrunnen at ten o'clock and in the evening.

In addition to baths of the Soolsprudel and the Schoensprudel, there are given at Kissingen mineral mud-baths and mineral gaseous baths. And here are also a variety of hydrotherapic arrangements, pneumotherapic cabinets, inhalation rooms, vapour baths, &c. The baths are mainly relied upon for lymphatism, scrofula, skin diseases, gynæcological cases, and habitual congestions of the nervous centres.

The season runs from April to October; and as an "after cure" the resident physicians find the neighbouring iron-water springs at Bocklet efficacious.

These springs at Bocklet are amongst the finest chalybeate waters of Europe. The temperature at Bocklet is unusually equable and the atmosphere highly ozoniferous. For anæmia and hysteria this small health-station is strongly recommended, and for convalescents generally.

OPENING OF THE NEW OCHIL HILLS SANATORIUM.

ON the invitation of the Directors of the Sanatorium a large and representative company of ladies and gentlemen were conveyed by special train from Glasgow, on the 16th inst., to Milnathort, where a large number of brakes were waiting to take the company to the Sanatorium some distance off. Among those present were Sir Thomas Glen Coats, Surgeon-General Pinkerton, Professors McCall Anderson, Glaister, and Murdoch Cameron, Dr. Ebenezer Duncan (chairman, Board of Directors), Mr. Quarrier (of the Bridge of Weir "Homes"), Dr. Fraser (Paisley), Drs. D. C. McVail, Alex Robertson, T. K. Monro, Thos. Laprink, D. Tindal, A. S. Tindal, J. Hamilton, D. Couper, W. Frew, Thos. Richmond, &c., &c. On arriving at the main entrance to the Sanatorium, Dr. Duncan, in a short but graceful speech, extended a very hearty welcome to the visitors. Thereafter Dr. Fraser, in a few appropriate and neat remarks, presented Miss Coats, in the absence of her mother, Lady Glen Coats, from indisposition, with a beautiful key of unique workmanship, and a facsimile of one found in Loch Leven, which has much historical or legendary interest attached to it. Miss Coats, key in hand, then opened the door and allowed the large company to go on a visit of inspection through the whole of the Sanatorium, which is extremely well-equipped with every appliance for the treatment of tuberculosis. The inspection over, the company, to the number of 200 to 300, sat down to a *recherché* luncheon, over which Dr. Duncan presided. Several toasts were proposed, which called forth some good speeches from the Chairman, Professor McCall Anderson, Surgeon-General Pinkerton, and others. The Sanatorium has been built at a cost of £35,000, and occupies one of the finest sites in Europe, and will probably compare very favourably with Sir Lauder Brunton's Model Sanatorium, recently described. The Ochil Hills Sanatorium has been specially built for its purpose on an elevated plateau having a dry and gravelly soil, 800 feet above sea level, and has its exposure to the south. It comprises sixty bedrooms for patients, with the windows opening quite noiselessly to the outside and allowing the rooms to be flooded with air and light; at the same time the window frames are a protection against strong winds. Balconies are dispensed with, so as to ensure the very free access of air and light to the rooms, all of which communicate with long and spacious corridors. The grounds extend to 460 acres, and the surrounding scenery is picturesque and grand. The county in which the sanatorium is situated has the smallest death-rate from pulmonary consumption of any county in Great Britain. For treatment the equipment of the Sanatorium includes an inhalation room, provided with an electric motor for driving the spray apparatus, and an electrical room with an installation comprising a powerful Röntgen ray and high-frequency current apparatus, and an induction coil arc lamp for ultra-violet light.

The Sanatorium is now ready to receive patients, of whom, we understand, a number have been booked for some time. Apparently it is going to meet a much-felt want.

The Operating Theatres.

TOTTENHAM HOSPITAL.

ABDOMINAL MYOMECTOMY.—Dr. A. GILES operated on a woman, æt. 41, who had been admitted on account of an abdominal tumour. This interfered greatly with her occupation, which was that of a hospital nurse, and it also caused her a great deal of pain. The tumour was very hard and a diagnosis of myoma was made. On opening the abdomen the tumour was found to consist of a large pedunculated myoma springing from the anterior aspect of the fundus; as there were no other growths it was decided to leave the uterus and to remove the tumour alone. Accordingly an incision was made round the pedicle and the attachments of the tumour enucleated. The peritoneal flaps were brought together by interrupted mattress sutures, after which the peritoneal edges were sewn over with a continuous suture of fine silk. The uterus was fastened under the abdominal wound with the object, as the operator remarked, of rendering the uterine wound easily accessible in the event of any hæmorrhage occurring. The abdomen was then closed in the usual way. The tumour was the size of a fœtal head, and on cutting into it, it showed extensive cystic degeneration in its central portions. Dr. Giles remarked that sub-peritoneal myomata were especially prone to degenerative changes, which together with pressure on adjoining organs constituted the two chief complications of this kind of growth; in contradistinction to this, the chief troubles caused by intra-uterine myomata were hæmorrhage and septic absorption due to sloughing and to infection through the vagina. The operation he had just performed was a typical example of the procedure of abdominal myomectomy in the sense in which he had recently defined it (see the report of a case of abdominal hysterectomy for myoma in THE MEDICAL PRESS AND CIRCULAR, July 16th, 1902), in contradistinction to the two methods of removing myomata from the substance of the uterine wall and from the uterine cavity respectively. All three were conservative procedures. It was not always possible to tell before commencing operation which plan would prove the most suitable, but there were, he considered, certain general indications that might serve as a guide: thus, with a large smooth uterus whose general shape was like that of a pregnant uterus, and when hæmorrhage was a prominent symptom it was probable that the case would lend itself to an abdominal hysterotomy; when the hæmorrhage was a less prominent feature and the smooth outline of the uterus was interrupted by one or two prominent bosses, it was likely to be a case for enucleation, but when there was no unusual hæmorrhage, and a tumour could be felt tolerably distinct from the uterus, a myomectomy might be contemplated; lastly, when multiple growths were present it was unlikely that any of these conservative methods would be applicable, and hysterectomy would probably be required.

Convalescence in this case was somewhat delayed by an abscess in the abdominal parietes, which was attributed to an infected suture; the abdominal wall in this woman contained an unusual amount of fat of low vitality, which conduced to this result. The abscess cavity healed up without causing further trouble; the patient then made an uneventful recovery.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 23, 1902.

THE MENTAL RESPONSIBILITY OF CRIMINALS.

Penal legislation always lags far behind the progress of psychology, and perhaps it is well that it should be so, since the data afforded by this science are often open to criticism. Nevertheless the punitive theory of punishment has undergone very considerable modification during the last few decades, and a more scientific and social spirit has been infused not only into our penal legislation, but also into the judicial administration thereof. To assert that the conception of right and wrong is an extremely variable quantity as between the individual units of a community is to formulate a truism, but the inevitable corollary of this view is that individual responsibility is subject to precisely similar variations. The limits of these variations are extremely wide, between an ideal conception of duty on one hand and the irresponsible lunatic on the other—and there is no strict line of demarcation between the obviously irresponsible and those who may be termed the quasi-irresponsible. Wherever we meet with instances of the commission of grave crimes for obviously inadequate objects this partial absence of the moral sense forces itself upon our notice, and in the thoughtful excites disquieting reflections. It is especially in murder cases that the lack of proportion between the crime and the motive is most striking, and the very magnitude of the crime creates a suspicion of an initial and fundamental defect of mental equilibrium. To take concrete examples: when a man assassinates a bank manager in order to obtain possession of a large sum of money we may conclude that the man is an intelligent criminal; but when, as so often happens, a man of low intellectual calibre, in a fit of maudlin jealousy or disappointment, wantonly kills under circumstances which render his immediate arrest a matter of certainty, surely this fact is presumptive evidence of a disordered mind. Society possesses, and is entitled to exercise, the power to prevent the latter class of criminals from jeopardising the harmony of social life, but to inflict the death penalty merely because the crime took the form of murder is illogical and scientifically unjustifiable. These reflections are prompted by several recent trials for murder in which a verdict of guilty was followed by the capital sentence, although most medical men would not hesitate, on reflection, to conclude in favour of what we may term a mitigated responsibility. The mischief arises from the popular conception that moral irresponsibility is necessarily associated with some other outward and visible manifestation of mental disease the brain a single complete organ, instead of a composite structure any department of which may be functionally defective without involving the other centres or group of centres. Moreover, if sanity may be defined as a state of harmonious equilibrium between the higher nerve centres, insanity and the various degrees of deficiency in the moral sense may be defined as manifestations of a lack or disturbance of that equilibrium, and this entails a modification of the penal responsibility in the individual case. The logical outcome of these arguments would be the obligation on juries and judges to take account of the apparent motive of the crime, marked want of proportion between the cause and the effect being accepted *per se* as evidence of a partial absence of responsibility. In reality, we are only arguing against the routine infliction of the death penalty for murder, for it would remain none the less necessary to place such individuals under restraint in the interest of society at large; in other words, we would plead that the spirit which now animates the treatment of confirmed inebriates, regarding inebriety as a disease rather than a crime, should be extended to offences of greater magnitude.

BATHS FOR THE PEOPLE.

"THE Englishman's tub" is almost a national institution. The average Englishman considers his morning bath an essential part of his daily toilet. Probably in no other country is the importance of thorough ablution more clearly recognised. A bath-room is a necessary part of every modern house. Most English hotels provide elaborate arrangements for bathing. But while England generally is considered to be in advance of most European countries in bath provision, we are far behind the ancient Romans, who elaborated bathing from a hygienic necessity into a wasteful and enervating luxury. But even in this country the habits of bathing are to a great extent of recent development. In London and in most of our ancient cities many of the best houses built in the eighteenth century and earlier part of the last century are devoid of bath-rooms or altogether inadequately supplied with accommodation for bathing, and facilities for perfect cleanliness among the poor are still meagre and insufficient. Of recent years the movement to provide "people's baths" has been quickly growing and gathering force. To erect swimming baths is an expensive matter, which of necessity can only be accomplished by municipal or collective action, and hence such are almost confined to those districts where large numbers of people congregate. But the provision of spray and shower baths can be met at a comparatively small outlay, and is well within the means even of a small parish. Undoubtedly the most suitable bath for cleansing the working classes is the spray and shower bath. Such have been provided by many employers of labour in connection with their mills and factories. Mr. Walter W. Thomas, in the current number of the *Public Health Engineer* (July 12th, 1902), shows that the shower and spray bath originated in Germany; the first establishment to attract attention was erected in the barracks of the Kaiser Franz Grenadier Regiment of the Guard in Berlin in 1878. It cost £200, and was capable of bathing 300 men per hour. The term "People's Baths" in the United States is generally known to refer to public baths which are provided with spray and shower, but having no swimming, bath. Such have been constructed in many German and American cities. We hope England will quickly follow such excellent examples. Already shower and spray baths have been introduced into several existing and new public baths, and we understand the Liverpool Corporation have erected in one of the poorest districts of the City, and in close proximity to the docks, a complete installation of people's baths. In Lord Rowton's model lodging-houses admirable baths are provided at a very small charge, and the use of the foot bath is allowed without additional payment. We could wish that in connection with all municipalities, and even in country villages, simple shower and spray baths could be provided for both sexes. Perhaps the day will not be far distant when our excellent metropolitan lavatories will be able to add this additional hygienic agent to their outfit, thereby supplying another valuable influence making not only for comfort but for health. Undoubtedly the provision of people's baths affords the best means of securing greater cleanliness at a minimum of expense. We commend the movement to the careful attention of all humanitarians and hygienists.

THE LIFE-COST OF THE PANAMA CANAL.

IT has been suggested in some quarters that young Englishmen might find it worth their while to go out to the isthmus when the United States Government starts operations on the works it has recently acquired from the French company, as Americans show no inclination to face the fever-stricken climate of those parts. Though the danger is nothing now to what it was when the enterprise was initiated by the original company, the climate is in no way suitable to the average European, and less so to the full-blooded, athletic Britisher than to any other. It is, of course, when the bush is being cleared and the virgin soil disturbed that the danger of yellow fever is greatest; the early days of the canal offer a striking example of this. At that time every train run to the various sidings had an empty waggon at the end, into which the dead were thrown as they were found along the permanent way. At Colon niggers and Chinamen would crawl down at night and sleep on the beams under the shipping wharves, and in the morning it was no unusual thing to find several of them dead. It is said that every sleeper of the American Trans-Isthmian Railway cost a life; this is probably only a picturesque exaggeration, but reduced to truthful proportions the facts are appalling enough, and the cemetery at Monkey Hill, a few miles outside Colon, is eloquent as to the expenditure of human lives involved in the starting of this great enterprise. These considerations weighed not a little with the United States, in deciding the Government to purchase the Panama works, rather than to start another canal, which would have meant the opening-up of new country with all its attendant evils. But even to-day yellow fever is endemic in Panama, and hardly a week passes during which there are not two or three deaths from this disease, mostly among foreigners, especially among new arrivals. Malaria in its worst forms exists all the year round throughout the isthmus, and indeed all along the coast of the Caribbean Sea. The climate is damp and enervating, and the heat overpowering. Moreover, Panama and Colon, respectively on the Pacific and Atlantic sides, are hemmed in by bush, there are no roads for rides, drives or walks; the day's work over there is nothing to do, nothing to see, and the lonely man seeks the gaming or drinking saloons out of sheer ennui. Salaries and wages run high, will run higher still in the near future, but at their highest will hardly be in proportion to the expenses of ordinary life and the risks involved. It is not astonishing to hear that the average American is not disposed to exile himself to such a place, but

great as is the bond of good fellowship which unites us to our Transatlantic cousins, where they are reluctant, it is surely not reasonable to encourage Englishmen to tread, and it would be folly to build up with English lives an enterprise, however great of which in the future the United States alone will reap the benefit.

Notes on Current Topics.

A Physicians' Corner for Westminster Abbey.

The healing art is carried on in silence, and much necessarily in secrecy. Practitioners of medicine have always shunned mere meddling praise. Doctors, although valued in private life, have rarely taken a prominent part in public work. The profession has ever been jealous of its reticence, and always looks askance at any movement which seems to seek a success necessitating the gaining of public opinion. Court recognition or national approval until recently has been but exceptionally bestowed. In the press or on the platform medicine but rarely claims a place. Even now any attempt to lead popular opinion except through professional channels is often discouraged. The leaders of the profession have ever been slow to countenance efforts seeking to raise the status of practitioners and to accord to members of the profession national recognition. And this spirit of effacement has had its effect. The nation has been slow to recognise the value of the services of those who accounted their own services lightly. Divines, warriors, poets, musicians, and men of letters have ever been accorded a high place in the nation's esteem, but the representatives of medicine have until recently received scant honour. This is strikingly evidenced by a reference to such a work as that just published by Mrs. A. Murray Smith, "The Roll Call of Westminster Abbey." The Abbey is the revered Shrine of England's honoured dead. But among the illustrious dust there are but few who once might have exercised the divine right of healing. There is no Physicians' Corner at Westminster Abbey. Monuments to physicians are few and far between. In the south transept is a cenotaph to Sir John Pringle, the favoured Court doctor of George II. In the north choir aisle is a monument to John Plenderleath, who was physician to the forces in the field under Wellington. Edward Wetenhall, another medical man, lies by the side of his father, the Bishop of Kelmore and Ardagh. Dr. Woodward, whose name is kept in remembrance at Cambridge in connection with the Woodwardian Museum, lies buried in the nave close to the illustrious Newton. Thanks to the efforts of the lovable Frank Buckland, the remains of the great John Hunter sleep in the silence of the Abbey. In St. Andrew's Chapel is the bust of John Hunter's nephew, the great morbid anatomist, Matthew Baillie. Thomas Young, although chiefly remembered as a physicist, was also a physician, and Chantrey's beautiful medallion stands for his record. Mead, the great physician of George II., also rests in the Abbey. There is also a bust to Sir James Y. Simpson, the introducer of chloroform. And it must not be forgotten that Charles Darwin, the great biologist, lies near Herschel and Newton. But when all are told the memorials which medicine can claim are comparatively few and meagre. We venture to think that both the profession and the public in the coming years will realise more clearly the duty and privilege of granting honour to those to whom honour is due.

The Health of Schoolgirls.

The schoolgirls of to-day will be the mothers of tomorrow. In the maintenance of national efficiency *puellaculture* should play a leading part. Arguments have recently been advanced for "a periodical stocktaking of our children throughout the country." If this could only be carried out on scientific lines much good might be accomplished. In these days of strenuous educational efforts it is most necessary that trustworthy data should be forthcoming regarding the influence of school life upon the health of girls. Dr. W. B. Drummond deals with this subject in the current number of the *Scottish Medical and Surgical Journal*. It is interesting to note that the only years in which the death-rate of females is as great as that of males are those in which girls are at school and those immediately succeeding the period of school life, in which any evil effects of school life would become manifest There are great discrepancies in the statistics relating to sickness in schoolgirls. Mrs. Henry Sidgwick some years ago sought to procure accurate health statistics of women students at Cambridge and Oxford. She gives the following percentages of English girls as being in poor or indifferent health: 3 to 8 years of age, 11·57; 8 to 14 years of age, 10·13; 14 to 18 years of age, 10·89. There are grounds for believing that permanent damage may be wrought when at the appearance of puberty excessive strain is often thrown on the system by the objectionable cramming methods of our educational system. No one can doubt but that much in our secondary and collegiate courses of training go far to unfit girls for their high office of wives and mothers. Certainly the girl athlete of to-day is doing her best to reverse matters, at least as regards physical disability. In studying this matter much help will come from adopting the view of Geddes and Thomson in their work on "The Evolution of Sex," that the female is characteristically anabolic, while the male is as distinctly katabolic. In securing hygienic school-life for girls attention should be given to nutrition. Periodical weighing and measurement should be adopted in every well-conducted school. Much care should be given to the regulation of physical exercise. Suitable clothing both for ordinary wear and for exercise should always be provided. Abundance of interesting occupation and a healthy mental environment with plenty of rest between the periods of activity is of the utmost importance.

Social and other demands should not be allowed to disturb the proper periods for sleep. In the case of school boards it is certainly well that boards of management are now realising the importance of appointing medical men to act as examiners and advisers in all matters affecting the health of the school children. There is need for much research in the rapidly evolving science of school hygiene.

Medical Aid in India.

With a growing realisation of the responsibilities of Empire, and a righteous pride in the might and majesty of our Indian possessions, it is well that those at home should be acquainted with the means available for meeting the necessities of the diseased. Although busy in the maintenance and extension of our British hospitals and their medical schools, it is necessary that the requirements of our own dominions beyond the seas should not be forgotten, and in no ways neglected. Sir Richard Temple, in his new work on the "Progress of India, Japan and China in the Century," shows that there are something like 1,300 hospitals and charitable dispensaries scattered through the 250 administrative districts into which British India is divided. They receive about half-a-million of indoor patients in a year, and afford outdoor relief to many millions. Despite any prejudices which they might be supposed to have, the natives appear to confide in, and to highly prize, European advice and medicine. Of European surgery they have the highest opinion. It is particularly interesting to notice that the opening of dispensaries on the remote Frontiers among wild tribes has always been found to have a good effect politically. Sir Richard Temple further shows that these institutions, while illustrating Western science and charity, also afford a wide scope for the work of native medical practitioners among their own countrymen. Vaccination has proved so beneficial that practically no objections have been raised among the native community. But, in spite of much progress, the public health of India can hardly be considered good according to European standards. The death-rate varies much in different districts and in different years, ranging from 22 to 25 per 1,000, and not infrequently rising to above 30 per 1,000. Evidently India still presents a wide field for the sanitarian and for the teacher and practitioner of medicine.

The International Congress for the Welfare and Protection of Children.

The very successful Congress held during the past week is the third of what we trust will be a long series. The former gatherings were in Florence and Buda-Pesth. The present Congress met under the patronage of the King and the presidency of Earl Beauchamp. The medical section was directed by Sir James Crichton-Browne, who delivered a valuable address on Physical Efficiency in Children, of which we give a full abstract in another column. In this the author maintained that, as compared with America, we were lagging in the scientific pursuit of measures to secure the highest welfare for the child life of the nation. Numerous subjects of medical and hygienic interest were considered. Dr. John F. J. Sykes urged the necessity of securing hygiene and sanitation in the home and at school; Dr. Francis Warner dwelt on the principles directing the physical training of children; Drs. Shuttleworth, M. W. Barr, Fletcher Beach, and J. Milson Rhodes discussed the management of imbecile, feeble-minded and epileptic children; Dr. Kelynack opened the discussion on infant life protection. A large number of papers were discussed in the legislative and educational and philanthropic sections. Earl Beauchamp held a reception at the New Gallery; Dr. and Mrs. Shuttleworth gave a garden party at Richmond; and visits were also made to the Royal Normal College for the Blind, Redhill Reformatory, Earlswood Asylum, Hanwell School and Holborn Union Schools. A dinner to the delegates was also given at the Savoy by Commendatore A. Scander Levi. The Congress will have done much to further the interests of child-life in this and other countries. We understand the next Congress will probably meet in Berlin.

A New Classification of Hospital Patients.

In the proposed new civic hospital for contagious diseases in Montreal the patients are to be classified in a novel manner, the grouping being arranged on the basis of religious affinities, irrespective, possibly, of their morbid characteristics. It is sad to think that sectarian differences follow patients even into small-pox hospitals, and we can only hope that theological considerations will not be accorded undue influence in respect of treatment. The next step will be to classify drugs as Catholic and Protestant respectively, so that no confusion shall be possible.

Chinese Medicine.

As everyone knows, the practice of medicine in China at the present day presents a simple farrago of nonsense and superstition. Such things as wasps' nests, powdered human skull, earth worms, and other abominations, animal, vegetable and mineral are prominent among their drugs. After all, we need not go back a couple of hundred years in Western pharmacy to find physic compounded freely from materials no less grotesque and revolting. Indeed, when we take the scientific remedial treatment of to-day we see it is derived from sources that are not altogether unlike the ancient haphazard conditions whereby our ridicule is provoked. The difference is mainly one of superior chemistry, which enables us by the use of active principles and extracts of various animal and vegetable substances to substitute the precision of the rifle for the diffuse inaccuracy of the blunderbuss. As to surgery in China, it is chiefly conspicuous by its absence, and appears to consist chiefly in vigorous mechanical counter-irritation. It is to be hoped, therefore, on the score of humanity, that modern scientific methods may replace the existing barbarous medical practice among the Chinese. Japan has assimilated the whole range of Western scientific medicine and surgery with an adaptability little short of marvellous. To such a degree has this process been carried that some of the great modern discoveries in bacteriology have hailed from that country. The Japanese are credited with the desire to introduce scientific medical practice into China. Should Western methods of education be adopted in China, which shows some inclination to take that step, it is likely that a new race of medical practitioners will be an early outcome of the movement.

Mr. Herbert Spencer on Euthanasia.

Mr. Herbert Spencer's recent and, as he promises us, his last work, is unfortunately hardly likely to enhance his reputation. His suggestion respecting euthanasia is we fear one which, should he attempt to carry it into practice, would quickly make him liable to prosecution by the admirable society for the protection of animals from cruelty. It has occurred to the eminent philosopher that "by centrifugal force the cerebral circulation might easily be regulated." A person placed with his head in the centre of a table capable of being made to revolve on its axis, a moderate speed of rotation would cause abstraction of blood from the head and determination of it towards the feet; while, contrariwise, if the feet were placed in the centre and his head at the circumference, his head would become congested. It has occurred to Mr. Spencer that "the fatal result quickly entailed on a patient so placed, even when the velocity of rotation was moderate, was a fatal result, which might intentionally be produced where the death penalty had been pronounced." And we are told that "there would thus be provided for them a simple means of euthanasia." Mr. Spencer, we learn, entertained the thought of having the experiment tried at the Home for Lost Dogs, but either through the discouragement of his anti-vivisectionist friends or from other causes his idea was never carried out, and now it is published "in the hope that some one with adequate time and means will do that which I was compelled to leave undone." We sincerely hope that no one will be so foolish as to dabble in such disreputable "euthanasia."

Rational Clothing in Hot Weather.

The heat of our English "two days and a thunderstorm" gives rise invariably to the annually recurring discussion as to the need for rational clothing. With the rapidly occurring climatic variations it is sometimes difficult to quickly adopt a change in garments. The tendency is, however, becoming more marked to adapt dress to climatic requirements, and present day attire is perhaps more sensible than in any previous period. There is, of course, much to learn and much to do if sound hygienic principles are to prevail in the matter of clothing. While the private individual is more or less fettered by custom, fashion, and financial restrictions, the public officer, such as the policeman, the postman, and the soldier, is still to a large extent bound down by cast-iron fetters of law or entangled by red-tape regulations. The other day the question of postmen's clothing was raised in the House of Commons, and we think it would be well that the whole matter of official clothing should be carefully considered and fully investigated, and not merely be raised during the enervating season of highest summer temperatures. There can be but little doubt that health might be better preserved and disease rendered less serious if some of our public servants were provided with clothes more suited to the character of their work and permitting of speedy modification to meet the rapidly-occurring alterations of our summer days.

Sunday Baking.

Under the most favourable circumstances the baking of bread cannot be considered a healthy occupation. Indeed, the whole class of bakers would with little hesitation be relegated by an actuary or a medical examiner to the list of "bad lives." For many years past sanitary reformers and legislators have laboured to render the lot of the journeyman baker more tolerable and wholesome. Unfortunately the interests involved are complicated and extensive, so that progress has been made only in the slowest fashion. There is a good prospect, however, that in the year 1904 the underground bakehouse, greatest scandal of all, will be brought under the heel of repressive legislation; but much will depend on the attitude of the local authorities throughout the kingdom. So long ago as 1822 the Legislature passed an Act prohibiting the baking and delivery of bread on Sundays. At the present day, eighty years later, that law is openly defied. The London Master Bakers' Society, it is true, in conjunction with the Amalgamated Union of Operative Bakers, have taken upon themselves the task of initiating proceedings, and have spent £1,000 for that purpose. There are many obstacles in the way of securing convictions. It is to be hoped that Parliament may be induced to turn their attention to this matter, so as to ensure the enforcement of a salutary law whereby a large section of the industrial community is granted one day of rest in each week.

Concerning Asafœtida.

Asafœtida is collected in Persia in the districts of Ispahan, Mahior and Abedeh, and Golak, a Russian author, states that domestic animals which have eaten the leaves of the umbelliferous plant which furnishes the resin are thereby impregnated to such an extent that their flesh and milk, and the butter made from the latter, acquire thereby such a nauseating taste and odour as to render them impossible articles of food, though the natives appear to have cultivated a taste for this too pronounced flavour. We commend this observation to the notice of missionaries and travellers in lands inhabited by people of cannibal propensities in the hope that they may find in asafœtida a means of rendering their flesh inedible. The only drawback to this prophylactic measure is that the disgusting qualities of their flesh would only become apparent at a stage of the proceedings when the explorers themselves have long since ceased to take any personal interest in the composition of the *menu*. Still, if anything can be done by other than moral suasion to dissuade savages from the consumption of "long pig," a further step will have been accomplished in the direction of civilisation.

Royal Orthopædic Hospital.

IN our issue of April 19th we remarked that the proposed sale of the site of this hospital seemed "an unbusiness-like proceeding most disadvantageous to the hospital," and recent occurrences have demonstrated the correctness of our view. For instance, a sale on the same side of Oxford Street of a freehold having only one frontage one-seventh the area of this hospital's site realised £10 a square foot. At this figure the value of the Hospital site, which has two frontages, is some £7,000, but if only £7 a square foot can be obtained, then the present value is £49,000, and as a matter of fact, experts who have proved correct hitherto, estimate it as being now worth £47,000. Yet this is the site that the management of the hospital propose to sell for £40,000. As the so-called reasons for sale stated at the annual meeting, such as large average cost of repairs, insanitation, unsuitable, and unhealthy site, &c., have all broken down on examination, it can no longer be claimed that there is the slightest urgency or necessity for sale or letting. It would certainly be wise to rebuild the Oxford Street part in order to earn an increased income of £600 a year, and to accommodate the matron, nursing staff, &c., and set free more beds in the Hanover Square part, which is now the in-patient department of the hospital. A solid offer from a highly responsible firm has been made which will enable the hospital to be rebuilt in whole or part free of cost, and as the governors know nothing of the important conditions which have arisen since the annual meeting, most certainly the whole facts should be put plainly to them before sale is permitted. Their property is being dealt with, and we cannot believe they, the trustees or the committee, could possibly consent to an unnecessary sale, and thus prevent the hospital earning the additional income which it so sadly needs. By rebuilding on present site the property will be immensely improved in value. It has risen £12,000 in three years, and must considerably increase in the future; why, therefore, should these great advantages be thrown away? We have no hesitation in repeating that in our judgment the proposed sale is in every way most disadvantageous to the hospital, and should be opposed by all friends of the hospital. The matter is at present under the consideration of the Charity Commissioners, who are holding a Court of Inquiry into the proposed sale. In any case, the fullest publicity is demanded in the interests of the wise management of the medical charities of the metropolis.

Medical Examination in Cases of Rape.

THE investigation of alleged cases of rape is among the most difficult and responsible with which the medico-legalist has to deal. Dr. Arthur Powell, the police-surgeon of Bombay, in a recent paper on this subject in the *Indian Medical Gazette* for June, offers many practical suggestions. He shows that an important point not mentioned in the text-books refers to the presence of smegma. If the glans be covered with a uniform layer of smegma the possibility of recent complete penetration is negatived. He also insists that too much weight is usually given to the presence of semen on the clothes or person of the accused. The police should have instructions never to allow one accused of a sexual offence to wash his person or retire to a water-closet on any pretext before the surgeon has made his examination. Dr. Powell also shows that unfortunately in India, as in Europe, the superstition prevails that intercourse with a virgin is a certain cure for venereal disease.

The Educational Treatment of Locomotor Ataxy.

ONE of the chief clinical features of ataxia being muscular inco-ordination, attempts have been made to remedy this defect of innervation by a method of re-educating the nerve centres concerned in locomotion. The results have been encouraging, but as success has not been uniform there remains the suspicion of possible errors in diagnosis. Some cases of multiple neuritis often closely simulate ataxia and in such cases graduated methodical exercises might be expected to prove of benefit, whereas in ataxia it is difficult to furnish any plausible explanation of the improvement. In any event, by assisting in the maintenance of the nutrition of the muscular, and perhaps of the nervous, system, such exercises, if proportioned to the strength of the patient, are calculated to delay the further progress of the disease.

American Medical Etiquette.

INTERESTING light is thrown on the view of the modern American medical man regarding certain matters of medical etiquette by a study of the recent issue of the *New York Medical Journal*, one of the leading Transatlantic professional papers, in which the illness of King Edward is considered. Portraits are given of several of the medical men in attendance, with various interesting personal details. Moreover, well-known members of the profession express their views freely concerning various phases of the malady which has so seriously threatened our King's life, and which has turned our Coronation rejoicing into the silence of tragedy. This publicity may be all very well for our American cousins, but we venture to think that the English public would be slow to approve any departure from that reserve and self-suppression which medical etiquette imposes on members of the profession in this country.

Sunstroke and Military Reviews.

MILITARY reviews, as now held during the summer months, are always cause for much discomfort to many of those who have to participate in them, and not infrequently many cases of sunstroke and serious cardiac syncope occur. Drs. Cornil and Chantemesse have recently advocated the holding of summer reviews in the early part of the morning, before eight o'clock. Certainly during the heat of midday the conduct of military reviews is often fraught with danger. Perhaps the War Office will some day find time and wisdom to consider this matter.

Lockjaw and Superstition.

IN a death from tetanus, investigated last week by the Norwich Coroner, a curious superstition came to light. The deceased, who was wearing a carpet slipper at the time, stepped upon a nail, which ran into her foot, and tetanus ensued. At the time of the accident deceased herself pulled the nail, which was a new one, out of her foot. No treatment was adopted, but she instructed her daughter to grease the nail, with a view of causing the wound to heal. Tetanus developed and the patient was removed to hospital, but at too late a stage to given any chance of recovery under the administration of modern scientific remedies. It seems almost incredible that such a survival of mediæval superstition could be found in these days of board schools. The incident affords a timely illustration of the need of the spreading of a comprehensive net in Mr. Balfour's new Education Acts.

A Shoreditch Herbalist.

A CERTAIN Mr. Perdue, of Galt Street, Limehouse, has come into prominence on no less than thirteen occasions in consequence of his having medically attended persons suffering from diseases which subsequently proved fatal. He describes himself as a registered herbalist, and the jury at an inquest last week ingenuously requested the Coroner to call the attention of the General Medical Council to this herbalist's conduct. As the Council is hardly likely to move in the matter, we beg to call the attention of the Medical Defence Union and the London and Counties Medical Protection Society to the case, in the hope that something may be done to prevent any further frauds of the kind on the sick poor.

The Americanisation of our Drinking Habits.

BROTHER JONATHAN and his influence seem to be touching us at all points. We are recognising his power at sea as well as on land, underground as well as "on the surface"; he furnishes us with much of our food, and now, as is evidenced by almost every place of refreshment in the Metropolis, he is revolutionising our "drinks." And there is much in the American invasion of summer beverages for which we may well be thankful. Of the simpler and cheaper kind there is little to disapprove. Many are pleasant and physiologically suitable. The American has proved that "temperance drinks" may be made wholesome and inviting, but, unfortunately, he has not forgotten to show how they may be "fortified" by the addition of gin, absinthe, and other dangerous ingredients.

PERSONAL.

SIR A. CONAN DOYLE, M.D., has been appointed Deputy-Lieutenant of the County of Surrey.

DR. E. FARQUHAR BUZZARD has been appointed Pathologist to the National Hospital for the Paralysed and Epileptic, Queen's Square.

SIR HENRY NORBURY has drawn attention to the lack of suitable accommodation for dealing with wounded on modern warships in time of war.

SIR W. B. RICHMOND has accepted the Presidency of the Betterment of London Association, which seeks to improve the condition of the Metropolis.

DR. E. D. BOND died at the London Fever Hospital, Islington, at the early age of twenty-eight, from scarlet fever contracted in the course of his duties.

MR. CHARLES STEWART, Mr. William McAdam Eccles, and Mr. Arthur Keith have been appointed Hunterian Professors to the Royal College of Surgeons of England.

MR. ALEXANDER G. R. FOULERTON, Director of the Cancer Research Laboratories at the Middlesex Hospital, has been appointed a member of the German Cancer Investigation Committee.

WE trust Lord Wandsworth's example will have many imitators. He has sent to King Edward's Hospital Fund for London a gift of £500 as a thank-offering for his Majesty's recovery.

PROFESSOR ERB will deliver the opening lecture of the Winter Session of the Post-Graduate College of the West London Hospital on October 8th, the subject being "Syphilis of the Spinal Cord."

MR. H. B. WHITEHOUSE, of Birmingham, a student at St. Thomas's, not only gained the Entrance Science Scholarship, valued at £150, with a Certificate of Honour, but was also successful in carrying off the William Tite Scholarship, worth £27.

PROFESSOR VIRCHOW for some time past has been staying at Schierke, in the Harz mountains, recovering from the effects of his severe accident. He has been lately subject to fainting fits, and fears are entertained that at his advanced age he may not recover.

DR. W. G. GRACE, the "Grand Old Man" of the cricketing world, celebrated his fifty-fourth birthday on Friday, July 18th. We heartily wish him "many happy returns of the day." Dr. Grace has doubtless found greater pleasure in wielding the bat than handling the knife.

SURGEON-MAJOR FORD, who recently died at a ripe old age at Torquay, is said to have shot more big game than any man living. His shooting book contains the record of the deaths of 122 tigers, thirty-five panthers, seven Indian lions, besides many bison, bulls, and deer.

WE understand that Lord Salisbury has expressed the intention of spending most of his time in comparative retirement at Hatfield. It is well to remember that our veteran late premier is not only a politician but an eminent scientist, and especially an enthusiastic chemist; and we trust that from the quiet laboratory at Hatfield world-moulding power may still flow.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

MEDICAL ETIQUETTE AND THE PUBLIC.—The burning fatality at Whitehead, by which a young woman lost her life, and the subsequent inquest, have supplied a text to many of the daily papers for articles on medical etiquette, which generally suggest that the ethical rules of our profession are at variance with the common laws of humanity. On June 26th Miss Allen joined an excursion from Belfast to Whitehead, and on the railway platform at the latter place her light dress caught fire from a burning wax vesta carelessly thrown away by a smoker. Dr. Calwell, of Duncairn Gardens, Belfast (not Dr. Wm. Calwell, one of the physicians to the Royal Victoria Hospital, as has been erroneously reported), was on the platform, and came to the aid of the unfortunate girl, taking her on a car to an hotel near to the station. On the way they met Dr. Martin, the local practitioner, who alleges that he offered to help and received a snubbing reply, being told that the girl was hysterical and not much hurt, so that when a messenger was sent to him subsequently asking for a supply of carron oil he refused. Dr. Calwell denies that he refused Dr. Martin's offers of help, or made light of the girl's injuries, and when, after several weeks, she died, the coroner's jury elected to prefer his version of the facts, and condemned Dr. Martin's action. It is a painful and humiliating episode for the profession, the members of which in Belfast seem to divide the blame equally between the two young men, thinking the one too high-handed and the other too ready to take offence.

NORTH OF IRELAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.—The annual meeting of this branch was held in the Museum, Belfast, on the 17th inst., the President, Dr. J. Singleton Darling (Lurgan), in the chair. Cases were shown and discussed by Dr. Cecil Shaw, Professor Lorrian Smith, Professor Byers, Mr. Kirke, Dr. Mitchell, Dr. Norman Barnett, Dr. Dempsey, and Dr. Calwell.

Sir William Whitla announced that in future the branch would be invited to hold its meetings in the new medical institute, which will, he hopes, be ready in October.

The President announced the result of the election of office-bearers for the coming year as follows:—President: Prof. Sinclair, F.R.C.S. Vice-Presidents: (Town) Dr. A. B. Mitchell; (Country) D. Donnan, Holywood. Council: (Town) Sir William Whitla, Dr. Dempsey, Dr. Cecil Shaw, Professor Lindsay, Dr. J. Campbell, Dr, McKisack, Professor Byers, Mr. T. S. Kirk. (Country) Dr. J. C. Martin, Portrush; Dr. St. George, Lisburn; Dr. Stuart, Ballymena; Dr. Gaussen, Dunmarry; Dr. Darling, Lurgan; Dr. Hall, Monaghan; Dr. Agnew, Lurgan; Dr. Gray, Armagh. Representatives of Branch on Council: Professor Byers, Dr. Calwell. Representatives on Parliamentary Bills Committee: Dr. Dempsey. Hon. Treasurer: Dr. George Gray, Newcastle, County Down. Hon. Secretary: Dr. Calwell, 1. College Square North, Belfast.

Literature.

LOCAL TREATMENT IN DISEASES OF THE AIR PASSAGES. (*a*)

THIS little book is a reprint of two lectures delivered at the Medical Graduates College and Polyclinic, and published in the first place in the *British Medical Journal* in November last. On their first appearance these lectures caused considerable emotion in rhinological circles, and led to a controversy which was carried on with rather more bitterness than we like to see displayed in medical polemics. There can be no denying, however, the fact that the author's timely protest against the "lust of operation" was of great service in drawing attention to a state of things which was rapidly bringing discredit on the specialty.

The first lecture treats of affections of the upper air passages of a purely local character. The question of adenoid vegetations naturally takes up a considerable space, and the author, in describing his method of removing them, lets drop some useful hints. A critical examination is made of Mr. Arbuthnot Lane's treatment by means of "breathing exercises." Both here and in the subsequent dispute with Mr. Lane the author gets the best of the argument. But whether it was quite fair to class "breathing exercises" with Christian Science and rheumatism rings is another question. Breathing exercises, if properly carried out after the removal of the growths, are undoubtedly of use in preventing recurrence. In the second lecture local manifestations of general systemic diseases are dealt with. Particular stress is laid on the importance of thoroughness in the treatment of laryngeal tuberculosis, the half-hearted way in which it is done often doing more harm than good. The author gives at some length his views on the possibility of curing asthma and other reflex disorders by nasal operation. He says that he has never seen a case of a so-called reflex neurosis disappear after removal of adenoids, and, except in a small percentage of cases, after any intranasal operation. This experience is not in accordance with that of most rhinologists.

The author reprints in the form of an appendix two letters he sent to the *British Medical Journal*, defending the position he had taken up.

On the whole this is a very instructive and suggestive little book, but it would have been better if it had been freer from personalities.

TRANSACTIONS OF THE ROYAL ACADEMY OF MEDICINE. (*b*)

THIS, the nineteenth volume of the "Transactions of the Royal Academy of Medicine in Ireland," contains a number of interesting papers in each section. In Medicine, Dr. W. R. Dawson contributes a valuable record of a year's work at Farnham Asylum. In Surgery, Mr. H. Newman's paper, "Double Primary Chronic Glaucoma," is a contribution of perennial value. The Rotunda Hospital report gives value to the Obstetrical section, and in State Medicine, Dr. M'Weeney made a valuable addition to our knowledge by his paper on Tuberculosis.

Mortality of Foreign Cities.

THE death-rates in the principal foreign cities of the world from which official returns are received by the Registrar-General, were for the last week per 1,000 living: In Calcutta 29, Bombay 36, Madras 35, Paris 18, Brussels 13, Antwerp 16, Amsterdam 17, Copenhagen 15, Stockholm 12, Christiania 14, St. Petersburg 24, Moscow 31, Hamburg 15, Munich 22, Vienna 19, Prague 23, Buda-Pesth 16, Trieste 22, Rome 20, Venice 13, Cairo 40, Alexandria 33, New York 18, Philadelphia 17, Boston 16.

(*a*) 'Some Thoughts on the Principles of Local Treatment in Diseases of the Upper Air Passages." By Sir Felix Semon, M.D., F.R.C.P. Macmillan and Co. 1902. Price 2s. 6d.

(*b*) "Transactions of the Royal Academy of Medicine in Ireland." Vol. xix. Edited by John B. Story, M.B., F.R.C.S. Dublin: Fannin and Co., Limited. London: Baillière, Tindall and Cox. 1901.

Obituary.

DR. WILLIAM WARWICK, OF BELFAST.

By the death of Dr. William Warwick, Belfast has lost one of its oldest and most respected medical practitioners. He was one of the earliest students of the Belfast Queen's College, but, following the practice of the time, he went for the M.R.C.S.Eng., and to Aberdeen for his M.D. He was one of the old school of family physicians—the friend quite as much as the physician. Of his latter-day clients he had known most of them from their birth, and had become endeared to them by unnumbered acts of kindness. Of a particularly modest and retiring disposition, he declined many honours that his fellow citizens would have conferred on him, and chose the quiet routine of a family practice, in the duties of which he won love and respect, and died honoured.

DR. HEMPHILL, OF CLONMEL.

It is with regret that we announce the death of Dr. W. D. Hemphill, of Clonmel, which event took place on Sunday, July 6th, at his residence, Oakville. During the past two years failing strength prevented his carrying on his practice with his usual vigour, and within the past five months the natural effects of advancing years became more marked. He was born in 1816, and educated at the Endowed School, Clonmel. He took the L.R.C.S.I. as far back as 1838, and the Fellowship of the College in the year of the institution of the qualification. In the same year he became an M.D. of St. Andrew's University. He had a large and remunerative practice in Clonmel and its neighbourhood, which left little time for literary work, yet he managed to find time for writing an historical sketch of the abbeys, castles, and country around Clonmel. In 1875 he published a valuable paper on blood stains in their medicolegal aspect. Until quite recently he was consulting physician to the gaol, and he was one of the last of the consulting physicians to the district lunatic asylum.

Medical News.

Health of the City of London.

The City of London must be considered almost unique as regards its conditions of life and death, opportunities for work and pleasure, states of labour and repose. Dr. Collingridge, in his recently-issued report, shows that the birth-rate is only 13·7 per thousand, while in England and Wales it was 28·9. The city mortality works out at 16·6 per thousand as compared with 18·6 for the thirty-three great towns. The infantile death-rate of children under one year of age was 160 per 1,000 births. Deaths from accidents or violence amounted to 7·45 per cent. Certainly London must be considered as a study to itself.

Royal College of Physicians, Ireland.

The King's Professorship of Materia Medica and Pharmacy will become vacant in October, when the President and Fellows of the College will proceed to elect a Professor to the chair. Candidates for the appointment must send in their names, the places of their education, the University at which they have taken their Medical degrees (if any), and the places at which they have practised, on or before October 10th, 1902, to James Craig, B.A., M.D., Univ. Dub., Fellow and Registrar of the Royal College of Physicians of Ireland; and to the Rev. J. P. Mahaffy, D.D., Registrar of Trinity College, Dublin.

A Memento of Sir William Jenner.

Lady Jenner has presented the Royal College of Physicians of London with an interesting memento of the late Sir William Jenner in the shape of a handsome silver vase given to that distinguished physician by the Duke of Albany.

The Cost of the Small-pox Epidemic..

The imposition of a rate estimated at close upon 3½d. in the pound will open the eyes of the public to the fact that an epidemic of small-pox is a very expensive luxury, and incidentally to the discovery that revaccination, whatever its cost, affords an economical means of avoiding this enormous expenditure. By easy steps they will come to understand that persons who from ignorance, indifference or prejudice fail to avail themselves of this protection are doing so at the cost of the community. Moreover, the gross expenditure of the Metropolitan Asylums Board in respect of small-pox during the last six months, over half a million, by no means represents anything like the total cost of the epidemic, for we must take into account the misery inflicted on innocent victims indirectly affected thereby, the loss of labour value, and the cost of disinfection, inspection, &c. In round figures, we may take it that the present epidemic has already cost upwards of two millions sterling, and will entail the expenditure of several millions more before it subsides. This is a valuable object lesson, which should open the eyes of the public to the foolishness of permitting such an onerous and unnecessary tax to be thrown upon the public.

Small-pox and Fever in London.

At midnight on Friday there were 469 patients under treatment in the small-pox institutions of the Metropolitan Asylums Board. Two additional cases were admitted on Saturday—one each from Wandsworth and Fulham, and on Sunday, down to 7 p.m., one further case had been notified which came from Paddington. The fever and diphtheria patients under treatment in the Board's fever hospitals at midnight on Friday numbered 3,557.

Dinner to Colonel Hodson, R.A.M.C.

At the Dolphin Hotel, Dublin, on Thursday, the officers of the Royal Army Medical Corps in Dublin and the Civil Surgeons attached gave a complimentary dinner to Lieutenant-Colonel R. D. Hodson, R.A.M.C., acting Principal Medical Officer of the 3rd Army Corps, who is about to leave for Ceylon. Lieutenant-Colonel F. G. Adye Curran, R.A.M.C., occupied the chair, and Lieutenant-Colonel W. P. Inman, R.A.M.C., the vice chair, and all the R.A.M.C. officers and civil surgeons stationed in Dublin were present.

Starving a Recalcitrant Jury.

A coroner's jury at Sutton Coldfield has, we learn, been locked up without food or water for fourteen hours because they were unable to agree on their verdict. A coroner is armed with immense power, and doubtless rightly so, but when he uses it for the perpetuation of methods of barbarism it is necessary that the sufferers should be protected. The Coroners' Society, and many members of the medical profession, have long been agitating for reform in our Coroners' Courts, and such instances as we have referred to may well further their efforts.

Royal Dental Hospital of London.

The annual *conversazione* and prize distribution took place on Friday last at Prince's Hall, when a large number of the students and friends assembled. The Dean (Mr. Morton Smale), who presided, said the King, who became Patron of the Hospital last year, had now commanded it to be called Royal. This being the first public gathering since that event, it seemed to him to be appropriate to send to the King a message of congratulation on his convalescence and of thanks for the honour conferred upon the charity. The message he proposed to send was as follows:—"The staff and students of the Royal Dental Hospital of London, assembled at their annual prize distribution, desire to express their loyalty to the King and to the Throne, their sincere and heartfelt thankfulness for his Majesty's convalescence, and their gratitude for the honour recently conferred upon the institution by its having been created a Royal Hospital. Both staff and students will always endeavour to uphold the honour thus conferred upon it." Sir A. Rücker, having distributed the prizes to the successful students, delivered a brief address, in which he expressed the hope that the time was coming when, more than in the present, the different schools in London would feel proud to be part of the great University of London. If success was attained, as he believed it would be, the London University would be one of the most marvellous institutions in the world. The University was introducing a new matriculation examination, in which it was not intended to overweigh the student, but to leave spare time for individual improvement. In conclusion, Sir Arthur said the University was also considering the possibility of founding a large medical institute for preliminary medical studies.

German Spa Excursion.

INFORMATION concerning the proposed medical excursion to German watering-places and health resorts may be obtained from Dr. W. H. Gilbert, Baden-Baden, and Dr. P. Meissner, 81 Kurfürstenstrasse, Berlin. The amount of the subscription is 150 marks (£7 10s.).

Munificent Bequest by a Medical Man.

A SUM of £20,000 was left by Mr. G. G. Scale, surgeon to the Portsmouth Corporation, to provide annuities of £30 each for eighteen deserving blind persons of either sex, born in Hampshire, or who had lived in that county for five years prior to becoming candidates.

Vital Statistics.

THE deaths registered last week in seventy-six great towns of England and Wales corresponded to an annual rate of 14·5 per 1,000 of their aggregate population, which is estimated at 14,862,456 persons in the middle of this year. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—from measles: 1·2 in Bristol, 1·4 in Birkenhead, 1·7 in Bootle, 1·8 in Rhondda, 1·9 in Rochdale, 2·4 in Plymouth and in Warrington, and 2·7 in Barrow-in-Furness; from scarlet fever: 1·6 in Burnley, 2·0 in Stockton-on-Tees, and 3·2 in West Bromwich; from diphtheria: 1·2 in Walsall, 1·5 in Coventry, and 1·6 in West Hartlepool; from whooping-cough: 1·3 in West Ham and in Aston Manor, 1·4 in Birkenhead, 1·5 in South Shields, 1·7 in Bootle, 1·8 in Barrow-in-Furness, and 2·3 in Norwich; from "fever": 1·5 in Ipswich, and 1·8 in Barrow-in-Furness; and from diarrhœa: 1·4 in Preston, and 2·6 in Bootle. The 18 deaths from small-pox included 13 belonging to London, 2 to Swansea, and 1 each to Croydon, Tottenham, and Walthamstow. In London 2,530 births and 1,280 deaths were registered. Allowing for increase of population, the births were 78, and the deaths 254, below the average numbers in the corresponding weeks of the last ten years.

Society of Medical Phonographers.

THIS Society will hold its next annual Shorthand Examination early in May, 1903. Two prizes will be offered, each of the value of £5, one for first-year students and one for students of more than one year's standing. The competition will be open to any registered medical student in the United Kingdom who has not taken a first prize at one of the Society's previous examinations. It will be held simultaneously in London, Edinburgh, Dublin, and at any provincial medical centre in the United Kingdom at which not fewer than three candidates shall offer themselves. Intending candidates should send in their names as early as possible to Dr. P. G. Griffith, Bonhams, Farnborough, Hants, who will furnish them in return with a detailed prospectus of the examination. The latest date for receiving entries will be April 15th, 1903.

St. Bartholomew's Hospital and College.

THE following scholarships, medals, and prizes were awarded last week for the Winter and Summer Sessions, 1901-1902:—Lawrence Scholarship and Gold Medal.—R. C. Elmslie. Brackenbury Medical Scholarship.—A. E. Thomas, Prox. Acc., W. W. Jendwine, E. G. Pringle. Brackenbury Surgical Scholarship.—F. P. Connor. Matthews Duncan Medal and Prize.—A. R. Neligan. Senior Scholarship in Anatomy, Physiology, and Chemistry.—J. G. Atkinson. Senior Entrance Scholarships in Science.—J. M. Hamill, R. F. Moore. Junior Entrance Scholarships in Science.—H. E. Quick. Preliminary Scientific Exhibition.—D. W. Hume and A. M. Jukes. Jeaffreson Exhibition.—A. Kernahan and E. de Verteuil. Shuter Scholarship.—J. K. Willis. Kirkes Scholarship and Gold Medal.—E. G. Pringle. Hichens Prize.—K. S. Wise. Harvey Prize.—F. B. Ambler. Sir George Burrows' Prize.—E. G. Pringle. Skynner Prize.—E. G. Pringle. Practical Anatomy (Junior).—Treasurer's Prize.—P. L. Giuseppi. Practical Anatomy (Senior).—Foster Prize.—F. B. Ambler; C. B. D. Butcher (Lecturer's Prize). Junior Scholarships in Anatomy and Biology (1902).—1, P. L. Giuseppi; 2, H. E. Quick. Junior Scholarships in Chemistry and Histology (1901).—1, F. B. Ambler; 2 R. H. Bott.

Charing Cross Hospital Medical School.

THE following scholarships, medals, and prizes for the Summer Session, 1901, and Winter Session, 1901-1902, have been awarded:—Epsom Scholar.—Mr. E. H. Hugo. Huxley Scholar.—Mr. W. K. Beaman. Llewellyn Prize, Certificate and £25.—Mr. S. A. Boyd. Pereira Prize, Certificate and £5.—Mr. H. M. Joseph, Mr. C. L. Lakin (equal). Golding Prize, Certificate and £10.—Mr. L. E. M. Smith. Governors' Clinical Gold Medal.—Mr. A. G. Payne. Huxley Medal with prize of £10.—Mr. A. A. Smith. Anatomy (Senior).—Prize, Mr. A. Dinnis. Anatomy (Junior).—Prize (Steadman), Mr. L. E. M. Smith; Prize (School), Mr. F. G. Edholm. Biology.—Prize, Mr. W. K. Beaman. Chemistry.—Prize, Mr. W. K. Beaman. Physiology (Senior).—Prize, Mr. A. A. Smith. Physiology (Junior).—Prize, Mr. L. E. M. Smith.

Pass Lists.

Conjoint Examinations in Ireland by the Royal College of Physicians and Royal College of Surgeons.

THE following candidates have passed the First Professional Examination:—

Honours (Order of Merit).—P. Foran, M. O'Connor, C. W. Greene, W. P. Kelly, H. J. Perry, equal; H. M. Harrison, G. Petch, equal; E. H. F. Gilligan, J. B. Kelly, equal; C. M. Burton, J. R. Tobin, equal

Passed all subjects (alphabetically).—T. A. Burke, M. Cohen, Miss K. Dillon, J. Gaffney, W. Glennon, M. P. Healy, A. Hogan, J. Humphreys, M. J. Kelly, J. J. P. Kinsella, T. H. Massey, W. St. L. Moorhead, C. F. Murphy, D. M'Cormack, R. O'Kelly, O'C. J. O'Reilly, P. J. O'Reilly, J. Prindiville, R. J. Smallman, C. H. Waddell, M. Walters, R. Welply.

Completed Examinations: J. Burke, S. Clarke, J. J. Corr, Miss M. K. H. Griffin, F. N. Hillis, C. A. Lerper, A. L. Mansfield, J. O'L. Murray, S. M'Causland, F. J. M'Manus, J. V. O'Hagan, J. V. Sage, R. J. Swanton, G. W. Wright.

Society of Apothecaries of London.

AFTER the usual examinations the L.S.A. diploma has been granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. C. Curtis, H. G. Daft, S. F. Hickman, G. W. C. Hollist, E. A. Houchin, T. G. Miles, O. Millauro, G. Roper, T. Scatchard, J. E. Skey, H. H. Sloane, and H. C. S. Woodward.

Pharmaceutical Society of Ireland.

PRELIMINARY EXAMINATION.

The following candidates have passed:—

H. D. Starkey, D. Walshe, W. H. Ashmore, J. O. Lane, T. E. Yarr, C. E. Taylor (W. Kirkwood, R. Mulligan, M. C. Neill), D. Donnelly (J. Bell, W. W. Bennett), J. J. O'Toole, J. M. McConnell, S. P. Moloney, D. J. Nugent, Emily Warren, J. W. McKay, P. Cagney, passed. Fifteen candidates were rejected.

PHARMACEUTICAL LICENCE EXAMINATION.

W. A. Berry, J. B. Doran, R. Telford, (A. J. Thompson, J. J. Conway), T. Barry, J. Taylor, J. A. Walsh, Rose T. O'Connor, passed. Fifteen candidates were rejected.

REGISTERED DRUGGIST EXAMINATION.

H. Johnston, T. J. May, G. Richardson, passed. One candidate was rejected.

PHARMACEUTICAL ASSISTANT EXAMINATION.

J. H. Davis, A. O. Wells, passed. One candidate was rejected.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

P. B.—We are unable to comply with your request in the absence of the gentleman who furnished the report. We shall be pleased to place you in communication with him on his return.

Mr. Raber.—We do not admit contributions from other than medical men, and we are not disposed, after perusal of your manuscript, to make an exception in your favour.

Mr. Beck—We hope to complete the analysis shortly, and this will place us in a position to reply to your inquiry.

Traveller.—We know of no portable filter which would quite answer your purpose. The safer course when abroad is to avoid the "town water" altogether, all beverages being diluted with one or other of the mineral waters, which can be had at every hotel and restaurant.

THE SURGERY OF HOMŒOPATHY.

At the recent British Homœopathic Congress the President dwelt on the important developments of surgery, and practically admitted that in the realm of practical surgery "homœopathic methods" could hardly be followed.

Adenoids.—Most surgeons prefer operating under nitrous oxide, or nitrous oxide and ether, with the patient in the sitting-up position. On the other hand, a few specialists invariably use chloroform. To those skilled in operating under that particular anæsthetic the proceeding is not without its advantages.

F. R. (Surbiton).—The symptom you describe is most probably due to gall-stones. It is only in extreme cases that the advisability of operation need be seriously discussed. The great majority of cases get relief under simple medical treatment. Moreover, the symptoms of gall-stone sometimes recur even after removal of the gall-bladder.

Quærens.—1. You had better irrigate with a solution of boracic acid, which in that particular case is the most suitable of all antiseptics. Conjunctivitis due to "motoring" will, as a rule, quickly mend itself if the patient keeps quiet. 2. Rest is essential, and without its rigid enforcement treatment by drugs will be useless. 3. Strawberries do no harm in gout, and are popularly credited with a beneficial action in that condition.

Appointments.

Chaldecott, John Henry, L.R.C.P.Lond., F.F.P.S Glasg., Honorary Anæsthetist to the Italian Hospital, Queen's Square, W.C.

Clayton, T. M., M.B., B.S.Durh., Medical Officer of Health to the Gateshead Town Council.

Coates, W. H., M.B.Durh., Public Analyst to the Withernsea Urban Council.

Grindrod, J. A., M.R.C.S.Eng., Medical Officer of Health to the Horden Urban District Council.

Murray, J. G., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Scarborough District.

Pridmore, John Walter, M.R.C.S., L.R.C.P.Lond., District Medical Officer and Public Vaccinator of the Ryde District of the Isle of Wight Union.

Slader, George Burgess, L.R.C.S. and L,M. Irel., L.S.A.Lond., Medical Officer of Health to the Gainsborough Rural District Council and Medical Superintendent of the Rural District Council's Isolation Hospital, Gainsborough.

Toye, C. J., M.D.Lond., Medical Officer of Health for the Northam (Devon) District Council.

Vacancies.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Applications to the Secretary.

County Asylum, Mickleover, Derby. Junior Assistant Medical Officer (male). Salary £120, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Halifax Union Poor-law Hospital.—Resident Medical Officer. Salary £130 per annum, with apartments, rations, and washing. Applications to Arthur T. Longbotham, Solicitor and Clerk to the Guardians, 4, Carlton Street, Halifax.

Haydock Lodge Asylum, Lancashire.—Assistant Medical Officer. Salary to commence at £175 a year, with furnished quarters, board, washing, &c. Applications to Dr. Street, Haydock Lodge, Newton-le-Willows, Lancs.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance. Applications to Dr. W. D. Moore, Medical Superintendent.

North Cambs. Hospital, Wisbech.—Resident Medical Officer. Salary £150 per annum, with furnished house. Applications to F. J. Gardiner, Hon. Sec.

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Also one Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel are found. Applications to M. I. Preston, Journal Chambers, Nottingham.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum Applications to the Secretary, E. S. Baylis, 19, Moorgate Street, Rotherham.:

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance and washing. Applications to the Secretary.

Births.

Boobbyer.—On July 17th, at 55, Burn's Street, Nottingham, the wife of Philip Boobbyer, M.B., of a daughter.

Cameron.—On July 15th, at West Park House, Dewsbury, the wife of G. Clark Camaron, M.D., of a daughter.

Fuller.—On July 19th, at 7, Oxford Row, Bath, the wife of A. Leonard Fuller, M.R C S Eng., L.R.C.P.Lond., of a son.

Gubbins.—On July 16th, at 15, Kildare Terrace, Bayswater, W., the wife of Colonel W. L. Gubbins, M.B., Royal Army Medical Corps, of a son.

Thompson.—On July 13th, the wife of F. B. Thompson, M.R.C.S., L.R.C.P.Lond., of a son.

Marriages.

Hawthorn—Metcalfe.—On Wednesday, July 16th, at St. Matthew's Church, Leyburn, the Rev. John Hawthorn, M.A.Camb., of Leyburn, to Mary (May), second daughter of Richard Metcalfe, M.D., of Eastfield Lodge, Leyburn.

Mayo—Smith.—On July 17th, at St. Thomas's Church, Portman Square, London, Thomas Alfred Mayo, M.B., of Cowes, I. of W., third son of Alfred Charles Mayo, J.P., of Great Yarmouth, to Mildred, youngest daughter of Sir Thomas Smith, Bart., K.C.V.O., F.R.C S., Serg.-Surgeon to H.M. the King.

Deaths.

Auchinleck.—On July 12th, at the Hotel Métropole, London, Surgeon-General Grahame Auchinleck, M.D., R.A.M.S., aged 76 years.

Watt.—On July 3rd, 1902, at his residence, Oaklands, Niagara-on-the-Lake, Ontario, Canada, West, in his 80th year, E. Halliday Watt, M.R.C.S.Eng., L S.A., formerly of Deal, Kent.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m.—Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. A CASE OF
INTERNAL HYDROCEPHALUS
IN THE
ADULT, SIMULATING CEREBRAL TUMOUR.

By **WM. B. WARRINGTON, M.D. LOND., M.R.C.P.,**
Physician to the David Lewis Northern Hospital, Liverpool; Pathologist to the Stanley Hospital.

VARIOUS morbid conditions give rise to symptoms which resemble those of cerebral tumour; sometimes these depend on a constitutional cause, sometimes they are due to nervous disorders of an altogether different category. When the diagnosis tumour cerebri is made, treatment in spite of increased physiological knowledge and improved surgical technique is very unsatisfactory, though operative interference is often indicated, even if there is no prospect of removing the growth.

In the case to be recorded a cerebral tumour was wrongly diagnosed, and the condition revealed at the autopsy was perhaps remediable. It has been appropriately said that while it was easy to be wise after the event our endeavour should be to be wiser. This thought caused me to think over the case, and now to record it.

The patient, a shipping clerk, æt. 39, in a good position, was sent to me by Dr. McDougall. He was a married man with five healthy children. Strictly temperate, and no evidence or suggestion of syphilis. For some months he had been troubled with frontal headache, though not very severe, and occasionally had had attacks of vomiting without apparent cause. He mentioned also that his memory had been failing, and alluded to his inability to check his accounts; indeed, at the time I first saw him this mental failure was the chief symptom, the headache and vomiting having disappeared.

On examining him I found his speech slow and deliberate, there was slight tremor of the tongue, but not of the lips or hands. His gait was practically normal though the strength impaired. There was no ataxia, no Romberg's sign and the knee-jerks were also natural. The pupils were equal and reacted normally, vision was excellent, the optic discs were, however, slightly blurred.

In order to test his memory and also his handwriting a short passage was dictated. This had to be read almost word for word before he could grasp the sense; the writing was slow and painful, the words were misspelt, the misspelling consisting in a redundancy of the letters. It was evident that there was a great mental deterioration. The diagnosis made was organic brain disease, perhaps tumour, possibly general paralysis. I saw the patient again at his home several times; his condition rapidly became worse, within a month he had sank into comple mental hebetude, and had lost all capacity of appreciating his surroundings; he also passed his excreta in the bed, and was found then to have marked double optic neuritis with hæmorrhages. A little later the mental blankness had passed away and was replaced by delusions. No paralysis could be found, and no disorder of movement in the limbs, though the weakness was profound. He also developed slight but distinct exophthalmos in the left eye. He slightly improved, but towards the end of the second month the mental hebetude again increased, and death occurred suddenly about fourteen weeks after I had first seen him.

During the progress of the case it was thought that the diagnosis of tumour was justified.

No operative interference was suggested first, because there were no localising symptoms; secondly, because the mental state seemed too profoundly affected; and, thirdly, because the patient did not suffer any pain.

Autopsy.—Permission was obtained to examine the brain. The skull and dura mater were normal, the lateral ventricles were found to be very greatly distended with clear fluid. The choroid plexuses were congested and their veins tortuous; the small veins lining the walls of the ventricle were also clearly distended. The ependyma was throughout normal, smooth and glistening.

The foramen of Monro was considerably dilated.

The aqueduct of Sylvius was opened longitudinally, and in its whole course seemed patent. In the floor of the fourth ventricle there was, however, evidence of a pathological process. The normal delicate ependyma was replaced by a rough, raised, lustreless formation, which microscopic examination showed to be inflammatory vascular connective tissue. It could not be definitely ascertained whether this formation had occluded the foramina which are said to be normally present. There was no growth or any other abnormality found within the cranium.

The case, therefore, was one of acquired hydrocephalus in the adult.

The diagnosis of this rare condition is of importance, because it appears that puncture of the ventricle might have at least considerably alleviated the patient.

Internal hydrocephalus appears under several morbid conditions: (1) as part of any meningitis, (2) as the mechanical consequence of tumours, &c., (3) as the ordinary infantile or congenital hydrocephalus, (4) as a result of epidemic cerebro-spinal meningitis.

This case, however, appears to belong to the class studied first and chiefly by Quincke, and called serous meningitis. An excellent description is given by Oppenheim in his "Lehrbuch," and an exhaustive paper has been published by Kupferberg. English authors have also written about the disease, though not very fully. Quite recently, in the Spring number of *Brain*, Parkes Weber describes several cases, and gives an excellent account of the condition.

Are there any points which may lead one to distinguish the case from that of cerebral tumour with which it is usually confounded?

1. *Duration.*—In some cases the illness lasts longer than is usual for tumour, and its progress is characterised by intermissions. Oppenheim mentions a case in which the symptoms continued for eight years.
2. The skull may be enlarged, and this fact suggests the nature of the disease.
3. Absence of localising symptoms, or if the cranial nerves in the anterior fossa are affected by pressure the resulting paralyses are of a fluctuating character.
4. The following symptoms may have value, and were present in my case:—Slight exophthalmos, fine tremors of tongue, hands and lips, weakness, without definite palsy of the legs.
5. Examination of the fluid obtained by lumbar puncture may be important; the recognition of cell elements would suggest a meningeal origin. The significance of albumin is varied. As a rule the figures collected by Weber show that there is not much albumin present; on the other hand, I have known tumour formation to be accompanied by a very considerable amount of albumin in the cerebrospinal fluid.

As to the ætiology practically nothing is known; perhaps, as Weber suggests, it may be compared with serous effusions into the pleura or peritoneum, but for a discussion of this and other theories the reader is referred to that writer's paper (*loc. cit.*). What I wish to emphasise is, that the disease is one which it is perhaps possible to diagnose and to relieve.

ASTHENOPIA. *(a)*

By E. KENNETH CAMPBELL, M.B.Ed.,
F.R.C.S.Eng.,
Surgeon Western Ophthalmic Hospital, &c.

Asthenopia is a convenient term to express that condition of "weak sight" which may exist, visual acuteness being good, either in emmetropia or ametropia *after the proper correction by glasses has been used.* Whilst the ordinary text-books discuss fully the treatment of the various forms of refractive errors, they usually deal quite inadequately, or else too diffusely, with that large group of cases comprised within the term "asthenopia." The following series of articles is intended as an exposition of the subject in its entirety:—

Principles.—When an object is looked at, the two eyes are involuntarily, and simultaneously, directed to it in such a way that its image falls upon each of the two yellow spots, and the straight line extended from the centre of the object looked at to the centre of its image formed on the yellow spot, is known as the *visual axis.*

The adjustment of the two eyes so as to bring the yellow spots into alignment with the object looked at is termed *fixation.*

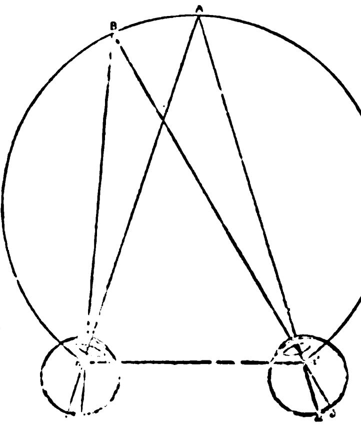
Central, Direct, or Yellow-spot Vision.—All parts of the retinal image outlined upon the yellow spot are exact, sharp, and well-defined.

Ex-central, or Indirect, Vision—An image outlined on the retina at a point away from the yellow spot, is less and less exact and sharp the farther off it lies from the yellow spot, in accordance with the principle that the sensitiveness of the retina decreases progressively from the yellow spot to the periphery.

Identical, or Corresponding Points.

Although two retinal images of an object are formed, yet only *one is seen.* This is due to the fact that for each given point in one retina there is a corresponding point in the other physiologically identical with it, the two mutual points always acting together. If the two eyes move together in perfect unison the two retinal images, falling upon "identical points," are fused into one mental image, and so the object is seen as a single one. The psychological process involved therein constitutes *binocular single vision.*

If, on the other hand, the two eyes do not move together in perfect unison, the images of an object will fall upon non-identical parts of the two retinæ, and so *diplopia*, or double-vision, results.



A, point of fixation the retinal images of which are formed at a; a^1 b b^1 are identical points, ∴ the distance ab = the distance $a^1 b^1$. n, n^1 = the nodal points. The angles a n b, $a^1 n^1 b^1$, = each other and likewise to the opposite angles, A n B, A n^1 B. Also in the triangles B C n, A C n^1, the opposite angles at C are =; ∴ in these triangles the remaining angles at A and B are =. ∴ the point B by which the corresponding images b, b^1 are formed must lie in the arc of a circle passing through the points B, n, and n^1. Similarly, it can be shown that any other point forming corresponding images on the two retinæ will lie in the arc n A n^1.

The image seen by the fixing eye is exact and sharp *and in its right place*, because it falls on the yellow spot: it is termed *the true image.* On the other hand, the image seen by the non-fixing eye is less distinct and sharp than the other, *and is in its wrong place*, because it falls on the retina away from the yellow spot: it is termed the *false image.*

Diplopia is known as *homonymous* when the false image is on the same side as the non-fixing eye, and *heteronymous*, or *crossed*, when it is on the same side as the fixing eye, the false image formed on the non-identical point of the retina of the non-fixing eye *being projected into that position in space from which it has been educated to receive a stimulus.* So that the double images would be homonymous or heteronymous, according as the lines of fixation intersect in front or behind the fixed point.

Stereoscopic Vision (*Gr.* stereos—solid, skopeo—I view).—A judgment of the first two dimensions of space, length and breadth, can be formed by the one eye alone. For stereoscopic vision, or the judgment

---

(*a*) *Gr.* asthenes—weak, ops - sight.

of the third dimension, *i.e.*, the depth and solidity of an object (perspective), the aid of the other eye is necessary (binocular single vision), as the two images on the two retinæ constitute two slightly different pictures, the sum of which = stereoscopic vision.

Varieties of Ordinary Diplopia.

Name.	Image of R E as contrasted with that of L E.	Caused by a pathological deviation.	Caused artificially by a prism held, base.	Corrected by Turning.	Corrected by prism held, base.
Homonymous diplopia	On R side	Either eye inwards	In before either eye	Both eyes outwards	Out before either eye
Heteronymous (or crossed)	On L side	Either eye outwards	Out before either eye	Both eyes inwards	In before either eye
Right diplopia	Below	R E up or L E down	Up before R E or down before L E	R E down and L E up	Down before R E or up before L E
Left diplopia	Above	R E down or L E up	Down before R E or up before L E	R E up and L E down	Up before R E or down before L E

Monocular Vision.—In certain cases of diplopia, usually those which develop in early life, the patient can cultivate the habit of ignoring the false image. When this is so, the condition of sight is that of monocular vision, or vision with a single eye, which implies the negation of stereoscopic vision.

Orientation is the faculty by means of which we are enabled to see objects in their right place. If the two eyes be directed forwards, an object situated to the right of the visual axis has its image to the left of the yellow spot, an object situated to the left of the visual axis has its image to the right of the yellow spot, and the same applies, *mutatis mutandis*, to objects situated above and below. We mentally refer objects to their proper relative positions in the external world by the psychological action of *projection*, which we learn by experience and the aid of the muscular sense, *i.e.*, the knowledge of the exact degree of nerve-force necessary to control the normal action of individual muscles.

False projection, or seeing objects in the wrong place, is the result of an erroneous idea being formed as to the position of the eye due to the loss of muscular sense in consequence of paralysis of one or more of the ocular muscles. It generally causes visual vertigo.

Tests for Binocular Single Vision.—The existence or absence of binocular vision may be ascertained in several ways.

(*a*) Take patient into a dark room and require him to fix a lighted candle held six metres off in the median horizontal plane, and cover first one eye and then the other with a card. If the patient fix the object accurately, no deviation of the eye behind the cover will be noticed, nor when the cover is removed. Suppose, however, that one eye does deviate, then on placing the cover in front of the fixing eye, *a movement of adjustment* will be observed to take place in the other eye so that it may fix the object.

(*b*) *Prism Test.*—Place in front of one of the eyes a prism of 10°, base down, and direct patient to look at a candle-flame situated at a distance of six metres, and on the same plane with the eyes. If binocular single vision exists, *vertical diplopia* is induced, *i.e.*, two images will be seen, one standing over the other, If the prism cause no diplopia, this is evidence of the absence of binocular vision.

One of the best proofs of the presence or absence of binocular vision is the experiment with falling bodies known as the

(*c*) *Stereoscopic Test of Hering.*—This is conducted by means of a long tube, inside which is extended a vertically-placed thread. The patient is directed to look through the tube with both eyes, while glass beads are dropped, sometimes in front, and sometimes behind, the thread. If binocular vision be present, no mistake will be made with regard to the true position of the beads with respect to the thread; while on the contrary, if only monocular vision exist, frequent mistakes will be made in judging of the proper situation of the beads.

Movements of the Eyes. The Eye Muscles.

The movements of the eyeball in the orbital cavity may be likened to those of a ball-and-socket joint, the globe as a whole undergoing no change of position but rotating round an immovable point, *the centre of rotation* (situated on optic axis 11 mm. from vertex of cornea).

Field of Fixation indicates the limits of movements of the two eyes, *the head being kept still*, when directing them to the four points of the compass. *It is the sum of all those points in space which the eyes can dominate.* It is measured by the perimeter in the following way: Fix patient's head on the "rest" with the eyes directed to the zero-mark, and one screened. Then move test-types along the quadrant from the periphery towards the centre, and note the exact position in which the letters can be read distinctly, recording the result on the perimetric chart. In the normal eye the field is about 45° upwards, inwards and outwards, and about 55° downwards.

Movements of Eyes.

The *primary position*, or *position of rest*, of the eyes, is that in which, with head erect, the visual axes are parallel, horizontal, and directed straight in front. This is the position of rest, and all other positions are *secondary*. (*a*)

The secondary positions are movements of rotation

(*a*) It is to be understood, however, that this statement applies strictly speaking to emmetropia alone, for according to Stilling, in the large majority of cases of *hypermetropia* the eyes converge in a state of repose, while in myopia they diverge in a state of repose.

round three primary axes, which together form a co-ordinate system :—

(*a*) A vertical axis about which the movements are lateral, to the right and left.

(*b*) A horizontal axis, at right angles to (*a*), about which the movements are up and down.

(*c*) An antero-posterior axis, about which the movements are wheel-like or those of torsion, the upper end of the vertical meridian inclining inwards or outwards.

The visual axes are parallel when the object of fixation is distant (*i.e.*, 20 ft. or more), and converge to the same point when the object of fixation is near (*i.e.*, less than 20 ft.). Any other position of the axes is an abnormality.

Extra-ocular muscles.—The globe is rotated round its three principal axes by the individual, or joint, action of six muscles, all of which, with the exception of the inferior oblique, arise from the apex of the pyramidal-shaped orbit.

	Length of tendon.	Distance of insertion from cornea.
Internal rectus	8·8 mm. ...	5·5 mm.
Inferior rectus	5·5 mm. ...	6·5 mm.
External rectus	3·7 mm. ...	6·9 mm.
Superior rectus	5·8 mm. ...	7·7 mm.

—Merkel and Fuchs.

The muscles may be divided into three antagonistic pairs, one muscle of the pair acting like a bridle to the other, being in co-operative antagonism to it, viz. :—(*a*) External and internal recti rotate eye round vertical axis; (*b*) superior rectus and inferior rectus rotate eye round horizontal axis; (*c*) superior oblique and inferior oblique rotate eye round antero-posterior axis.

External rectus rotates the eye outwards.
Internal rectus „ „ inwards.
Superior rectus „ „ upwards and inwards.
Inferior rectus „ „ downwards and inwards.
Superior oblique „ „ downwards and outwards.
Inferior oblique „ „ upwards and outwards.

While rotation vertically upwards is produced by the combined action of superior rectus and inferior oblique, and rotation vertically downwards by the combined action of the inferior rectus and superior oblique.

To be quite correct, it must be understood *that only the internal and external recti of the one eye are genuine antagonists*, in the sense that if one is paralysed the result is the same as if the other had contracted. With regard to the remaining pairs of muscles, there is no such thing as a perfect antagonism between them; for example, the superior oblique cannot be strictly regarded as the true antagonist of the inferior oblique, nor the superior rectus of the inferior rectus. To put the matter briefly, the antagonist of one of these muscles is not solely the other muscle which rotates the eye round the same axis in an opposite direction, but would be represented by the sum of the forces exerted by several other assisting muscles which act as opponents.

The muscles are innervated by the third, fourth, and sixth nerves, the motor neurons of which are located along the floor of the aqueduct of Sylvius and the forepart of the floor of the fourth ventricle. These motor neurons are under the control of a higher co-ordinating centre, which in its turn is connected with a supreme voluntary motor centre in the cortex.

(To be continued.)

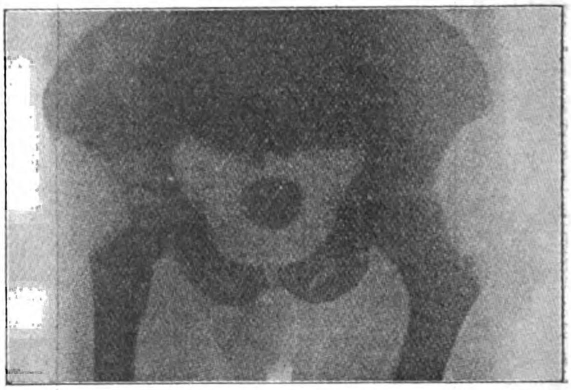
The Nature Study Exhibition was opened by the Duchess of Devonshire at the Botanic Gardens on July 23rd, and will remain open until August 5th.

NOTES ON THE OPERATION OF SUPRA-PUBIC LITHOTOMY, WITH SKIAGRAPH SHOWING STONE IN THE BLADDER.

By DENIS KENNEDY, F.R.C.S.I.,
Surgeon to the Children's Hospital, Temple Street, Dublin.

J. D., ÆT. 3, was admitted to the Children's Hospital, Temple Street, on November 15th, 1901. For the previous twelve months he had complained of pain on passing water, and for the previous three months his pain had increased very much. In hospital he suffered a good deal for some minutes previous to micturating, and was in great pain all through the act. On examination under an anæsthetic a stone was easily felt with a sound, and could also be felt per rectum. He had well-marked phimosis.

Being anxious to test the value of skiagraphy for diagnosis in cases of stone, I had the X-rays applied, and the skiagraph here published is the result. The stone is seen lying about the level of the true pelvic brim, having evidently gravitated to the fundus of the bladder, as the boy was lying on his back for the operation. It was nearly the size of a small hen's egg.



On considering what operation I should do for the relief of the condition, I decided to do a suprapubic lithotomy, although I am well aware that many cases of successful crushing, even in very young boys, have been recorded by Messrs. Keegan and Frere. The reasons I decided not to do litholapaxy in my case were the following:—First, the size of the stone, as was shown in the skiagraph, would make the operation prolonged and difficult. Secondly, on account of the stone showing so well in the skiagraph, I was of opinion it was made up of hard material, such as oxalate of lime. Thirdly, it is difficult to get a lithotrite and evacuating catheter small enough to pass through the urethra of a young boy, and at the same time to be effectual. And, lastly, the comparatively few cases of stone in boys we meet with in Dublin, makes it difficult for a Dublin surgeon to acquire the necessary skill to manipulate the lithotrite without danger of injury to the urethra and bladder, which are so delicate in these young subjects. In the Children's Hospital, Temple Street, during the past year, we had only four cases of stone in the bladder out of close on 3,000 cases that were attended at the hospital, either in the wards or in the out-patient department. Even this is nearly a record number, as one or two in the year is the usual number.

In comparing the suprapubic with the perineal route, I consider the former has many and decided advantages over the latter. In suprapubic cystotomy the operation can be carried out deliberately step by step; we know exactly what we are cutting; a much larger stone can be extracted; if the wound in the bladder is closed, as can be frequently done, union takes place in a few days, and the dangers of the operation should be less than in the perineal method. During the past year I have performed the suprapubic operation three times, all on boys under four years, and in each case the patient was fit to be up on the eighth day, as soon as the stitches were removed, the wound being then perfectly healed.

In carrying out the suprapubic operation in this and other cases, the details which I consider worthy of notice and which differ from the usual routine are: First, I used no rectal bag; instead, I put the patient in the Trendelenberg position. On incising down to the bladder I found the peritoneum well drawn up leaving ample room for extracting the stone without interfering with that membrane. Secondly, instead of using a hook to lift up the bladder and hold it in position, I passed two temporary silk sutures through the muscular coat, one just below the reflection of the peritoneum, the other above the pubes. By this means my assistant was enabled to keep the bladder well forward against the abdominal wall, the danger of the bladder falling back into the pelvis was obviated, the stone was extracted with greater ease, and suturing of the bladder wall was carried out with accuracy and rapidity. The plan is recommended by Kocker. Lastly, I sutured the wound in the bladder with interrupted Lembert's sutures, and in each case obtained union by first intention.

As a skiagraph of a stone in the bladder is rarely possible to obtain, I need scarcely apologise for publishing this one. The stone was made up completely of phosphates. The boy left hospital cured on the twelfth day after operation.

A CASE OF ASCENDING PARALYSIS. (a)

By ALFRED R. PARSONS, M.D.Dub., F.R.C.P.I.,
Physician to the Royal City of Dublin Hospital, and to the National Hospital for Consumption.

In 1859 Landry published a paper based on ten cases of ascending motor paralysis. He named the condition "Paralysie Extenso-Progressive" or "Paralysie Ascendante Aiguë." Subsequent writers have described the disease under the latter of these terms, or often for sake of brevity as "Landry's Paralysis." In one of the ten cases which proved fatal on the ninth day no lesion was found in the brain or spinal cord. Landry, influenced by the negative results of this autopsy and by the absence of bed-sores, urinary troubles, and pain in the back in all the cases, suggested that the possible cause of the paralysis was to be sought for in some disease of the nerves. The hypothesis that paralytic phenomena not produced by cerebral or spinal disease may arise from some lesion of the nerves was not propounded for the first time by Landry. It was a distinguished member of the Irish School of Medicine, Robert J. Graves, who first suggested that extensive paralysis without any lesion of the brain or spinal cord may arise from disease commencing and originating in the nervous extremities alone.

Notwithstanding the numerous advances in neuropathology during the past forty years since Landry suggested that the nerve-trunks were the seat of the lesion in his cases, it must, I think, be admitted that the riddle of the pathology of Landry's acute ascending paralysis is still unsolved.

The comparative rarity of cases of ascending paralysis and the obscurity of their nature will, I trust, be a sufficient excuse for presenting to this Academy the following clinical record:—

J. M., æt. 38, by occupation a labourer, was admitted to the Royal City of Dublin Hospital on Saturday, September 21st, complaining of weakness in his arms and legs. He states that the first symptom he noticed was a numbness in his feet extending to just below the ankles, about 12.30 p.m. on Saturday, September 14th. He went home at 5.30 p.m. and put his feet into hot water to try if he could stop this feeling, but obtained no relief. On Monday, September 16th, the numbness had advanced half-way up his calves, but his walking power was not interfered with. On the following day the numbness extended to a little above his knee, and he found that he could not walk as well as formerly. By Wednesday the numbness had reached his umbilicus, and as the difficulty in walking was more marked, he consulted my colleague, Mr. Moore, at the extern department, who kindly directed him to come to my dispensary on the following day. The weakness in his legs was so evident on Thursday that he was unable to go to work. He walked into the consulting-room of the extern department with manifest difficulty. There was then no appreciable loss of power in his arms, but when asked to sit on the edge of a table for the purpose of examining his reflexes, and then told to jump down, his legs gave way under him and he had considerable difficulty in preventing himself from falling. On Thursday night, the numbness went up along his sides and down his arms, and on the following Saturday, one week after the commencement of his symptoms, he was admitted to hospital. He was able, though with considerable difficulty, to walk into the hospital, and on the day following he walked from the ward to the lavatory, a distance of twenty-five yards, without assistance. On September 23rd and 24th, with help from a couple of men, he was able to walk the same distance, but on September 25th he was quite unable to get out of bed.

Previous History.—He served as a soldier for some years, and was discharged owing to an injury to an eyelid, the result of a gunpowder explosion. He states that he never had syphilis. His family history is good, and the only point noted about his personal habits is that he usually drank from four to six pints of porter a day.

Physical Examination.—On September 25th and subsequently, a detailed examination of his nervous system was made.

Cranial Nerves.—Functions intact and nothing abnormal detected, except slight fibrillary tremor in the tongue.

Upper Extremities.—These can be moved freely in all directions, but the grasp is feeble in each hand, and if the patient be directed to keep his arm flexed and an attempt be made to extend it, the muscles yield, and the limb is too readily straightened. There is no wrist drop; in fact, the wrist can be extended against slight resistance. Co-ordination and sensation to touch and pain seem perfectly normal. A pin can be picked up off a hard surface without difficulty. Muscle sense is also normal. Among the vaso-motor and trophic phenomena it was noted that the hands were cold and clammy, that the skin was normal, but that the muscles were flabby. The muscles reacted perfectly to the faradic current.

Trunk.—(1) Thorax: Movements were good. The diaphragm moved well. No loss of sensation to pain, touch, or temperature. Percussion and auscultation revealed nothing abnormal. (2) Abdomen: Spleen not palpable. Area of splenic and of hepatic dulness normal. Full control over bladder and rectum. The patient is, however, unable to sit up in bed except by raising himself on his elbows and then supporting himself on his hands. Sensation to touch, pain, and temperature was normal over the abdomen. The superficial abdominal reflexes were not obtained, but there was no difficulty in eliciting the cremasteric reflex. There was no pain in the spinal column.

(a) Read before the Medical Section of the Royal Academy of Medicine in Ireland, May 16th, 1902.

Lower Extremities.—The loss of power is not absolute in the lower extremities. Movements are, however, extremely feeble, and prevented by slight resistance, except adduction of the thighs, which is fairly good. There were no sensory disturbances. The superficial and deep reflexes were abolished. The feet were cold and covered with perspiration, and the muscles were flabby.

The loss of power in the leg, arm, and trunk muscles became more and more marked, so that he was unable to separate his legs if they were placed in contact or to raise himself in bed. His hands, however, did not become absolutely paralysed, and, at his worst, if his dinner were cut up for him and placed on a chair at his bedside, he could by rolling on his side and getting his face nearly into contact with the plate introduce the food with a spoon into his mouth.

October 14th.—Mr. Arthur Benson examined his eyes and found the light reflex normal, that the pupils contracted for accommodation and the fundus was also normal.

October 15th.—Some indications of returning power in the lower extremities were noticed. He could slightly flex the limbs so that the posterior surface of the knee was six inches from the bed. He could separate his heels to a distance of seven inches by working them out along the bed. He could not raise the heels off the bed, but if separated he can approximate them. The plantar, abdominal, and epigastric reflexes were still absent. The calf and thigh muscles were somewhat wasted, and were tender on firm pressure. He was unable to sit up in bed, and there was little power in the upper extremities. Sensation to touch, pain, and temperature was unimpaired.

October 19th.—Muscles of upper and lower extremities contracted on faradic stimulation.

October 24th.—He was able to be propped up in bed with pillows for dinner. The day following he was able to raise his right leg more than two feet off the bed, but his left heel only one inch.

October 26th.—For the first time in his illness he complained of a great pain and tenderness in the calf of the left leg. A few days later this calf seemed a little fuller than that of the right leg.

November 3rd.—Pain in calf of each leg, which was so severe that it kept him awake the previous night. Two days later he was free from pain, and on the 17th he was allowed up.

December 8th.—He could nearly stand alone, and was able to walk a little without aid.

January 18th.—Rapid progress since last note. The patient could walk well, could stand on either leg, and nearly hop. The knee-jerks were still absent, though tone and nutrition of muscles were good. He was discharged from hospital.

April 8th.—He walked up to the hospital to know if he might work on roofs. The knee-jerks were still absent.

April 11th.—He felt perfectly well, except that he was more tired after his work than formerly.

The treatment adopted in this case was massage and stimulating liniments for the upper and lower extremities, and strychnine in increasing doses was administered internally.

The chief features of this case may be briefly summarised as follows:—A feeling of numbness commencing in the soles, gradually spreading upwards, and in a few days involving the trunk and arms. Three days subsequent to the onset of sensory symptoms there was loss of power in the legs. This motor paresis likewise extended upwards, involved some of the trunk muscles and the upper extremities, but did not affect the muscles of respiration, the muscles connecting the head with the trunk, or any muscles supplied by the cranial nerves. In the paralysed parts careful examination failed to reveal any loss of sensation to pain, touch, or temperature. There was abolition of the superficial and of the deep reflexes. The muscles were rather flabby, they wasted slightly, but maintained their faradic contractility. Vaso-motor disturbances were in abeyance, except the coldness and sweating of the hands and feet be regarded as such.

The most pronounced symptom in the case was an almost purely motor paralysis with abolition of the deep reflexes. In attempting to localise the lesion we may follow Sir William Gowers, who believes that the spinal cord is the part primarily affected, and that the terminal filaments of the upper motor neurons, as they are passing to the ganglionic cells in the anterior cornua, bear the brunt of the disease. In support of this hypothesis may be adduced the presence of histological changes in the grey matter in a few cases. It is furthermore favoured by the persistence of the faradic contractility in the muscles, the absence of any marked degree of wasting, and the comparative slightness of the sensory phenomena. On the other hand, this localisation does not seem to satisfactorily explain the long duration of the absence of the knee-jerk, which "in the majority of cases does not return until all paralytic symptoms have disappeared" (Gowers). Influenced by this fact, and by the similarity in the ætiology of cases reported as Landry's disease, and the well-recognised causes of multiple peripheral neuritis, some recent writers (Ross, Bury, and Osler) feel, as indeed Landry himself did, that the lesion is more probably in the nerves than in the spinal cord. If this latter view be correct, we may imagine the disease to be produced by one, or possibly several, toxic substances which have the property of acting mainly on the lower motor neurons, and slightly, if at all, on the sensory neurons.

INFANT LIFE PROTECTION. (a)

By T. N. KELYNACK, M.D., M.R.C.P.,

Assistant Physician to Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood, London.

THE subject of infant life protection must be approached in a truly scientific spirit. Around it cluster many problems. Progress may be secured by different methods. It will not necessarily come by insistence on the promulgation of the views of any particular school. While considering special phases of the question it is very necessary not to ascribe to one particular agency the whole effect of a plurality of causes.

Gloomy facts have to be faced: the birth-rate is steadily falling, the infant death-rate is excessively high, and the multiplication goes on apace of those who from weakness of body or feebleness of mind are unfitted to play a useful part in the up-building of the State.

According to the recent returns of the Registrar-General, the births registered during 1900 were equal to a rate of 28·7 per 1,000 persons living. This is the lowest rate on record, and is 1·3 per 1,000 below the mean rate in the ten years 1890-99. The rate has decreased year by year since 1895, when it stood at 30·2 per 1,000. (*a*)

(a) Abstract of Introduction to a Discussion on the Protection of Infant Life, at the International Congress for the Welfare and Protection of Children, London, Wednesday, July 16th, 1902.

It is well to remember that in England the maximum birth-rate was 36·3 per 1,000 of population in 1876. This marked and rapid fall in the birth-rate is undoubtedly due to a "deliberate and voluntary avoidance of child-bearing on the part of a steadily increasing number of married persons." (*b*)

In the year 1900 the proportion of deaths of infants under one year of age to registered births was 154 per 1,000, against an average of 153 per 1,000 in the ten years 1890-99. It is important to notice the marked variation and wide range in different parts of the country:—"Seventy-nine in Rutlandshire, 91 in Dorsetshire, 94 in Wiltshire, 100 in Oxfordshire, and 106 in Herefordshire, to 175 in Warwickshire, 176 in Nottinghamshire, 178 in Staffordshire, 179 in the East Riding of Yorkshire, and 180 in Lancashire."

But it is not wise to attempt to prove too much from figures. Statistics have their limitations. Our present methods of computation are open to many objections, and much care is necessary to avoid arriving at imperfect or actually fallacious conclusions.

It must also be remembered that an immense amount of injury is constantly being wrought to mothers and children which cannot be adequately indicated in annual statements, but the proof of which lies buried in blue books, hospital returns, and reports of medical officers of health, or stored up in the private note-books of inspectors and visitors working in connection with various philanthropic institutions.

In studying the problem as it presents in England it is well to remember that it is one which more or less concerns all parts of the Empire, and therefore the principles guiding action should be such as can be of universal application.

And it is well also to recognise that many other European countries are face to face with this problem. (*c*)

France especially is making great efforts to arrest the depopulation of the country and to adequately protect its children. (See the valuable monograph of MM. les Drs. Ballestre et Gilletta, of Nice: "Etude sur la Mortalité de la première Enfance dans la Population urbane de la France de 1892 à 1897" (1901); and Dr. Pierre Budin's reports on the same in *La Revue Philanthropique*, 10 juillet, 1901, and 10 janvier, 1902.)

The law associated with the name of Roussel has sought to secure legal protection for the infants of France, and although unsatisfactory in some ways, nevertheless provides for a certain degree of medical inspection of nursed children, and in other ways has undoubtedly proved beneficial.

In Russia it is said only 732 infants out of every 1,000 born survive their first year. Here however, the mortality in towns is said to be less than among the peasantry.

In America much is being accomplished for the preservation and betterment of infant life.

And even in the Argentine Republic (*d*) and other countries little known to us efforts are being made to secure legal protection for infants.

Even under the best possible conditions considerable infant mortality occurs. In Norway, which can boast of having the lowest infant death-rate among European countries, it is 100 per 1,000. In certain agricultural districts in this country, it is less than this, although the average proportion of deaths of infants under one year of age to registered births during 1900 was 154 per 1,000. (*e*)

It is necessary to insist on a division of infantile deaths into those from what may be called (1) natural causes, *e.g.*, those which in the present state of our knowledge, and with our limited means of control, are considered non-preventible; and (2) avoidable or strictly preventible causes. Roughly speaking, the natural infant mortality may be taken as being about 100 per 1,000, although, with increasing knowledge, this will doubtless be lowered.

The chief influences making for excessive infantile mortality arise from the ignorance, inexperience, apathy, carelessness and neglect of the mothers, or those having the care of the children. Improper feeding, insufficient clothing, and general domestic mismanagement account for much of the excessive mortality. Among the infantile diseases arising from ignorance and neglect, the most important are the acute inflammatory disorders of the alimentary tract, summer diarrhœa, respiratory affection, tuberculosis, various infectious diseases and numerous nutritional disorders.

The death-rate of illegitimate children is exceedingly high. While illegitimate births form less than 5 per cent. of the total number of births, yet the inquests on illegitimate children under one year of age amount to 31 per cent. of the inquests held on infants. (*a*)

In many instances these illegitimate children are the offspring of degenerate parents, the mother is commonly immature, and often both physically and mentally deficient, and "not infrequently attempts at abortion have been made during early pregnancy." In many cases there has been much mental worry, anxiety, and recklessness during the pregnancy, and in not a few there has been a neglected confinement. In some instances the infant is born with a distinct taint, and not infrequently is the subject of congenital disease. In short, it is necessary to recognise that there are special ante- as well as post-natal causes for the excessive mortality of the illegitimate infants. (*b*)

Much has been said respecting the employment of pregnant and nursing women in factories. Undoubtedly the local differences in the infant death-rate may in great part be explained on this ground.

Dr. Reid (*c*) has shown that marked differences exist in the infant mortality rate of the northern and southern towns of the county of Stafford, and that there had been an increase in the infant death-rate of nearly 27 per cent. in those artisan towns in which married women were largely engaged in factory labour. Factory life is undoubtedly prejudicial to the pregnant woman, highly detrimental to the nursing mother, and proves a serious danger to the welfare of the child. Much of infant mortality and sickness, the blighting of physical growth of the child, and stunting in its mental development arises from the neglect to which the child is exposed consequent on the employment of the mother in the factory. The practice is fraught with danger to the race. Restrictions such as that which makes it illegal for a mother to return to work within one month of confinement are intended to benefit the mother rather than secure conditions for healthy development of the child. (*d*)

Factory work certainly discourages suckling. Many sanitarians have advocated the extension of the period of one month to three months, thus as far as possible securing natural feeding for the infant during the most precarious period of its existence. It is interesting to note also that in France efforts have been made to make it illegal to employ a pregnant woman for three months before her confinement.

In only too many instances the neglected infant of the one generation becomes the neglecting mother of the next.

While one cannot help sympathising with the objects of those who would greatly restrict or wholly prohibit the employment of female labour during the child-bear-

(*d*) A month is the period of abstention from work prescribed since 1891 under the Factory Act.

ing and nursing period, it is necessary to remember that the grave social and economic difficulties which surround the present situation are such as to render the application of stringent measures at present peculiarly dangerous.

In regard to the employment of women in factories, workshops, or in home work, it would seem best that, at least at present, efforts should be directed not so much to the negative side of prohibiting and restricting work as to the positive side of securing improved conditions for the workers. It would be advantageous if measures could be found whereby working mothers could be encouraged to nurse their infants. Even Spain can teach us something in this respect, for there employers must allow "one hour in the ordinary period of employment (from which there must be no deduction from wages) to nursing mothers to nurse their infants. This hour may be divided into two separate absences of half-an-hour, and may be fixed at pleasure by the mother, whose only obligation is to notify the time she chooses to the overlooker. (*a*)

As far as I can gather, the restrictions are such that at the present time there is but little encouragement to insure an infant from criminal motives.

Alcoholic habits in the parents, and particularly alcoholism in the mother, is peculiarly prejudicial to healthy infant development. As illustrating the risk of accidental death directly arising from acute alcoholism I need only refer to the observation of Dr. Hugh R. Jones, of Liverpool, who has shown that "The parallelism between the figures relating to drunkenness and suffocation in bed is extraordinary." (*b*)

There is reason to believe that the custom of administering opiates to infants still prevails to a very dangerous extent.

In seeking to secure a more adequate protection for child life there is need for private and public effort, domestic, municipal and national enterprise.

State control must necessarily prove ineffective in practice unless supported and enforced by public opinion. Any interference beyond that recognised as righteous by the conscience of the community can hardly be expected to result in lasting benefit. And while proclaiming the importance of national or collective responsibility it is very needful to enforce the claims of individual or personal duty. A healthy public opinion might do much to strengthen existing laws relating to protection of child life, and more should be done to encourage philanthropic, humanitarian and religious effort to adopt scientific procedures in their measures for prevention, restoration and amelioration. The propriety and right of the State to enforce compliance with sanitary laws and to protect the helpless has long been recognised.

Something has already been accomplished by judicious State interference.

The Infant Life Protection Act of 1897 has undoubtedly been of much service, and indirectly has proved of considerable educational value. It is much to be regretted that local apathy and indifference has done much to limit its usefulness. But practical experience has shown that the Act is too restricted in its application, and that there is urgent need to extend and amend the same.

The more important extensions of the provisions of the Act now much required may be briefly indicated:

1. The abolition of the distinction made in the present Act between one and more than one infant. The dangers to the life of each individual infant taken in to nurse are of the same nature, and arise from the same causes as those to two infants.

2. The abolition of the distinction made in the present Act in consideration of a sum of money paid down. In the case when a mother can afford to pay down £20 the nature and needs of a baby, and the dangers to which it may be exposed, are precisely the same as in the case of a baby where a mother cannot afford to do so.

3. It is also desirable to amend the Act in order to render any person failing to notify the reception of an infant adopted in consideration of a lump sum payment to fine as well as to forfeiture of the amount received.

4. It is also desirable that notice should be required to be given of all changes of residence of a person having the care or custody of children within the Act.

5. It has also been proposed that the age limit of protection should be extended to under seven years. Probably to under five years would be sufficient.

6. It has also been urged that it should be provided in the Act that in any proceedings taken under it in any court it should not be necessary that the name of the mother of a child on whose behalf they are taken should be disclosed.

Objections have been raised in certain quarters to the inclusion of one-child cases under the Act, but after careful consideration and consultation with those engaged in the best forms of rescue work and the conduct of the most successful children's homes and movements for the care and protection of children, I am convinced that such objections must not be allowed any serious weight when compared with the immense advantages which would accrue both to mother and child from the proposed extension of the Act.

Investigation seems to prove conclusively that where the conditions are suitable for the care of infant life inspection is not only not objected to but actually welcomed, and certainly those women most solicitous for the care of their offspring do not complain of a supervision when they understand that it is for the benefit of their child.

The principal of one of the most successful homes in the country writes me as follows:—"A well-managed institution would not find itself in any way hampered by inspection, and often the official oversight would be a valuable check upon the institution itself."

Of course, inspection will be useless, or it may be actually prejudicial, unless efficiently carried out. Only intelligent, tactful women, with experience and some common sense, should be employed. Mere man is quite unsuited for an inspector where babies are concerned. And it must be remembered that inspection, so called, should form but a part of the work of the inspector. The preventive and educational aspects of inspection must not be overlooked. The inspector should be capable of serving as instructor and adviser. Medical women might be of much assistance in this work. Certainly every inspector should be well informed concerning the hygiene of infant life, and must be acquainted with all the perplexities and dangers of artificial feeding. She should also have had some practical experience in nursing, and possess a working knowledge as to medical requirements. But while seeking for strict control over all infants nursed for profit, it must be realised that baby farming, as it is sometimes called, when rightly conducted, may be not only a legitimate, but even a praiseworthy occupation. Everyone taking a child to nurse for profit should be registered.

There is reason to believe that in some cases at least ill-directed measures to secure the safety of the child have tended to encourage the vicious life of the mother.

The provision of skilled obstetrical assistance for the poor would undoubtedly go far in saving life and preventing disease. In seeking to secure hygienic necessities for healthy development, while assistance may rightly be expected from legislative measures, chief reliance must be placed on educational effort. Some persons take interest in the question now under discussion, mainly for the sake of the mothers, others more particularly for the sake of the children. The point of view should not be thus restricted, for the subject is of national importance. Efforts should be made to ensure rational instruction in hygienic principles in all public schools, particularly to girls. Detailed instruction in the conduct of domestic duties should form an important part in every girl's training. Much may be done by personal and private enterprise. Judicious house-to-house visitation by unpaid workers has proved of service in many districts. Much good might be accomplished if it were possible to increase the number of suitable women inspectors.

Formation of local infant life protection societies is

(*a*) "Dangerous Trades." Edited by Dr. T. Oliver. 1902. Pp. 54.

(*b*) Dr. Hugh R. Jones, *Jour. of the Royal Stat. Soc.*, March, 1894.

to be encouraged, and in some large cities much good has been accomplished by the voluntary efforts of ladies' health societies and the like. It is a pleasure as well as a duty to acknowledge the good work being accomplished by various humanitarian, philanthropic and religious organisations. The "Settlement" movement especially is one which should do much in bringing hygienic enlightenment to many a dark district.

In many centres the public health authorities provide means for the spread of accurate knowledge regarding the care of children. Not a few hospitals are doing much good educational work in the dissemination of information respecting the rational nursing of infants. But the scientific feeding-bottle is not popular, and the old-fashioned death-dealing feeding-bottle with its filthy tubing still reigns supreme in many a home.

There is need for education in every section of society. Women in all ranks of life should be taught to realise the duty of nursing their own offspring.

It seems unfortunate that English prejudice and the economic conditions prevailing in this country prevent the adoption of a system similar to the German compulsory assurance method, whereby the working woman, while prevented from working owing to childbirth, receives a sum equal to half her ordinary daily wage. But while philanthropic attempts to establish day nurseries merit approval, it is well to remember that such efforts are mainly symptomatic and palliative.

There is need to adopt progressive measures. We must shake ourselves loose from our constitutional British lethargy, break away from national prejudices and the insular habit of mind, and admit the necessity of learning in relation to this matter from our Colonial brethren, our American cousins, and our Continental neighbours. In America the municipal supervision of the milk supply of such cities as Chicago has resulted in an immense saving of child life.

In Berlin, scientific care in the distribution of milk during the ten years 1890 to 1899 is said to have produced a reduction of 13·6 per cent. in the infant death-rate.

It is interesting to note that efforts are being made to obtain adequate training for nursemaids. The risks to the infants of the well-to-do from the ignorance of nurses is apt to be overlooked.

In not a few places provision is made with advantage for the supply to the poor of properly sterilised and suitably modified milk.

All rational efforts to check the spread of alcoholism, particularly among women, and to mitigate the evils flowing therefrom should receive vigorous support. Every effort which seeks to encourage personal and public hygiene is deserving of sympathetic consideration.

In conclusion, it may be safely affirmed that the excessive infantile mortality, subnormal development and actual disease in children is to a great extent the outcome of avoidable causes, preventible conditions, and removable influences. Ignorance is the chief ætiological agent, and to education we must look for the surest way of relief, and the only adequate channel whereby we may secure national efficiency.

Clinical Records.

A CASE OF ACUTE INFLAMMATION OF THE BLADDER, WITH PELVIC CELLULITIS IN A PATIENT SUFFERING FROM ADVANCED BRIGHT'S DISEASE:

ON BOARD H.M. HIRED TRANSPORT "TAGUS."

By LOUIS VINTRAS, M.D.,

Late Medical Officer to the Ship; Physician to the French Hospital.

G. A., troop-storekeeper, was taken ill on August 4th, 1901, while the *Tagus* was returning to the Cape from New Zealand, where she had taken back the 4th and 5th Contingents of the troops sent from that Colony. He complained of pain across the loins, a dull pain deep in the pelvis, and there was much tenderness over the bladder. His skin was dry, his tongue furred, and his temperature 102°. He told me he had been suffering for some years from kidney trouble, and a year and a half before had been in hospital for several months. During the outward voyage he had felt ill, but had had no time to attend to himself. We had had an almost unremitting series of storms on the outward voyage, and while crossing the Southern Seas the weather had been bitterly cold, it being then mid-winter in those regions. He also admitted having drunk heavily while we were in Wellington. His urine was smoky, and contained one-third of albumin. The next day his temperature was 104° in the morning and 103° in the evening. His pulse was quick. He passed a sufficient quantity of water. On the 7th his condition improved, and his temperature, which was 102° in the morning, fell to 100° in the evening; the skin began to act and the bowels were kept freely open. On the 8th the improvement was maintained. Unfortunately, he was a man of very active habits and very desirous to be about; feeling so much better he left his bunk when alone, several times during the day, and sat up in his quarters. In the evening the pain in the pelvis returned more acutely, and his temperature, which had remained at 100°, began to rise, reaching during the night 101·6° and the next morning 102°. By midday it was 103°. The urine was quite dark with blood, shreds of mucous membrane were present and its odour was offensive. There was great tenderness over the bladder and on each side, more especially the right. A No. 4 gum elastic catheter was passed with difficulty, as there was an old stricture, and the bladder was washed out. The temperature in the evening was 103·5°.

The next morning the tenderness over and around the bladder was even more pronounced, and on the right side there was distinct redness of the skin, and there was some puffiness over the pubes; but no sign of localised pus at any point. The bladder now ceased to react properly, and there was some retention. On trying to pass the catheter again, there was much irritability and spasm, and hot flannels had to be applied, after which a No. 2 gum elastic was introduced with difficulty. This was tied in, and the urine allowed to flow constantly through a long tube to a receptacle under the bed. The water was now exceedingly offensive, and there was a thick sediment. A marked feature of the case was the patient's comparative freedom from pain. The penis and scrotum were now œdematous; the redness of the skin on either side of the bladder had increased and assumed a mottled appearance. On the 11th the temperature was 101·2° in the morning, 102·5° in the afternoon, and 102° in the evening. The œdema of the scrotum having increased, punctures were made which relieved the swelling a little. On the evening of the 13th the skin of the scrotum began to slough and the patient's breathing became impaired. There were signs that the inflammation was gaining the abdomen. There was still hardly any pain and notwithstanding the intensity of the inflammatory process and the extent of the tissues involved, the patient repeatedly declared himself to be comparatively easy. He died on the 15th, when his breathing which had improved the day before had again become stertorous. He remained fully conscious and took nourishment to within two hours of the end. The patient was a thin, weak-looking man of thirty-two, with the facies peculiar to those suffering from wasting diseases. The general treatment consisted of antimony, digitalis, nux vomica and dilute hydrochloric acid every four hours, with five-grain doses of quinine twice and later three times a day. The bowels were kept freely open. The diet consisted of beef tea, milk, chicken and fish; while stimulants, port and brandy, were given at regular intervals. Hot fomentations were applied every two hours to the abdomen, and when sloughing began the parts were dressed with cyanide gauze and iodoform.

The points of the case are the intensity and rapidity with which the morbid process extended, involving the whole walls of the bladder from the first and extending to the surrounding cellular tissue and to the entire pelvis, apparently killing right away the tissues debilitated by long-standing disease, without localising itself at any one spot and affording any guide as to possible surgical interference. The cellulitis appeared to coincide with the onset of the cystitis.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, July 27th, 1902.

Cardiac Affections and Cactus Grandiflorus.

According to Professor Zeleusky, cactus grandiflorus, recommended in heart affections of every nature, was more particularly beneficial in aortic lesions. Although it produced certain favourable results in mitral disease, such as attenuation of the dyspnœa and increase of diuresis, yet they were only transitory, and modified in no way the circulation. It was quite otherwise in the case of affections of the aortic orifice; the cactus grandiflorus moderated the irregular rhythm of the heart, and caused to disappear œdema and ascites when present. As to the preparations of the drug, he preferred the fluid extract to the tincture, and gave thirty drops three times a day.

Beer Yeast and Pulmonary Affections.

According to Dr. Lardier, the administration of beer yeast constitutes an excellent agent in the treatment of acute and chronic bronchitis in the aged. In the case of the former, as soon as the acute stage had passed and the patient began to expectorate, dry yeast at the dose of two or three teaspoonsful daily considerably diminished the secretion, and in one or two weeks the patient was convalescent. In old catarrh cases, no matter how abundant was the expectoration, the employment of the yeast produced a rapid decrease in the bronchial secretion, and finally a complete cure in the space of two to three weeks. However, in order to ensure the result, M. Lardier recommended the drug to be continued for ten or fifteen days longer. Further, those who are predisposed to the affection were advised to have recourse to the yeast for one month at the beginning of winter and that in the absence of any symptoms. At the period of defervescence in pneumonia of aged persons, our *confrère* recommends the same treatment, claiming for it the best results.

The yeast is given in the dry state in water or milk or in the form of wafers, if the taste was obnoxious to the patients.

Meningitis.

Professor Tripier, of Lyons, treats all cases of suspected meningitis with blisters to the head. The head being shaved, small blisters are applied every day. In the last series of six cases published, the treatment succeeded in arresting the malady. One of the patients succumbed to a relapse a year afterwards, however, but the second time no blisters were used.

M. Tripier is of opinion that in every case where the patient shows symptoms resembling that of meningitis *au début*, a series of blisters should be applied to the head without waiting for confirmation of the diagnosis, otherwise the malady might gain a point which would render all treatment useless.

Appendicitis.

M. Dieulafoy communicated a case, before the Academy of Medicine, of a young man, æt. 25, who was suddenly seized with abdominal pain in the night-time; the following day he arose as usual, but his sufferings became so great that he had to return to bed, and feeling worse he was admitted to the hospital, with a temperature of 102° and considerable pain in the right iliac fossa. Laparotomy was immediately practised, and the appendix found to be the seat of gangrene. The organ was resected, and a small abscess discovered behind the cæcum was drained. In spite of the operation, the patient never rallied. At the autopsy no signs of peritonitis were discovered, but the kidneys were the seat of acute nephritis of toxic origin apparently. This fact would lead us to suppose that appendicitis should be attributed to intoxication rather than infection. Consequently such cases should be operated immediately, otherwise the patient would be exposed to the gravest danger.

It was said, continued the speaker, that operations *à froid* gave superior results to operations *à chaud;* the fact was true, but the question should be considered from another point of view. In order that a patient be operated *a froid*, he must naturally have survived the acute stage of his appendicitis, and that happy result is not always certain to take place. For him he advised the operation to be performed on the third day, at the latest, after the first symptoms of the affection.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, July 26th, 1902.

Hæmoglobinæmia, Hæmoglobinuria and Hæmocytolysis.

At the "Gesellschaft für Innere Medizin" Hammerschlag showed preparations of blood taken from a patient who had suffered from erosion of the pancreas following gastric ulcer, ultimately producing hæmoglobinæmia, hæmoglobinuria and hæmocytolysis.

The patient was a female, æt. 36, who, suffered from ulcus ventriculi with secondary ectasia of the organ. After a long stay in hospital, hoping that careful supervision would soon restore the morbid condition to a healthy state, she was suddenly attacked with severe hæmatemesis, succeeded on the following day by an alarming collapse. In two days later the hæmorrhage was repeated. About twenty hours after the collapse hæmoglobinuria was observed for the first time, and two days later she died.

The examination of the blood showed large quantities of blood corpuscles with yellow annular margins named by Taube "Blutkörperschatten," indicative of hæmocytolysis. In addition to these there were numerous nucleated red blood corpuscles both normal and megaloblasts; relative increase of leucocytes, nucleated with neutrophile granulation. This led on the first glance to a diagnosis of leucocytosis, but the presence of the yellow annular corpuscles and the absence of any eosinophile cells were against any such conclusion. It is worthy of note that there was every appearance of rapid blood regeneration.

The post-mortem revealed an old contracted cicatrix, causing a stenosis of the pylorus, with a deep ulcer on the posterior wall of the stomach, which had eaten into the pancreas and caused a good deal of erosion, which was the probable cause of the hæmocytolysis, hæmoglobinuria and hæmoglobinæmia. In consideration of the interest in the poietic function of this organ, Klein tested its hæmolytic power in the laboratory; the extract was powerfully hæmolytic.

Kaufmann said that he recently had a somewhat similar case come under his notice with the hæmorrhagic diathesis and icterus.

The patient, a female, æt. 22, who, according to the history, had suffered the previous years from some affection of the stomach, associated with severe pain after food, which disappeared after three weeks' treatment on milk diet alone. From this recovery she seems to have been in good health, performing her daily duty till fourteen days before admission to hospital, when she was complaining of rheumatic pains in the upper and lower extremities. A week later pain commenced in the stomach, slight at first, but gradually increased in intensity, accompanied with a deep yellow colouring of the skin a few days before admission. It came out later that the patient had had bloody stools and vomiting, as well as bleeding from extremities. On her admission she was icteric, highly anæmic, but free from all fever. On the upper and lower extremities there were large hæmorrhagic patches, some of which were as broad as the palm of the hand.

The liver was greatly enlarged, but not painful to pressure; in the epigastrium a tumour covering the area of a gulden, flat, and lying over the aorta. All the other organs were healthy. The hæmorrhage seemed to be due to a secondary anæmia of a severe nature. A few days later blood began to come from the genitals, and ceased in the digestive tract under the free use of gelatin. On a rise of temperature commencing the red blood corpuscles fell to 1,300,000 with 15 per cent. of hæmoglobin, and finally the patient died on April 28th.

During the illness Professor Mannaberg suggested the cause to be carcinoma of the pancreas, which was confirmed at the post-mortem. A large ulcer in the stomach had perforated the pancreas, where cancer was found, which accounted for the hæmorrhagic diathesis. The compression of the ductus choledochus through the extension of the carcinoma and infiltration was the evident cause of the icterus.

Anæmia Recurrens.

Breuer next showed a case of recurrent anæmia of a severe type. The patient was now æt. 42, and visited Nothnagel's clinic in 1898 for the first time. In 1888 she seems to have suffered from fever of a recurring nature, as she relates two attacks of fever in the same day, probably malaria. From 1896 to her admission into hospital she seems to have been pale in complexion, but no real pain or other disturbance till the week before admission, when she was seized with severe palpitation, sickness, vertigo, weakness, and extreme paleness.

On admission the anæmia was severe:—Hæmoglobin, 20; red blood corpuscles, 2,300,000; white corpuscles, 4,900; microscope showed alterations in the erythrocites with individual normo-blasts. There were present systolic murmur, hard spleen two finger breadths below the margin of the ribs. Nothing particular about stool or urine—no parasites. During her six weeks residence she was treated with iron and arsenic, which appeared to be successful from the rapid improvement that set in after the third week. On January 5th she was dismissed, when the hæmoglobin was found to be 83 per cent.; red corpuscles, 5,000,000; and white, 7,000. During the next 3½ years she had seven similar attacks occurring without any attributable cause. The first of these occurred about half a year after leaving hospital, when she returned on the first symptom appearing, remained ten weeks, and was again dismissed.

The cause of this anæmia was somewhat enigmatical, but presumptively, pernicious in character. The blood examination since the second admission into hospital has had the following peculiar characteristic—on leaving a decided oligocythæmia or high colour index; on reception the red blood corpuscles were marked by poikilocytosis, with a large number of microcytes and a moderate number of megaloblasts. The improvement progressed regularly without any crisis, although always found to be 100 per cm. in hæmoglobin and 4,400,000 macrocytes were constantly present. The white corpuscles contained 50 per cent. of lymphocytes. At present the patient was recovering from an attack, but whether to state the case as one of pernicious anæmia as the primary cause of these relapses was very difficult to determine, as it was one of those anomalous cases lying on the border line.

Banti's Disease.

Breuer brought before the notice of the Society another case of a young woman, æt. 23, who up till two years ago was perfectly healthy, but after this period began to gradually enlarge over the abdomen.

Neither malaria nor syphilis had ever been present. A year ago the enlargement was diagnosed as a splenic tumour, whereupon arsenic was freely administered for a few months without success. More recently she complained of extreme weakness and pain in the back associated with palpitation.

On her reception into hospital a hard splenic tumour was easily palpated over the symphysis pubis in the middle line. The liver was slightly enlarged but smooth, with slight œdema of abdomen. No glandular swellings; accidental systolic murmur; lungs, normal. The blood had 58 per cent. of hæmoglobin, 2,800,000 red corpuscles, and 1,800 white corpuscles, or a proportion of 1,600 to 1. Beyond this leucocytosis there was a slight relative lymphocytosis. In the urine was found a large amount of urobilin and gall-colouring matter. There were temporary attacks of icterus in hospital, but under arsenic treatment the colour improved, but the tumour remained the same although the blood changed:—Hæmoglobin 72 per cent., red corpuscles 4,000,000, white 1,270, or proportion of 3,100 to 1. The complex symptoms with successive leucohemia pointed to an advanced form of Banti's disease.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Wound of the Subclavian Artery.—Mr. Carless operated late one night on a woman, æt. about 30, who had been admitted a few hours before with a revolver wound on the left side of the chest. She had been quarrelling with her husband, a Russian Pole, and he, holding the revolver under his hand so that it pointed upwards, shot her in the left side. This occurred about three o'clock. Severe hæmorrhage ensued, but this was apparently controlled after a time. When seen at half-past nine on the same evening Mr. Carless found her somewhat blanched; there was no pulse at the left wrist, and a pulsating swelling was observed occupying the left infra-clavicular fossa; this swelling was about three and a-half inches in diameter, and the tissues near it were somewhat ecchymosed. The aperture of entrance was about two centimetres in diameter, and the tissues around were lacerated, it was situated about two inches to the left and a little above the left nipple, so that it lay close to the anterior axillary fold. The passage of a probe along the wound was checked by the soft tissues. The patient was anæsthetised, and it was then found that the bullet had passed upwards and inwards, towards the middle of the clavicle. A crescentic incision was made, passing through the wound and extending from the inner end of the clavicle nearly to the acromion process. The flap thus marked out was turned up, and it was then found that the bullet had passed deeply between the pectoralis major and the deltoid muscles. This space was opened up, and on retracting and partially dividing the pectoralis major a tense bluish black swelling came into view. On passing the finger deeply so as to define the structures, this swelling burst, and a forcible jet of bright arterial blood was shot out over the apron worn by the operator. This hæmorrhage was at once controlled by an assistant who was waiting to compress the subclavian artery above the clavicle. The parts were carefully separated, the pectoralis minor being drawn outwards, and various bleeding points, probably branches of the acromio-thoracic axis, secured. The dissection was extremely difficult, owing to the tissues being infiltrated with blood, but finally it was found that the bleeding came from the subclavian trunk just below the clavicle as the artery lay on the first rib. A small portion of the inferior wall, half an inch in length, had been shot away. The aneurysm needle was passed under the vessel, which was tied above and below the lesion. On releasing the subclavian trunk above the clavicle it was found that the hæmostasis was complete. The axillary vein came into view during the dissection, and was seen to be very much distended. The patient had lost a considerable amount of blood during this procedure, as the pressure on the subclavian artery had to be relaxed every now and then "to give the surgeon a show" as to where the bleeding came from; it was therefore considered inadvisable to make any attempt to find the bullet. A drainage tube was introduced leading down to the site of ligature, and the wound was rapidly stitched up. During this procedure two pints of warm salt solution (ʒ to a pint) were slowly injected high up the rectum through a catheter, and as soon as the operation was over the median basilic vein in the right arm was opened and a pint or more of the same fluid at a temperature of about 108° was introduced. The wound was dressed and the patient put back to bed, with instructions to have the left arm wrapped up in antiseptic wool and slightly raised. Mr. Carless remarked on the unusual character of this case. It would hardly seem possible, he said, for a patient with a wound of the subclavian artery which was not tied or controlled to live for six hours; he pointed out that had the artery been wounded above the clavicle through a direct passage to the surface the woman would certainly have bled to death. As it was she lost so much blood that the doctor who first saw her had given her but a few minutes to live, and had proceeded to take her dying declaration. The immediate hæmorrhage ceased partly as a result of the diminished heart's action, but mainly as a result of the tension of the tissues around the artery. Behind was the chest wall; above the clavicle and subclavius muscle; externally the coracoid process and pectoralis minor, and in front the costo-coracoid membrane, through which only a small opening had been made by the bullet, so that the escape of the blood was checked after a time. The pulsating swelling which was felt beneath the clavicle before the operation was evidently caused by the stretching of this structure beneath the pectoralis major, and as soon as it was opened up by the finger the bleeding recommenced. Mr. Carless commented on the fact that these operations are frequently difficult and prolonged. It was easy to say "tie the bleeding point," but it was quite a different matter to do it. He also pointed out the necessity for a double ligature in this instance, as otherwise bleeding would recur from the lower end as soon as the collateral circulation was established.

It is interesting to report that the patient has done well; there has been no recurrence of the bleeding and no gangrene of the arm; the patient complains of pain in the arm above the clavicle, which is probably due to the presence of the bullet irritating the brachial plexus, which, however, it does not appear to have seriously damaged as there is no actual evidence of nerve lesion. Later on the bullet will be looked for with the X-rays and, if necessary, removed.

NORTH-WEST LONDON HOSPITAL.

Short Circuiting the Intestine for Chronic Dysentery.—Mr. **Mayo Collier** operated on a man, æt. 31, for the last seven years the subject of chronic and apparently incurable dysentery. The condition of the patient being apparently hopeless, and drugs failing to give relief, Mr. Mayo Collier advised that the ileum near the caput cæcum coli should be brought to the surface and used as a temporary anus until the colon should heal, thus short-circuiting the alimentary canal. Mr. Collier made an incision in the median line between the umbilicus and the pubes of about four inches in extent. The abdominal cavity was opened and the colon examined as far as practicable. Nothing definite was made out from this examination, A loop of the ileum about six inches from the valve was brought into the wound and supported by a glass rod being passed close to its mesenteric attachment. The bowel was then attached to the four corners of the wound by four silk stitches. The extent of the original opening was curtailed by deep and superficial sutures at the upper and lower extremities of the wound. Mr. Collier said he intended opening the piece of bowel so fixed on the fourth day and washing out the colon daily so as to assist its healing. By these means he thought the dysentery will probably abate and disappear. Subsequently the loop of bowel will be detached from the abdominal opening by an oval incision, the edges of the opening in the bowel pared and closed by gut sutures, and the loop replaced in the abdominal cavity.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 30, 1902.

PAID SPECIALISTS IN DISPENSARY PRACTICE.

A year ago the attention of the medical profession in the United Kingdom was focussed upon Birmingham, where a curious drama was being enacted; a private organisation having convinced themselves that it was desirable to provide at half fees general and special consultation for persons unable to pay full consultation fees. This Specialist Consultative Institute, as it was named, advertised broadcast and appointed a consultant. The latter gentleman, however, speedily found himself subject to the disciplinary hand of the General Medical Council by reason of the general advertisement above mentioned. Had there been no advertising it seems more than likely that the proceedings of the Consultative Institute would have met with no effectual check. However, after a sharp reproof and warning from the General Medical Council, the medical man in question determined to sever his connection with the Institute rather than sacrifice his diploma. While this dispute was in progress feeling ran high in the medical profession not only in Birmingham but also throughout the kingdom. The withdrawal of the "Consultant" and the collapse of the Institute were hailed with general satisfaction, for it was felt that the right of the profession to regulate its affair in accordance with certain ancient and honourable traditions had been amply vindicated in the teeth of a strenuous and powerful attack. The echoes awakened by the incident, however, have not yet died away. It is not too much to say that the cause of professional organisation has been greatly strengthened thereby. The latest outcome appears to be a scheme which proposes to attach a modified consultative staff to the General Dispensary of Birmingham, a medical charity that carries out a vast amount of good work among the poorer classes. It is now proposed to attach four consulting surgeons and four consulting physicians to the dispensary, together with two gynæcologists and one ophthalmic surgeon, all of them to be paid by fees. We shall watch the progress of this new departure, assuming it to be adopted at the annual meeting of the charity in February, 1903, with considerable interest. Meanwhile, the proposal to extend the principle of payment for services to the consultant staff of medical charities demands the interested attention of the profession, to say nothing of the philanthropic public. Turning to the general question of the services of medical men to medical charities we have little hesitation in expressing an emphatic opinion that an honorarium should in all cases be granted in return for such services. Where no such recognition is accorded, the hardship falls with peculiar severity upon the younger members of the staff, that is to say, precisely upon those who are least able to give their services gratuitously. The senior who has fought his way to position and fortune has no need of any honorarium from the funds of his hospital or infirmary. To ask the younger men of narrow incomes, however, to discharge those highly-skilled duties whereby the work of a medical charity is carried on, is, in our opinion, a vicious and inhuman system. In a great many instances, in London as well as in the provinces, the payment of a small honorarium, say, of fifty or a hundred guineas per annum, has been the rule to all members of the consultant medical and surgical staff. With all the huge resources at the command of the medical charities of the United Kingdom there would be little difficulty in meeting the small additional tax upon income. As things stand the noble cause of charity is administered largely at the cost of a band of professional men who can ill afford to give their services gratuitously. If it be right to recompense the house surgeon and other residents for their services it surely cannot be wrong to recompense the consultants in a similar way. A better organisation of the medical profession would enable it to urge these views upon lay executive committees and upon the public generally.

CRIMINAL DEGENERACY.

The year 1859, which initiated so many political and scientific revolutions, may be said to have given birth to the modern science of criminology. It was during the seething activity of the Italian wars, and the social, religious and political convulsions which led to the formation of a young "United Italy," that Cesare Lombroso commenced his epoch-making investigations in the department of the "study of mankind," with which his name is now connected for all time. It is one remarkable instance of the applicability of the fruits of his laborious investigations to the protection of human life at the opening of this democratic twentieth century of ours, that he diagnosticated, and predicted the future development of, the criminal tendencies of Gaetano Bresci, who afterwards murdered the King of Italy. This fact, with a vast number of other interesting ones, have been published in a medico-psychological study of the subject of political assassination which appeared in a recent number of the *Philadelphia Medical Journal* from the able pen of Professor Charles K. Mills. Inspired by the recent assassination of the President of the United States, Professor Mills has collected and analysed the facts recorded in connection with the fifteen most prominent political assassinations—beginning with that of Henry III. of France, and ending with that of President McKinley. His analysis is extremely subtle, although some of us may think that there are hardly sufficient data from which to draw so definite conclusions in some of the cases. But even in these his processes of investigation are instructive and always suggestive. He arranges his political assassins under four heads: *sane, insane, degenerate but not insane,* and *degenerate and insane.* Booth, the assassin of President Lincoln, was sane, but, an alcoholic degenerate. Charlotte Corday, the assassin of Marat, was another degenerate. So was Cesario Santo, the assassin of President Carnot of France. So, also, was Michel Golli, the assassin of Señor Canovas, the Spanish Premier. The assassin of the Empress of Austria was a "degenerate with criminal instincts." The assassin of King Humbert of Italy, to whom we have already referred, was a degenerate of moody temperament. Czolgosz was a degenerate, but probably sane. It is an interesting fact that Darwin published the results of his special investigations in the year in which Lombroso commenced his. The "Origin of Species" convulsed the scientific world in the year 1859, the thrilling year in which Garibaldi rose up to construct a United Italy, and Lombroso sat down to make anthropological measurements and moral dissections of criminal humanity. There can be no doubt that the results placed before the scientific world by our famous fellow-countryman suggested an outline, at least, of the life-work of the Italian anthropologist. The views and the results arrived at, as well as the lines of reasoning followed, have in the cases of both these remarkable men received the most scathing criticism from the hands of their scientific opponents. Yet even in the cases where the data of these great students of the mysteries of Nature are least perfect, or their lines of reasoning least consequential, there can be no question that their collected materials are worthy of the most careful attention; while the earnestness and persistency of purpose displayed by each cannot be denied by even the most bigoted opponent of either. Still it must be lamented that the dissipation of ignorance and the accumulation of scientific facts have by no means increased the moral self-restraint and the instinctive benevolence in the proportion which had been foretold by some earnest philosophers and progressive politicians. We now hear sanguine hopes expressed nearly every day that we are rapidly approaching a period when bacteria will be extinct, and disease a matter of past history. Let us express the hope that the attainment of this desirable consummation will be in a time when the mental and moral aberrations of man shall also have ceased to be a matter of personal experience.

Notes on Current Topics.

Cholera and Plague in Egypt.

THE news from Cairo is most serious as regards the outbreak of cholera. On the 26th there were no less than 95 fresh cases, and 93 deaths, while other towns are affected. On the 27th 52 fresh cases were reported, among them being several Europeans. Since July 15th there have been in all 469 cases, with 382 deaths. This represents a most serious state of affairs, especially when taken in conjunction with the invasion of plague. The total number of cases of plague throughout Egypt is 19. Of these 16 are in Alexandria and 7 are Europeans. Since April 7th there have been 269 cases of plague, with 152 deaths. The state of affairs arising from this dual invasion clearly concerns the safety of the whole of Europe, and may even give rise to widespread alarm and anxiety, especially in countries where practical sanitation does not reach a high standard of excellence.

The Woodbridge Treatment of Typhoid Fever.

IN the April number of the *Indian Med. Gaz.*, Major A. G. Hendley, I.M.S., has given his personal experiences of three cases of typhoid fever treated by the "Woodbridge method." The results obtained were decidedly favourable, and give just grounds for the demand that the claims which have been advanced for this method of treatment by its originator, Dr. Woodbridge, and borne out by reports in American professional literature, should receive the fullest attention from the medical world. The plague of enteric still remains among the most terrible physical scourges of India and South Africa; and yet Major Hendley tells us that he had been "unable to find, in back numbers of the *Indian Med. Gaz.*, any recorded results of treatment of typhoid fever by this method," and also adds that "none of my medical friends could give me personal experience of it." The claim of Dr. Woodbridge is, that his treatment, "if commenced early enough, will abort, shorten and greatly modify cases; that there is no tendency to relapse, no unfavourable complications; and that the bad effect of prolonged stimulation is done away with." The treatment is a general or intestinal eliminative one: it consists in giving very frequently—"every fifteen minutes during wakeful portion of first forty-eight hours"—small doses of varying formulæ of podophyllum resin and calomel combined with such antiseptics as guaiacol carbonate, menthol, eucalyptol and thymol; the indications being to produce free evacuations as early as possible, and by subsequently varying doses to keep the bowels regular. Ptyalism is avoided by discontinuing treatment on the fourth or fifth day, for one or two days; during which interval drachm doses of saturated chlorate of potash solution are given every three hours. Major Hendley's report is an eminently favourable one, and we should be very glad to hear of the results of the investigations of others regarding so important a therapeutic problem.

Murphy's Button.

An extremely interesting report of a post-mortem examination of the body of a patient who had, nearly seven years before, been the subject of a successful operation of gastro-jejunostomy—performed for the relief of the symptoms produced by enormous dilatation of the stomach—has recently been given by A. H. Cordier, M.D., Professor of Abdominal Surgery, University Medical College (Kansas City, Mo.). Professor Cordier made the "anastomosis" between the anterior wall of the stomach, about four inches from the pylorus, and a coil of the jejunum, fifteen to eighteen inches below that orifice. Murphy's button was used. At the autopsy, which the operator made nearly seven years afterwards, he found complete obstruction of the pylorus; the size of the stomach had been restored to the normal standard, and its coats were quite healthy; the loop of intestine between the pylorus and the anastomotic orifice had undergone atrophy from disuse. No traces of peritoneal adhesion existed around the site of the operation. The pyloric obstruction—which seemed to be valvular—prevented the contents of the stomach passing into the upper loop of intestine; it also prevented the regurgitation of bile into the stomach. Air or water could not be made to pass from the stomach through the pyloric orifice, till the stomach and the lower segment of the bowel had been fully distended. But the unique feature in this interesting history is that the Murphy's button which had been employed at the operation was found lying in the stomach, where its seven years' sojourn had never given rise to a single untoward symptom! One end of the button was very much corroded [digested?].

Holidays and Health.

The approach of the holiday season should remind medical men, as well as their patients, of the necessity for the observation of periodic times of rest and relaxation. There is no calling in life whose followers more surely require the religious observance of what days can be conveniently set apart for the vacuous purpose of performing no manner of labour therein. The continuously increasing hurry and worry of the twentieth century is infallibly adding to the roll of its neurasthenic victims—in approximately geometrical progression. In the medical profession there exists a unique combination of physical exposure with intellectual strain and mental anxiety. In a recent number of *The Journal of the American Medical Association* Dr. James H. McBride discusses "Some Points in the Management of the Neurasthenic," and makes some most instructive observations, followed by very excellent advice. He points out that "the possession of certain mental qualities in a high degree may render one more liable to brain exhaustion. I have known people who, though mentally and physically vigorous, became the subjects of brain exhaustion from the fact of their having an unusual ability for close mental application so profound and intense that they would go beyond their limits without knowing it." This fact is as surely true as it is usually unrecognised. And when such persons are simultaneously exposed to strains of physical exertion, stresses of wind and weather, and the harassing endeavours to please an implacable public, how deplorable the result is likely to be! Perhaps the best approach to a specific prophylactic in all such cases will be found in the careful obedience of the commandment: "Remember the holiday to keep it holy."

The Gulf Stream Myth.

The progressive march of science necessarily includes an iconoclastic crusade, and in this unprecedentedly active age of scientific investigation hardly any theory can be accounted safe from attack or unexpected revelation. One of the recent theoric victims which appears to be hopelessly doomed to wither under exposure to the penetrating glare of the search light of twentieth century science is the now rebaptised "Gulf Stream Myth." When the late M. de Lesseps was monarch of the engineering world, and planned the section of the Isthmus of Panama for the purpose of uniting the Atlantic and Pacific oceans, and the tunnelling of the Atlas range for the purpose of converting the scorching, sandy Sahara desert into a cool and smiling inland sea, the meteorological department of the scientific world was, in each case, seriously exercised by contemplation of the cataclysmic changes in the balancing of our globe on its axis; and in the distribution of surface temperature, which must inevitably follow the completion of either of these great undertakings. Since that stirring time speculation has simmered down to the old dead level; as it has been found that the Sahara desert, with the exception of two insignificant potholes, is a ridged plateau, placed well above sea-level; and the Gulf Stream is but a mythical agent, so far as influence upon the climate of the British Isles and the West Coast of Europe in general is concerned. And thus we find that the panic fear of a new glacial era for the British Isles to follow section of the Isthmus of Panama—was correspondingly groundless. Mr. H. M. Watts deals with the subject in the June number of *Scribner's Magazine*, and shows conclusively that the influence of the Gulf Stream on the climate of our shores is purely imaginary and mythical, and that the mid-Atlantic anticyclone is the agent which really determines the mildness of our temperature. The necessarily variable movements of this agent furnish, from time to time, "January thaws," "anticipations of spring," "early summers," "heat waves," "Indian summers" and "green Christmasses." The existence of the Gulf Stream itself—such as it is—depends on the aerial currents. So dies another meteorological myth!

The Race for Life.

The most "progressive" town of the most "progressive" community in our twentieth century world has recently been winning a new distinction as the most prominent "suicide centre." Chicago registered thirteen cases of suicide for the week ending May 10th, 1902, and fourteen for the following week. This record surpasses that of any other large city in the world, and represents a proportion to total population more than three times as great as that of the United States at large—which was already a notable one. The scientific and official authorities of Chicago attribute the gruesome prevalence of suicide to post-influenzal depression of mind; but, as a contemporary points out, the same cause has not in other places led to a corresponding result. The fact undoubtedly is that the race for life is far too fast in the rapidly growing midland capital of the great Western Republic. And we think it our duty to point out the *moral*—that the most advanced democracy has as completely failed to establish happiness and contentment among men as ever did the cast-iron despotisms of Oriental type, or even the ruthless autocracies of savage and cannibalistic tribes in Africa and Australasia. It is rather difficult for a disinterested observer, who sets himself to discuss the movements of the crowd from a "Jack Horner" position, to satisfy himself why our trans-Atlantic cousins so deliberately set out at the start of life with the transparent intention of racing one another to death, and of depriving one another, during the greater part of the course, of almost all chances of enjoyment of the very many comforts which the immense advances of recent years in physical and mechanical methods have placed within the reach of all. We would suggest that instead of looking *only* forwards towards the goal of the coveted "success," Chicago citizens—as a body—should waste some portion of their time in looking to either side, and even backwards.

Colour Vision of Egyptian Natives.

The subject of "The Colour Vision of the Natives of Upper Egypt" is dealt with in an interesting and instructive communication presented to the Anthropological Institute of Great Britain and Ireland, and published in the last volume of their *Journal*. Mr. Rivers took up the thread of an investigation which had been previously started by Mr. D. Randall-MacIver, and employed the same seven test-wools which he had used in his investigations in Torres Straits and elsewhere—bright red, bright green, Holmgren's pink test, Holmgren's pale green test, yellow, blue and violet, usually in the order named. The results showed that the fellâhin of Upper Egypt resembled the English in being less sensitive to red than to yellow. In this respect they differed from the Murray Islanders, but agreed with the latter in their "marked insensitiveneess to blue." Mr. Rivers observes that "the Egyptians seem to occupy an intermediate position between the Englishmen and the Papii, and resembling the former in one respect and the latter in another." He also notes that "the cases of marked insensitiveness to red (red-green blindness or red-green weakness) which occur in both England and Egypt were absent in Torres Straits." The existence of colour-blindness in both Egyptians and Englishmen appears to be accompanied by a certain degree of general insensitiveness to red as compared with Papuans. It is also a significant fact that the Murray Islanders had no native word for blue. The Egyptians had no *definite* term either; but there are two or more words which they applied indiscriminately to violet, blue, dark brown, and black. On the other hand pink and violet appear to be more readily matched by those inferior races than by Europeans. Each of these colours contains both red and blue, and are confused by individuals with weakness of the red-green sense. The *warm* tones, the *emotional* tints appeal most strongly to the savage sensorium. All readers are familiar with the oft-repeated judgment of the inexperienced blind man who compared scarlet to the sound of a trumpet. African explorers well know the value of flaring red and yellow items of apparel when preparing for a "palaver" with a native chief. Sir Joshua Reynolds mostly used these pigments. The old age of the nineteenth century carried civilisation across the spectrum to the bleached, æsthetic blue.

The Psychological Development of the Nation.

Much has recently been written, and still more has been said, respecting a change in the emotional attitude of the people, and alteration in the mental standpoint of the nation. It is certain that of recent years in certain sections of Society there has been a considerable improvement in the physical condition, and it is impossible to deny that evidences have not been wanting to show that some alteration has been slowly taking place in the psychological life of many of the community. The increasing congregation in cities, the incessant pursuit of pleasure, the freedom from restriction enjoyed by the young, the loosing of the bonds of parental control, the liberty claimed by females, and many other facts, have gone far in bringing about the psychological change. It cannot be denied that there is much in modern life tending to develop the neurotic. Neurologists are ever on the look out for fresh manifestation of the neurotic element. Neurosis now accounts for much of the ills which flesh is heir to, if many latter day "nerve specialists" are to be believed. And certainly alienists are constantly impressing upon us the depressing fact that mental instability is much on the increase, and that insanity is becoming alarmingly prevalent. It is true that to many an old-fashioned observer there are signs that many of the younger members of the community are lacking in restraint and manifest emotional display that is repugnant to the ancient British spirit. But when we consider the long period of stress and strain which has been borne by practically every family during the recent war, and estimate the disappointments and financial disasters brought down upon the people with tragic suddenness by the King's illness and the postponement of his Coronation, we have no hesitation in saying that the old spirit is still with us, and that psychological decadence has not robbed our people of those elements of patience, restraint and quiet perseverance which have built up a mighty empire.

Sentimentalism and Horses' Sun Bonnets.

Truly, in these humanitarian days it is not a little amusing to note how in many cases kindness is swallowed up in vapid unreasoning sentimentalism. There never was a more striking instance of this transformation than in the use of the sun bonnet for horses. It is true that horses die on hot days out in the sun, but it is equally true that they die on cold and wet days. In ninety-nine cases out of a hundred the poor brute dies of heart failure, induced by overwork. The majority of horses are overworked, both in speed, weight to be carried or drawn, and duration of hours of toil, to say nothing of their sufferings from hunger and thirst, the lash of the whip, the constant stoppages and restarting necessary in crowded traffic, and the torture of the bearing-rein. To put a sun bonnet on the head of this much-abused brute is a sheer mockery. There is no proof that any horse ever suffered from the effects of the sun's rays falling upon his head. Among the human race it is now a well-recognised fact that so-called "sunstroke" is due to a microbial invasion of the body; in other words, it is a kind of specific fever, and can be contracted in the shade. The Dumb Friends League, an excellent society, might husband its resources by declining to pander to the last fad of unreasoning sentiment which decks out the horses in the streets with millinery grotesque and unsuitable enough to gratify the soul of the most foolish of feminine leaders of fashion.

Post-Vaccinal Eruptions.

In a recent number of *The British Journal of Dermatology*, W. T. Freeman, M.D., F.R.C.S., has discussed the important subject of "Post-Vaccinal Eruptions," in a very interesting and instructive "Clinical Note." The first of his illustrative cases was that of a servant girl, aged 23. On the sixth day after vaccination nine shotty papules were found about the wrists and on the back of the hand on the left side. They were about to pass into the vesicular stage, and were found, two days later, to have become all vesicular or semi-pustular and umbilicated. They were all multilocular. They "dried up," after the fashion of ordinary vaccination vesicles and dark scabs formed, which fell off at about the end of three weeks. Dr. Freeman concludes that it was a case of generalised vaccinia. In another case, that of a lady teacher in a high-class school, an erythema commenced on the eighth day to spread from the inflammatory area around the vaccination pustules. It spread over the arm, and "the body generally." When examined, two days later, the whole body was covered with a multiform erythematous rash. "Here it deserved the term of Erythema papulatum, here that of E. tuberculatum, here the round patches and circles were those of E. annulare, and here and there segments of circles and wavy bands suggested E. gyratum." There were also present "one or two urticarial wheals, and a very occasional small bulla situated upon an erythematous base." There was moderate fever. The eruption cleared up in about a fortnight. Another, and more serious, case occurred in the person of a weakly male, aged 54, who became ill when the scabbing process was quite complete—at the end of the third week. The whole trunk was then red, and there were a few sudamina. Two days later the whole trunk was covered with a bullous eruption. The bullæ ranged from the size of a threepenny piece to an area somewhat larger than a five-shilling piece. Some were slightly hæmorrhagic. However, they all dried up, and the man was convalescent in a few weeks. There were some other cases—of a measly rash, and of an erythematous one. The record of such cases is instructive.

Diagnosis Puncture.

In these days of asepticism it is somewhat remarkable that the simple method of diagnosis by puncture with an exploring needle is not more extensively practised. The old way of exploring by a grooved needle was bad, inasmuch as it furnished a wound full of septic possibilities, but still it was better than nothing; Listerism, however, has changed all that, and the long fine needle of a carefully sterilised hypodermic syringe can be plunged fearlessly into almost any cavity in the body. Its chief use, perhaps, is in confirming a diagnosis of pleuritic effusion or of empyema of the chest. The careful medical man will never neglect the simple precaution of inserting his diagnosis needle before performing a paracentesis of the chest. As every surgeon knows, pus may often be loculated in the pleural cavity, and in that case may readily evade the probing incision of the surgeon, however cautiously directed. The puncture of a fine needle causes so little pain that there is no need, as a rule, even for a local anæsthetic. The only risk is that of breaking off the needle in the tissues, an accident sometimes caused by an abrupt movement on the part of the patient. If the operator be on his guard the risk of such an occurrence can be readily excluded.

The annual general meeting of the Brussels Medical Graduates' Association was held at the Trocádero on July 15th, when Dr. A. E. Snape was elected president.

Poor-law Patients and the Spread of Phthisis.

Although Hampstead is one of the healthiest and wealthiest districts of the Metropolis it is nevertheless saddled with a poor population and a workhouse. The resident medical officer of the district, if we remember aright, came into prominence some years ago as being the recipient of a microscopic salary. Hampstead is now in a quandary. The Board of Guardians has been advised to send the Poor-law phthisical patients out on the magnificent Heath, which, indeed, would be an ideal recreation ground for patients suffering from the particular malady in question. At a recent meeting, however, the Chairman pointed out the extreme danger of allowing these patients to go on the Heath, inasmuch as they gravitated to the public-houses. The medical officer favoured the proposal if patients carried expectoration bottles and were prevented from going to the public-houses. There the matter rests for the present. So far as the purity of the air is concerned the patients would be almost as well off in the grounds of the workhouse infirmary, and the safety of the public would be better guarded if they were kept within the lesser boundary. This sort of question in a more or less modified form is sure to crop up occasionally now that sanatoria for consumptives have been so generally established throughout the United Kingdom. From a preventive point of view there is little danger likely to arise from a consumptive patient straying at large over a heath, whereas on the other hand he becomes a distinct danger as a customer in a public-house.

What is "Introduction in the Sale of a Practice?"

An action recently tried by the Lord Chief Justice at the Manchester Assizes presents some points of interest to the medical profession. The claim was for £241 18s. 2d., the balance due on the sale of the practice of the late Dr. Kelty, of Blackpool, from whom the defendant, Dr. Carr, purchased the practice for the sum of £1,000. The action was raised by the executors of Dr. Kelty. The answer was a counter-claim by the defendant for damages for breach of agreement in non-introduction of the plaintiff to some of Dr. Kelty's patients, and for continuance of practice by Dr. Kelty contrary to a penalty clause. The latter part of the counter-claim appears to have been abandoned. With regard to the former, it appears that at the time of sale there were 253 patients on the ledger, but the purchaser alleged he was introduced to forty-six only, and that because they wanted medical assistance; at the end of six months, he further said, he was introduced to twenty-six other patients who were not on the ledger. On the other side the widow produced a list containing 156 names of persons who to her knowledge were introduced to Dr. Carr. With regard to a list of 140 persons whose names were taken from the ledger by Dr. Carr, and stated not to have been introduced to him, Mrs. Kelty explained that many were visitors, some were dead, and others had not been attended for a long time. The learned Judge expressed an opinion that Dr. Carr's counter-claim was an expression of irritation, and had not been proved. He therefore gave judgment in favour of the executors of the late Dr. Kelty for £241 and costs. The legal expenses of the dispute will naturally be very heavy.

Quicksilver—Re-quickened!

A remarkable example of recurrence to an old, and emphatically discredited, item of medical therapeusis is that which has recently been placed on record by Dr. J. McKean Harrison. This gentleman treated two cases of acute intestinal obstruction with *half-pound doses of quicksilver.* In each case laparotomy had been discussed; in one it was declined, and in the second, the octogenarian standing of the patient, and the exceptional severity of the symptoms, rendered all hope of its successful use untenable. In each case the administration of the ponderous metallic dose was followed, in due time, by amelioration of the symptoms, relief of the obstruction—as shown by the action of the bowels, and complete recovery. The introduction of this peculiarly ponderous agent produced no increase of the abdominal pain, and there was no attempt at the development of ptyalism. Reflection on these remarkable results makes one think that too many of the old remedies have been placed on the high shelf—and even forgotten there. We were not able to follow Dr. Harrison quite to his conclusion in the first of his cases, in which he had made a diagnosis of "volvulus," which he considers that the weight and fluidity of the quicksilver "must certainly have unravelled." In the former centuries, when quicksilver was the "regulation" treatment of intussusception, the theoretic explanation of its action was based on the mistaken idea that the telescoped segment of the gut always came from below; it was then, of course, dragged back by the weight. Surely the ways of quicksilver, therapeutic and other, have always been mysterious. Thomas Dover, the celebrated "quicksilver doctor," used to treat, successfully, cases of spasmodic asthma with *lb. wt.* doses of Hg.! Indeed, he cured, so he says, most acute diseases with this remedy. He made a special exception of gout, for which he invented his famous "Powder."

The Prevention of Consumption.

It has been fairly well impressed on the public by constant iteration that the prevention of tuberculosis is one of its primary duties. The chief difficulty now is to point out in what way the community should act to fulfil this duty, and, in particular, what are the functions of public health authorities. Several municipalities have devoted themselves more or less whole-heartedly to the anti-tuberculosis campaign, and in this, as in some other fields of sanitary work, Manchester seems to have taken a leading place. The initial step is the adoption of notification, and, although this is voluntary, every facility is given to induce medical men to notify their cases, and in addition sputum is examined gratuitously by the health authorities. Following on the notification of each case are endeavours to educate the patient and his friends as to the nature of the disease and its infectivity, and where possible disinfectant treatment of his surroundings is carried out, with subsequently a continued supervision. Thorough disinfection also follows when a death from phthisis, if the case has not been previously notified, is registered. In addition, important investigations are conducted as to the sources of infection, the circumstances influencing infection, and the habits of the patient and other predisposing causes. It is only by experiment that we can learn, and whether the Manchester scheme gives good results or not only time can tell, but none the less is great credit due to Dr. Niven for its origination and inception.

A Plague Spot in the Midst of Beauty.

ABOUT fifteen miles from the mouth of the estuary of the Shannon is the old town of Kilrush, a seaport and market town in the County of Clare, twenty-one miles from Ennis. In times past ships of war and lofty East Indiamen rode safely in the deep waters of its bay at all times of the tide. Nature has done much for the town, and philanthropists have not forgotten it. Erasmus Smith's Charity founded and supports a school there for 280 children. We need not tell of this further, our concern is with the present condition of this delightfully-situated town which (*Clare Journal*) is very bad as regards sanitation. Dr. Counihan has just stamped out an epidemic of typhoid fever in one of its back streets; and he makes the alarming, and we believe true, statement, that most of the houses are without any sanitary convenience whatever; and at their back runs an evil-smelling drain. All credit is due to Dr. Counihan for drawing attention to the utterly insanitary condition of the town. A town, which if it were kept tolerably clean would be one of the most attractive seaside resorts in the United Kingdom. In the centre of the wildest and most beautiful scenery in Ireland; mountain and wood and water, and ever and always the booming of the Atlantic surf waves as they surge against the cliffs of Clare. But all is made of none effect by the disregard of cleanliness of the people.

The Extern Examinerships at the Royal University, Ireland.

THE Extern Examinerships at the Royal University, appointment to which has been for so long a time delayed, have at last been filled, as will be found in our columns. The delay which occurred in this matter was principally due to the differences of opinion among the members of the Senate as to what should constitute an "extern examiner." As our readers know, it was desired by one party that medical men practising in Ireland should be ineligible, while another party considered such a proposal unfair to the Irish members of the profession. It would appear from the result of the election that a compromise has been arrived at on this important point, as two of the examiners are Irishmen and two reside in Great Britain. We trust that the appointments which have been made will aid in maintaining the standard of the Royal University examinations. We regret that the Senate did not see fit to appoint Irishmen in every case, but presumably where so keen a conflict of opinion existed some such form of compromise as that which has occurred was bound to take place.

The Gradual Failure of our Carbonic Acid Gas Supply.

THE great tendency to levelling-down, which so eminently characterises this scientific and disillusionising age, is displayed throughout the whole of the physical universe, as significantly and emphatically as it is in the social and intellectual arrangements on the surface of our own planet. Lord Kelvin demonstrated, years ago, that the temperature of our solar system was in the way of progression towards the hopeless depths of the absolute zero. The present state of the moon furnishes an instructive object-lesson of advanced progress in that direction; its physical condition was compared by the late Dr. Samuel Haughton to that of an over-boiled potato. Our own globe is surely, if slowly, cooling down to a corresponding condition, so that recent volcanic activities have at least the consoling feature that they show that the end is not to come in our time. It was first pointed out by Schlosing that the supply of CO_2 in our atmosphere was chiefly derived from volcanic craters and springs—that the proportion derived from animal life was comparatively insignificant. And, as volcanic activity is undoubtedly diminishing on our globe—Krakatoa and St. Pierre notwithstanding—the future failure of CO_2 will form one of the prognostic symptoms of the approaching abolition of life on our planet.

THE Annual Congress of the Royal Institute of Public Health meets at Exeter from August 20th to 27th.

THE annual shorthand examination conducted by the Society of Medical Phonographers will be held in May, 1903.

THE Nineteenth Congress of the Sanitary Institute is to be held in Manchester from September 9th to September 13th.

THE death is announced of Surgeon-General Graham Auchinleck. He joined the Army Medical Department in 1848, and was in active service during the Burmese War of 1852, and in 1857 he was stationed at Mean Meer, when the Sepoys revolted, on which occasion he assisted at the disarming of them by the 81st Foot.

WE regret to learn that Surgeon-General Ringer, of Cheltenham, was knocked down by a motor-car on

Friday, sustaining a nasty cut on the forehead, as well as injury to the leg.

The King has been pleased to appoint Sir Frederick Treves, Bart, K.C.V.O., C.B., F.R.C.S., one of His Majesty's Honorary Serjeant Surgeons, to be a Serjeant Surgeon-in-Ordinary to his Majesty.

Lord Lister, like his other medical and surgical colleagues in attendance on the King during his recent critical illness, has undergone a good deal of anxiety. He has gone to Buxton to recuperate.

Among the Welshmen specially mentioned by Lord Kitchener in his latest dispatch is Civil-Surgeon R. F. Williams. He is a native of Talgarth, Breconshire, and was educated at Gonville and Caius College and the London Hospital.

DEATH FROM SULPHONAL POISONING.

To the Editor of The Medical Press and Circular.

Sir,—I should like to call attention through your columns to a fatal case of sulphonal poisoning which recently came within my experience, and which provides a further illustration of the danger of the self-administration of narcotics and other dangerous drugs by persons without medical knowledge. Sulphonal has the reputation of being a safe and harmless soporific, and for this reason it is largely used by members of the public. It can, moreover, be obtained with the utmost facility, as its sale is not governed by the restrictions which are imposed in the case of many poisonous drugs. Yet it is really a delusion to suppose that sulphonal can be safely taken unless considerable caution is exercised. Its action is decidedly uncertain, often varying to a somewhat remarkable extent in the case of different individuals. Thus, while it is stated that as many as 1,400 grains have been taken without fatal results, as small a dose as 30 grains has been known to produce serious symptoms. It therefore seems clear that this is a drug which should be used only on the advice of, and in the quantities prescribed by, a medical man, and it appears to me that the question of imposing some restrictions on its sale to the public might well be seriously considered.

In the case of fatal sulphonal poisoning to which I have referred, I was summoned to attend a man somewhat over forty years old, who had been found in an unconscious condition in bed. The pathognomonic symptoms which I remarked on being called in at 6.15 a.m. were as follows:—Moist stridor, resembling the death rattles, (which I heard before entering the room), deep coma, pupils contracted and insensible, pulse strong (80 per minute), heart acting well (no murmurs), respiration very slow (about 8 to the minute); at 8 a.m. it dropped to 4 to the minute. The face was dusky, the lips and tongue quite black, and the front of the thorax was also cyanosed. He had passed no urine since 7 p.m. the previous evening, and the bladder seemed empty. I was informed by the wife that her husband was in the habit of taking sulphonal for insomnia, measuring it out roughly in his hand, and, as the symptoms appeared to me to be entirely consistent with poisoning due to an overdose of this drug, I treated my patient in accordance with this supposition. He, however, died in the course of about five hours, without recovering consciousness. In the meantime another medical man had been called in, and he was unable to fully concur in my diagnosis, as he considered the man's condition might be due to a cerebral lesion. In this view, however, I could not coincide, as not only did the symptoms point, in my judgment, to sulphonal poisoning, but there was also an absence of some of the usual indications of cerebral lesion. Thus the breathing was nasal, there were no signs of inflation of the lips, and the appearance of the face and the character of the pulse negatived apoplexy. Under the circumstances, a post-mortem was naturally held, and the results made it fairly certain that sulphonal poisoning was the cause of death. The theory that a cerebral lesion had taken place was negatived by the fact that the brain and membranes were intact, although severely congested. The lungs and viscera were also much congested, and the hands were firmly flexed, the thumbs being turned inwards. Although death had taken place within thirty hours, there were already marked post-mortem changes, such as extensive perforation and ulcerations of the stomach. It may also be mentioned that, on the jugular vein being severed, a considerable quantity of gas bubbled up, and that a number of blebs, caused by gas, were found on the surface of the liver. The bladder contained about one ounce of urine of a pale straw colour, which gave a slight deposit on boiling with acetic acid, but none with picric acid. This case thus supports Garrod's opinion (*Journ. of Path. and Bact.*, 1892, Vol. I., ch. 2) that hæmatoporphyrin is not always produced by sulphonal poisoning.

It will be seen from what has been said that, not only is sulphonal a very dangerous drug in unskilled hands, but also that the symptoms produced by an overdose are sufficiently obscure to allow of the possibility of serious error as to the cause of death. For both these reasons, it seems to me desirable that all that is possible should be done to discourage the public from dosing themselves with sulphonal under the delusion that they are employing a drug of a comparatively innocuous nature.

I may, perhaps, add that the severe congestion which was discovered at the post-mortem, suggested to my mind, that bleeding might possibly be a desirable form of treatment in cases of sulphonal poisoning.

I am, Sir, yours truly,
James Hamilton.

60, Sydney Street, Chelsea, July 24th, 1902.

APPENDICITIS OR LOCAL PERITONITIS WITH OBSTRUCTION.

To the Editor of The Medical Press and Circular.

Sir,—The marvellous feats of surgery recently may well excite wonder. It should be of interest to remark that the symptoms which present themselves to the practitioner are the same whether the obstruction and peritonitis are due to intussusception, torsion, infarction, constriction by band of lymph, adhesion of opposing or adjacent parts with intestine, to tumour or to abscess, blocking the channel of the intestine. The history and the signs serving to differentiate, there will be in all cases pain at navel and in right groin, obstruction of the bowels, vomiting, meteorism, high temperature, and then collapse. If the condition be due to tumour or abscess, the history and appearance will indicate the cause. The writer in 1871, with Surgeon-Major Nolan, in the case of a Sepoy at Hyderabad, after trying the usual remedies to remove the inaction of the bowels and to abate the peritonitis, tapped the intestine with great relief to the patient, and afterwards on opening the abdomen, found that there was no exudation or inflammation from the puncture, and concluded that if an abdominal section had been done ere gangrene of the gut, the patient might have a chance. The cause was torsion with adhesion and constriction by bands of lymph. The writer advocated abdominal section as soon as medical treatment failed and before mortification and collapse would have set in. The writer brought abdominal section as a remedy for obstruction and peritonitis before the meeting of the British Medical Association in Dublin over a dozen years ago, and was fully endorsed by the late Mr. Lawson Tait, of Birmingham, but the writer insisted that tapping should be done early, especially if there were a history of abscess or circumscribed dropsy—watery tumour or otherwise—that if delay were made until gangrene of intestine pressed upon had set, there would be no alternative except an artificial anus with a physical and physiological history important and adverse. Local peritonitis may be cured by fomentations and mercury with opium, and leeches should not be despised, but if suppuration has set in the abscess should be tapped at once with trocar and cannula, through which a disinfectant or bactericide could be applied to the sac or location of the pus.

I am, Sir, yours truly,
JOHN ROCHE, M.D.
(Retired Ind. Med. Serv.)

Kingstown, July 26th, 1902.

DR. MINCHIN'S TREATMENT OF PHTHISIS WITH GARLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having sent a number of phthisical cases to Dr. Minchin at Kells Hospital for treatment, and seeing the wonderful effects which followed, I give a brief history of two cases:—

1. E. K., æt. 17. Hereditary tendency; had pleurisy two years ago; for past eighteen months cough; evening temperature, 101°; perspired very much during night. On examination, dulness over both apices; bronchial breathing; râles. By microscope, tubercle bacilli numerous. Patient was rapidly losing ground under hygienic treatment combined with the ordinary medicinal (creosote, ol. morr. and urea). After being eight weeks under Dr. Minchin, the effects were astonishing, cough and night sweats disappeared; evening temperature normal; sputum showed no tubercle and patient gained 14 lbs. in weight.

2. J. S., æt. 26. No hereditary tendencies; complained of pain in chest; cough and night sweats; evening temperature 100°; sputum showed tubercle bacilli. Same treatment followed as in Case 1 without satisfactory result. After being five weeks under the garlic treatment with Dr. Minchin, the pain in chest, cough and night sweats disappeared; temperature normal, and patient has resumed his occupation.

The cases above enumerated and many others, have convinced me that the results obtained by garlic treatment justify all Dr. Minchin claims for it.

I am, Sir, yours truly,
JOHN BRANGAN, L R.C.P., L.R.C.S., ED,
Medical Officer, Kilsteer.

Kells, July 19th, 1902.

INSANITY AND CRIME.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Agreeing with much of your recent article, may I remark that I do not think the question of moral *responsibility* is the most important in the case? A man may have enough mental capacity to know that he is doing wrong, and yet there may be no sufficient reason for treating him as a criminal. It is not every wrongful act that is a crime. We have ceased to treat adultery as a crime. Has it ceased to be wrongful? The true object of punishment is (or at least ought to be) not to give every man what he deserves, but to protect the public. Now, so far as the individual is concerned, the public is as well protected by locking him up in a prison or an asylum as by hanging him. If it is better to hang him the reason is that this punishment has a greater deterrent effect on other people who are meditating murder. But has the hanging of weak-minded or "cracked" people the deterrent effect upon others? Men and women of ordinary intellect would know that if they committed murder they would have no chance of "getting off" on this plea; while weak-minded, excitable, eccentric persons who are verging on insanity or idiocy are not likely to be deterred by any example of carrying out the extreme penalty on persons like themselves. The ends of punishment would therefore, I think, be equally met by locking these persons up in some asylum, at least until it could be asserted with considerable confidence that no danger to the public would be involved in a release. There should, I think, be special prisons, or, rather, asylums, for their reception, and a medical certificate of lunacy should not be required for admission.

I am, Sir, yours truly,
M.A.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

THE REBUILDING OF THE ROYAL INFIRMARY.

THERE has been so much published in medical and other journals during the last twelve years about the rebuilding of the Manchester Royal Infirmary that all persons not directly interested have become thoroughly tired of the subject. The matter is, however, one of great importance both to the sick poor of Manchester and district and also to the medical school, whose work is mainly conducted in the infirmary and the Owens College. The present building is an ancient structure situated in the centre of the town in an open space which belongs to the institution, and measures nearly five acres. There are not quite three hundred beds for patients, and the accommodation for nurses, servants, and officials, who number considerably over one hundred, is by no means satisfactory. There is, of course, a very large out-patient department, which is worked in premises far from roomy. All are agreed as to the need for a new and enlarged building, but difficulty is experienced in determining where to put it. The College is about a mile from the infirmary, and half a mile from the College a good site is offered to the institution *free of cost*. Ordinary people think that this site should be used for a new building, as it would be near the College, in purer air than that found in the centre of the town, near enough to the main road for convenience and far enough from it to ensure comparative quiet. For accidents, emergencies, and the out-patient department provision would be made on the old site. Either the present buildings could be retained for this purpose, or the land could be sold, a corner of it being reserved for the erection of a building for accidents and out-patients. A strong party, however, is in favour of rebuilding on the old site, and the board of management has again submitted to the trustees plans for this purpose. At the meeting of trustees, however, a large majority threw out the scheme, so that there is still a chance that the institution may ultimately be well worked in two buildings, one in town, the other a little distance out and near the College.

THE BRITISH MEDICAL ASSOCIATION IN MANCHESTER.

THE annual "picnic" of the British Medical Association is being held in Manchester during the present week. It is no less than a quarter of a century since the last annual meeting was held in Cottonopolis; the Association met in Manchester for the third time in 1877, and an attendance of over 700 was recorded, the scientific work being carried on in six sections. The present meeting promises to be a record one in point of numbers. There are seventeen sections, and great pains have been taken to secure success. Mr. Walter Whitehead, as President, will have ample opportunities for displaying his characteristic tact and *bonhommie* in guiding the Association through its "transition" from ancient government to modern management. The meetings are being held in the noble buildings of the Owens College, the general meetings assembling in Mr. Waterhouse's elegant creation, the Whitworth Hall. An attractive programme has been arranged.

As we write many of our foreign and Colonial visitors have already arrived, bringing with them apparatus specimens, and, it is said, even patients to show to us. Our thanks are due to them for the care and trouble they are expending in thus contributing to the success of the occasion. The meetings for business are not attracting much attention. The reform of the Association may be far advanced by the end of the week, but few of the members will be aware of it. Many object to the alterations in the constitution, but they know and care little about the Association as apart from the journal. They will probably forget even to send in their resignations, although quite a number have at one time or another expressed their intention of doing so should the B.M.A. come to resemble a trades' union too closely.

On Monday evening the annual Museum and Exhibition was officially opened by the Lord Mayor. A Cathedral service was held on Tuesday morning, the sermon being preached by Bishop Thornton. At the same time a Roman Catholic service was held. Mr. Whitehead gave his Presidential address on Tuesday evening, after which a *soiree* was held in the Owens College.

The work of the sections commences this morning (Wednesday). Excellent accommodation is provided by the well-equipped theatres of the Owens College, but the widely separated centres make "rapid transfer" no easy task. The seventeen sections find employment for 108 "officials." Special discussions have been arranged for in most of the sections. In Medicine, dilatation of the stomach and the differential diagnosis of functional and organic paralysis are to receive consideration. A special feature will be the demonstrations of clinical apparatus and methods of research.

In Surgery, the treatment of inoperable cancer and tuberculosis, disease of the testis, vesiculæ seminales, prostate and bladder will receive attention.

In the Obstetrical and Gynæcological section discussion will centre on the modern indications for Cæsarean section and the operative treatment of prolapsus uteri.

Public Medicine presents such attractive matters as vaccination, "return cases" of scarlet fever, the prevention of tuberculosis, the relation of poverty to disease, and the arsenical poisoning.

In the section of Psychological Medicine, syphilis as a cause of insanity will afford material for much discussion.

In the department for Physiology and Anatomy new views are expected regarding the development of the human genito-urinary organs.

The pathology of nerve degeneration will be discussed in the Pathological section.

The value of physical exercises in diseases of the respiratory tract offers subject for tempting discussion in the section dealing with Diseases of Children.

Much clash of arms will be heard in the field of ethics over such matters as contract practice, medical education and organisation, and hospital reform.

The important section devoted to Tropical Diseases, will deal with beri-beri, dysentery and yellow fever.

And in most of the sections numerous papers are down for a hearing.

It would add much to the interest and value of the work of the Association if a summary or abstract of every address and paper could be made available for every member, as is now the custom with many congresses.

Entertainments and Excursions.

The hospitality of the North is proverbial. Manchester is determined to present a very definite demonstration of the necessity for retaining this view. Among so much that is attractive choice is difficult. To-night (Wednesday) after Sir Thomas Barlow's address in medicine, an open-air reception and fête is to be held in Whitworth Park. It is to be hoped that "Manchester weather" will be conspicuous by its absence on this occasion.

On Thursday the annual dinner will be held, and a ladies' reception and variety entertainment takes place at the Prince's Theatre.

On Friday the Lord Mayor holds a reception and conversazione in the Town Hall, after which a ball is arranged for in Platt Hall Park.

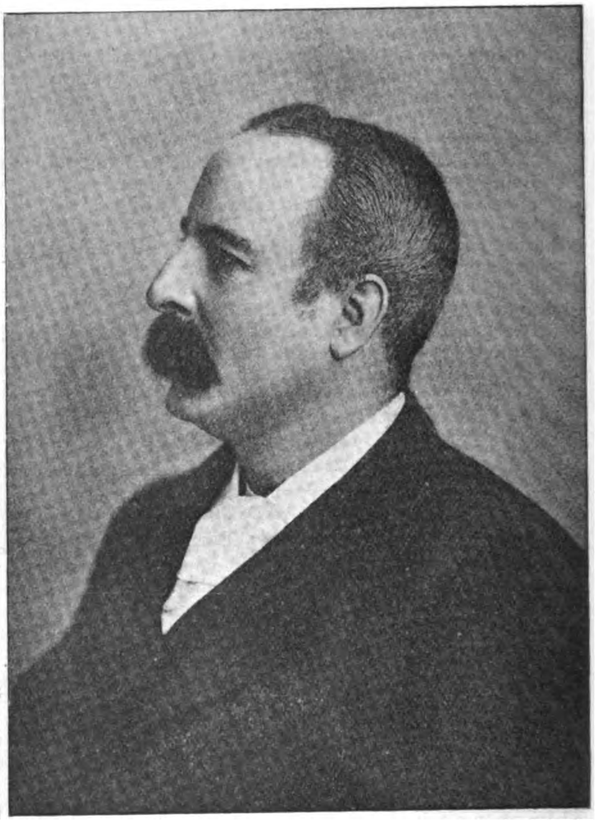
Every afternoon garden parties are being held. A very attractive series of excursions have been planned for Saturday. Various institutions in Manchester and Salford and the district will be open to visitors during the week.

An excellent "Handbook and Guide to Manchester" has been prepared under the direction of Mr. J. Howson Ray, giving very full descriptions of almost every feature of the district and phase of life likely to interest visitors.

The annual medical temperance breakfast is to be held at the High School for Girls on Thursday, July 31st, at 8 a.m. Sir Victor Horsley, F.R.S., will occupy the chair, and Sir Thomas Barlow, Bart., hopes to be present. Professor Sims Woodhead and others will take part.

The Dean of the Medical School of the Owens College, Professor A. H. Young, is prevented from attending the meeting by illness.

A number of American medical men are expected to be present and take part in the meetings, including Professor Osler and Professor T. M. Rotch.



The President of the British Medical Association.

The Manchester meeting of the British Medical Association is fortunate in being presided over by one who, in addition to local fame, has earned world-wide distinction. Mr. Walter Whitehead is essentially a Manchester man. He received his professional training in the old Royal School of Medicine in Manchester and qualified in 1864. He has occupied important posts in connection with many of the local hospitals, and is now Consulting Surgeon to the Royal Infirmary, the Manchester and Salford Hospital for Diseases of the Skin, the Lock Hospital, the Cancer Pavilion, and the Victoria Dental Hospital. Until recently Mr. Whitehead held the Chair of Clinical Surgery at the Owens College, and was examiner in the Victoria University. Mr. Whitehead has for long taken an active part in all matters concerning the welfare of the profession, and has acted as president of several important societies. The new President is also interested in Army and Navy work, and is honorary colonel of the Manchester Volunteer Medical Staff Corps. To medical literature he has made many notable contributions. In operative surgery Mr. Whitehead has been an able pioneer; it is hardly necessary to remind our readers of his work on excision of the tongue, and his very satisfactory method for effectually dealing with hæmorrhoids.

It is not for us to speak of Mr. Whitehead's ability as a public man, or charm in private life, but it may be said that Mr. Whitehead has a true Englishman's enthusiasm for sport, and is a keen yachtsman.

We heartily congratulate Mr. Walter Whitehead on the honour of being President of the British Medical Association, and trust his year of office will be marked by the blessings of peace and prosperity.

Literature.

CRAIG ON MALARIAL FEVERS. (a)

The author himself tells us that his purpose in the production of this work has been "to describe minutely certain fevers as yet too little understood by the mass of the medical profession, and which are of the greatest interest, both from a scientific and a practical point of view." The materials from which this very instructive volume has been prepared were very largely derived from personal observations and investigations made in the United States military hospitals. In their collection and arrangement he has been employed for nearly three years. How very much called-for this new departure in clinical and pathological observation really was, is impressed upon us by the first item of the information which he gives us regarding the previously existing state of knowledge in the most responsible quarters. He tells us that where his first work in this connection was carried out, at Chickamauga Park, "hundreds of cases of typhoid fever, pure and simple, were diagnosed as remittent malarial fever and treated as such, this being due very largely to the belief that because this camp was located in the south, it must necessarily become infected by malaria. As a matter of fact, there was but very little malarial fever present among the troops at Chickamauga Park, as has been amply shown by Vaughan, Dock, Reed, Shakespeare, and other investigators. The colossal mistake of diagnosing hundreds of cases of typhoid fever as malaria was really responsible for the terrible epidemic which actually compelled the evacuation of the Park as a camping site."

Dr. Craig divides malarial fevers into three classes: tertian, quartan, and estivo-autumnal; "each caused by its own distinct blood parasite, and each presenting distinct and more or less characteristic symptoms." He points out that as the tropics are approached, we meet less and less frequently with the benign tertian and quartan types of fever; their place being represented by the more severe and resistant estivo-autumnal infections, which "include also the terrible, pernicious malarial fever and the so-called black-water fever." The types of these fevers present so many and so variable features as to give rise to a good deal of complication—and even confusion—in the descriptions of the various authorities; "but all depend for etiology upon the presence in the blood of those forms of malarial plasmodia known as the estivo autumnal parasites or plasmodia of Laveran. We may say then that estivo-autumnal or remittent malarial fevers are fevers caused by the presence in the blood of definite blood-parasites, and characterised clinically by paroxysms of fever of regular or irregular duration, followed by regular or irregular intermissions or remissions."

The types of malarial fever are indeed among those which are the most clearly described by ancient and by mediæval medical writers. It was in 1712 that Torti distinguished them from other types of fever by their yielding to quinine, and it is since the date of his investigations that they became universally known as "malarial." Our author, we are very much pleased to observe, points out that the quinine test is not always a trustworthy one—especially in cases of estivo-autumnal fevers, "and should never be used for diagnostic purposes if a microscopic examination of the blood can be obtained."

The suggestion of a parasitic origin of the disease dates somewhat further back than the structural foundation of bacteriological pathology itself. Mitchell, in 1849, in his work on "The Cryptogamous Origin of Malarious and Epidemic Fevers," advanced the theory that the disease was really produced by the presence of spores which are indigenous in marshy districts; and the parasite, whose specific causal relationship to the phenomena of malaria has been fully established by Laveran, would appear to have been seen by Meckel in 1847, and by Virchow in 1848.

The volume now before us contains an excellently written account of the malarial parasites and their connection with the morbid phenomena to which their presence gives rise in the human body. A large proportion of the author's work is new; so that his opinions and views on some headings of his subject-matter will, of course, require further corroborative testimony before final acceptance. But his opinions, and his judgments of the opinions of his predecessors in this tangled forest of research, are always given clearly and without prejudice. As a specimen of his judicial adjustment of the scientific balance, we may offer the following; it relates to the various explanations which have been offered of the pyrexia of the malarial paroxysms since the discovery of the parasites:—"To Bacelli, however, we owe the most reasonable theory of the rise of temperature in malaria, and the one which is to-day accepted by most authorities. He suggested that during segmentation and the entrance of the young parasites into the blood, certain toxic products were liberated, which produced the fever. These toxic products he considered to be chemical products of unknown nature, formed during the development of the parasites within the red blood corpuscles and liberated during sporulation. This theory has been accepted by Marchiafava, Bignami, Mannaberg, Golgi, Thayer, and others. I believe that this theory explains most fully the rise of temperature in malarial fevers, and, reasoning from analogy, that it is without doubt correct. From our knowledge of other infectious diseases it is impossible to believe otherwise than that the fever of malaria is due to the liberation of toxic products in the blood during the segmentation of the parasites." He follows up the confirmatory considerations which further favour the acceptance of this theory to a distance to which we cannot, of course, follow him in the space afforded by our necessary limits. But we will say, in this connection, that we feel satisfied that his reasoning is as nearly perfect as it can be made in the present imperfect state of our data. We will only express the further hope that Dr. Craig will not discontinue his investigations in this hitherto obscurely mapped and measured domain of clinical pathology till he has thrown his searchlight into all its dark places.

We must notice, before concluding, that the author has not considered the subject of hæmoglobinuric fever. His own explanation of the omission is: "As the etiology of hæmoglobinuric fever is still somewhat in doubt, and as there are many excellent treatises upon it, I have thought it best to ignore it entirely." We commend Dr. Craig's discrimination. He took up the items of research which afforded him a definite starting point; and he has pursued his investigations with honour and enlightenment to himself, and with a full share of the latter to his professional brethren throughout the world. And we will close this notice by recommending to all medical men the perusal of his volume, and requesting the author to go on with the good work in which he has been so successful during his three years of probation.

(a) "The Estivo-Autumnal (Remittent) Malarial Fevers." By Charles F. Craig, M.D., Pathologist and Bacteriologist to the Army General Hospital. Illustrated by Two Coloured Plates and Twenty-one Clinical Charts. Imperial 8vo. Pp. viii. and 221. London: Bailliere, Tindall and Cox. 1901. Price 10s. 6d.

MERCIER ON INSANITY. (*a*)

As an introduction to the study of mental diseases the medical student will find in this admirable little book a very clear and lucid statement of the elements of insanity. Among other good points it presents new features in the classification of diseases of the mind, features which help in a very real way to overcome the difficulties of classification, so long a stumbling-block, especially to the student of medicine and to the busy general practitioner. Starting with the dictum "that there are not insanities but insanity only," Dr. Mercier logically regards the sub-division into forms of insanity and varieties of insanity, as meeting all the requirements of classification. By this broad distinction he simplifies the study of mental diseases, and in the pages of this volume presents to the student all the fundamentals of an elementary examination into diseases of the mind. This attempt to treat the various forms and varieties of insanity as types, brings the study of mental diseases more into line with the recognised study of bodily disease, a form of insanity corresponding with what is called in ordinary modern phraseology a symptom, a variety of insanity corresponding with what is called a disease, which may exhibit different symptoms at different times, or at the same time. One of the most interesting chapters is that in which the author deals with the causes of insanity; he is, however, too sarcastic when he regards toxins "as a very comforting word, which enables us to believe that we know far more about the causation of insanity than we did when we ignorantly called them poisons." The toxin theory, which is engaging so much attention at present as a causation of insanity, deserves in our opinion much more consideration. A complete index would have enhanced the usefulness of the book.

PUBLIC HEALTH AND HOUSING. (*b*)

LONDON and other large cities are so rapidly increasing as human centres that the problem of housing in relation to personal and public health has to be faced under new and but little known, and at present ill-defined, conditions. Dr. Sykes has, therefore, done well in presenting the profession with the substance of his valuable Milroy Lectures in so complete and convenient a form, which should be studied with profit by all interested in the matter of public health. To architects and all concerned in the erection and control of buildings for habitation the work will prove of the greatest service. In style and presentation it is so clear and lucid that even the ordinary layman may well find matter for thought and practical assistance in its pages.

Dr. Sykes devotes his attention mainly to conditions met with in the metropolis. Here the growth and pressure of population is necessarily altering the mode of living. The exclusiveness of the house of former days is giving way to a closer association of habitations. Mansions are now often shared by families; flats are springing up on all sides; boarding-houses and residential clubs are increasing in number; hotel life is becoming fashionable existing houses are being more and more sub-divided into tenements; flats of a small kind are becoming numerous; poor men's hotels or cubicle lodging houses are popular; and family lodging houses or boarding houses are coming to the front. The housing question, therefore, becomes the dominant factor in the maintenance of the health and vigour of the people. As the people become more and more town bred the necessity for ensuring conditions which will maintain the stamina, energy, and health of the population is seen to be of paramount importance. Dr. Sykes seeks first to ascertain the effects of such conditions of habitation as density of population, kind of dwellings, air supply and the like on the health of the people. He then passes to a discussion of the problems of construction and misconstruction. The various forms of street and house arrangement are described, and the classes of domestic buildings and dwellings, and their arrangement made clear by excellent diagrams.

In constructing dwellings for working-class families it is shown that if the rooms are too few there will be overcrowding, while if too many they will be sub-let. "The least danger lies in building for medium-sized families, the number of dwelling-rooms not being less than two and limited to four on the score of expense, remembering that there are practically three *sexes* to provide for, the married, the boys and the girls."

The chapter devoted to the consideration of domestic and sanitary conveniences is of much value, and well indicates their importance in regard to health. Perhaps the most attractive portion of the volume is that devoted to the usage and mis-usage of dwellings. Here are considered such matters as arise from pressure of population and overcrowding, tenement houses and tenement dwellings, and the registration of tenement houses.

A very useful section is devoted to a comparison of life on "floors" with that in "flats." Here Dr. Sykes very wisely shows that "with the increase in the size of dwelling-houses and the increase in the sub-division of houses into separate dwellings the urgency of legislation on the lines of the dwelling as the unit becomes greater and greater, and no approach to any satisfactory handling of the housing question, at least in the Metropolis, will ever be reached until this unit is adopted as a fresh starting basis."

Dr. Sykes is to be congratulated on having accomplished a difficult task with such success as merits not only the commendation of all his fellow medical officers of health but the approval of every medical man, and the thanks of each thoughtful member of the public.

HEALTH OFFICER'S POCKET-BOOK. (*a*)

A COMPARATIVELY long period of time—nearly ten years—has elapsed since the first edition of this book appeared, during which sanitary science has, we hope, made rapid progress. For this reason the task of bringing the text up to the standard of recent knowledge can have been no very light one, and we must confess the author has, on the whole, satisfactorily accomplished it.

The general arrangement of the book does not, however, strike us as being a peculiarly convenient one, too much tendency, consistent with ease of reference, being shown to deal with different parts of the same subject under separate sections. For instance, one part of sewage disposal appears under the heading of "Sanitary Memoranda," another under that of "Sanitary Practice." The same remark applies to water and water supplies, and while speaking of this subject we would draw attention to a recommendation the author makes, and which we cannot look on as otherwise than a grievous error. On page 109, under the head of "Constant and Intermittent Service," we read, "In very poor quarters public hydrants would be preferable," *i.e.*, to house taps on rising main. The modern tendency, and rightly so, is to give the poorer classes a supply of water in their own houses adequate for all purposes, and we can hardly believe that the author intentionally advocates a system which renders personal and household cleanliness a matter not only of great difficulty but almost an impossibility for them to attain. Ample supply of pure and efficient methods of removal of waste water, are surely two objects of the highest importance to all classes, and we may add, the poorer the class the greater the necessity for them. Again, on page 99, the author states that the necessary consequence of the construction of costly sewerage works in small towns is to foul the river and rob the land of its due, and we protest against any such tendency. Neither contention when examined will, we think, be found wholly accurate. It is now several years since Mr. Dibdin first observed the interesting fact that minnows were able to live and thrive at the outfall from his experimental contact beds at Barking. Other experts have

(*b*) "The Influence of the Dwelling upon Health in Relation to the Changing Style of Habitation. Milroy Lectures, 1901." By John F. J. Sykes, M.D., D Sc., Medical Officer of Health, St. Pancras. Pp. 216. London: P. S. King and Son. 1901.

(*a*) "The Health Officer's Pocket-Book." By Edward F. Willoughby, M.D., D.P.H. Second Edition, revised and enlarged. Pages xxii. and 400. Index xxiv. London: Crosby Lockwood and Son. 1902.

since noted this and further proofs of the high state of purity which can be attained in a sewage effluent. We have ourselves seen effluents kept for months without undergoing any secondary decomposition. River pollution is, therefore, not a necessary consequence of sewerage works, but points to some fault either in the initial scheme or in its subsequent working. For his other contention there is perhaps more to be said, although the ultimate effluent from some of the modern methods of sewage treatment, containing as it does a large amount of nitrogen in the form of nitrates, must have considerable value as a manurial agent when allowed to irrigate over land before final discharge into a river.

A large part of the work—nearly one half—is devoted to sanitary law, a collation of corresponding sections of the Public Health Act, 1875, and of London Act, 1891, being made which should prove useful. Perhaps those parts of the book which please us most are the first three sections of Part I. These contain a mass of useful information and formulæ of the very kind which is most difficult, to many persons at all events, to remember, and which is here set out concisely and accurately, justifying to a great extent the title of the work as a "Health Officer's Pocket Book."

INFECTION IN PUBLIC VEHICLES. (*a*)

The impression left on us by Dr. Greenwood's pamphlet is the urgent need for fresh legislation, without which we fail to see how the evils mentioned by him can be overcome. We should be more than glad to see an appeal made to the electorate by one of the great political parties, based on the "omnia sanitas" cry of Mr. Disraeli in the seventies, from which such important reforms resulted. From his official position as medical officer of health for Crewe, Dr. Greenwood has an almost unique opportunity of forwarding his crusade against the almost universally existing insanitary condition of railway carriages, and we feel no doubt whatever but that his opinion will favourably influence the management of the most powerful railway organisation in this kingdom. The crusade against tuberculosis is as yet in its infancy, and Dr. Greenwood has done good work by placing on record, in language so concise and simple as to be easily understood by the man in the street, the result both of his own experience and that of other workers in the same field. The difficulties of the problem are not by any means insuperable and the aim in view should be capable of being accomplished without trenching on that supposed personal liberty upon which we are perhaps apt to lay a little too much stress. It is no infringement of liberty to prevent a tuberculous person from becoming a source of danger to the community by spitting in railway carriages than it is to detain a small-pox patient in an isolation hospital. As Dr. Greenwood says, legislation and education are the most important factors in carrying on this war against tuberculosis, in both of which essentials we are at present far behind some other countries.

The pamphlet before us might with advantage be read and acted on by all.

SMOKE PREVENTION. (*b*)

The opinion of an expert on a matter of public importance is always of value, and certainly no fault can be found with Mr. Nicholson's work on the score of lack of experience and knowledge of the subject with which he deals. From a perusal of the book it is evident that it is the result both of a thorough acquaintance with the evils of the smoke nuisance and of a careful study of the best means available at present to prevent such. The author perhaps makes rather too sweeping a statement on page 36 with regard to the amount of CO_2 found in air, when he asserts "that all the carbonic acid made by the furnaces of the greatest manufacturing centres has failed to make any addition which chemical analysis can detect to the natural proportion" (viz., ·4 per 1,000 volumes, not 4 as he gives the figures) "in which that gas exists as an element of the atmosphere." This figure does not correspond with the amount found by Angus Smith and other observers in some of the large cities, as for example in the case of Glasgow, where the average is ·5 per 1,000. Again, on the next page we find the statement that about 150 cubic feet of air are required for the combustion of 1 lb. of coal. For practical purposes, we think this is put at much too low a figure and that more usually, at least once and a half this quantity, will be found necessary. These comparatively minor faults do not however, detract much from the general merit of the book, which might with advantage be placed in the hands of all persons having control of furnaces to whom we can commend it. The true solution of the smoke nuisance is perhaps yet to be discovered, and may we think, be found in the general employment of electric power generated from a central station situated in some position, remote from habitations and possibly with advantage controlled by the municipality.

Apart from a somewhat curious chronological error and one or two minor faults, the text is carefully and clearly written and the illustrations excellent, while the general production of the book leaves little to be desired.

DAVIES' HANDBOOK OF HYGIENE. (*a*)

We are pleased to see a second edition of this book, which is one of the best of its kind we are acquainted with, and which needs no apology for its existence. Lieutenant-Colonel Davies has succeeded in presenting in a most readable form the more valuable parts of the standard works of such authorities as Du Chaumont, Parkes, Wynter Blyth and other distinguished investigators in the field of sanitary science, while his own experiences, both in India and at Netley, only enhance the general merits of the work. The subject matter is clearly written and has been brought well up to date; and, although in the main all chapters in the book are worthy of perusal, those on "Food" and "Water" seem to us to be the most meritorious. It is, perhaps, to be regretted that the subject of Vital Statistics, considering its importance, has had such a limited space devoted to it, a fault which might with advantage be corrected in a future edition, even at the expense of a trifling increase in the size of the book. As we have said, we know no better work of its kind, and we can with confidence commend it to all as a handy book of reference, but more especially to those who have not convenient access to more pretentious volumes.

INDEX CATALOGUE. (*b*)

It is difficult to convey to the reader who has not seen and consulted one or more of the preceding volumes of the "Index Catalogue" the boon that the United States Government has conferred on the medical profession by the publication of this great Index, of which the present volume is the sixth of the second series. It includes in its 1,051 quarto pages 15,589 author-titles, representing 5,865 volumes and 14,296 pamphlets. It also contains 5,962 subject-titles of separate books and pamphlets, and 30,561 titles of articles in periodicals. The word "gonorrhœa" occupies 80 closely-printed columns, and "gout" 30 columns. On page 408 we find the notorious mountebank, James Graham, occupies nearly a column with his "Discoveries, Improvements, Methods of Treating Diseases, Temple of Health, and General Electric Apparatus." "Great Britain" occupies 92 columns, and the comparatively new specialty, "Gynæcology," 42 columns. The greatest number of references, however, occur under the word "Heart," which fill 246 columns. All that careful editing, sub-titles, the use of different types and beautifully

clear and distinct type can do to facilitate reference has been done. The Surgeon-General's Library at Washington now contains 138,078 bound volumes, and 235,127 pamphlets.

The number of titles in the Index-Catalogue, so far as published, are:—Author-titles: Titles, 241,596; volumes, 115,739; pamphlets, 212,099. Subject-titles: Book-titles, 215,286; journal articles, 696,457.

All who have occasion to consult the Index must feel grateful for the generosity and thoughtfulness of the Great Republic that bestowed on the profession this great work, which facilitates the work of every medical scholar, is rich in suggestion to every thoughtful reader, and invaluable to all medical writers.

Laboratory Notes.

BRAND'S FEVER FOOD.

Prepared by Brand and Co., Mayfair.

This preparation has now become almost too well-known to require further commendation.

It is conveniently put up in small tins opened with a key, and its merits should ensure its being invariably included in the equipment of every traveller to tropical climates. A combination of essence of beef, egg and cream, its efficacy in sustaining the vital powers in fevers, and its property of easy assimilation make it the most valuable of foods in all malarial climates. In cases where the stomach rejects even milk and soda water, this food can be administered with success. If ice be obtainable the tin may be placed on it; if not the tin may be wrapped in a wet flannel and suspended in a draught. The jelly thus cooled is administered in a teaspoon without any admixture, and only those who have experienced its advantages can duly appreciate its value. We have analysed it on a previous occasion, and now find its composition to be practically the same. We would earnestly commend all medical officers and others proceeding to malarial districts to take a good supply of this preparation, which will afford them the means of greatly alleviating the suffering consequent on malaria in its severest forms and in all probability the satisfaction of knowing, as does the writer, that by its aid they have saved lives that might otherwise have been lost.

BRAND'S MEAT JUICE.

This meat juice, which is extracted from the best beef in the cold, must be clearly distinguished from the ordinary meat extract, to which it is greatly superior in composition and digestibility. We find on analysis that it contains nearly half its weight of assimilable nutrient materials, of which a large proportion is coagulable albumen that is not overcrowded with mineral matters, which are a great drawback in many meat preparations, containing as they do large quantities of salt.

The essence has a very agreeable flavour of fresh meat, and will keep good any length of time when unopened. It may be given either alone, when it is perfectly palatable, or mixed with aerated water. In the case of wasting diseases, fevers and the like, it does not produce nausea and is retained by the stomach (we are speaking from actual experience) when many other foods are instantly rejected.

FRIEDRICHSHALL MINERAL WATER.

We have analysed this well-known natural aperient water, and find its mineral contents coincide remarkably closely with the analysis made by the authorities at the Breslau Municipal Laboratory, who make a periodical examination of it.

This water contains a very valuable combination of sodium and magnesium salts in proportions which, while free from the nauseating taste possessed by some aperient waters, is effective and not disagreeable to take. It is exactly what is required by travellers proceeding to hot climates where a mild but effective aperient is a frequent necessity. It is most effective when taken on rising in the morning, and is free from the objection which is commonly experienced after the frequent use of drastic drugs like calomel, which have to be taken in increasing quantities to procure the desired effect. Of this water, on the contrary, the quantity needed is decreased by prolonged use.

Medical News.

Liverpool School of Tropical Medicine.

Major Ronald Ross, C.B., F.R.S., F.R.C.S., has been reappointed to the position of Walter Myers lecturer to the school.

Royal University of Ireland.

At the meeting of the Senate on July 24th the following were appointed as Extern Examiners for the autumn examinations, 1902:—In Surgery: Charles Stonham, F.R.C.S.E. Midwifery: Henry Jellett, M.D. Pathology: Alexander C. O'Sullivan, M.D. Opthalmology: William G. Syne, M.D. On the motion of Dr. Cox, seconded by Dr. M'Keown, Sir Christopher Nixon was unanimously reappointed as representative of the University on the General Medical Council for the ensuing five years.

The Census of Dublin.

The census returns for 1901 relating to the city or county borough of Dublin, which have just been published, are very interesting reading for all who take an interest in sanitation. In 1891 the population was 268,650, and in 1901 it had increased to 290 638, an increase of 8·21 per cent. The number of tenements of one room in the city was 21,747, comprising 3,278 cases in which the room had only one occupant; 13,320 where the room had 2, 3, or 4 occupants; 4,576 cases in which there were 5, 6, or 7 occupants; and 573 cases where the occupants exceeded 7 in number, including 47 cases of 10 persons, 13 of 11 persons, and 6 of 12 or more persons in the room. Of the whole population in 1891 24 per cent. could neither read nor write, and in 1901 the percentage of illiterates had fallen to 19·7. From these official returns we see in great part the reason of the abnormally high death-rate that is characteristic of Dublin. We find 36·6 per cent. of all the families of the city occupying one room; some 100,000 people in insanitary rooms, for the room-keepers' dwellings are insanitary to a disgraceful degree; but this condition need not be allowed to exist. There is no reason why the one room of the labourer should not be clean and healthy; and the making of it healthy and the keeping of it clean and healthy should be imposed as a duty on the owners of the tenement houses—houses that pay a very large percentage of profit to their owners. We would suggest that no house be allowed to be let in tenements until it is licensed by the sanitary authority of the city, and that, if from any cause the house is not kept in a sanitary condition, that the licence be revoked and the house shut. On each storey water-closets and lavatories should be erected, with, of course, an abundant water supply, and each lobby should be lit with gas or electricity. At present these dwellings are inhabited by the poorest and most decrepit of a large city, they become a very nidus of disease, and the owner of a few tenement houses accumulates a fortune in a short time at the expense of the health of the community. Being let to room-keepers, each house is valued at a small sum; the rates are consequently low, but the death-rate is abnormally high; the young, especially the infants, die like midges, choked with the polluted air they are compelled to breathe. It is a condition of life which should not be tolerated, one which the citizens should remedy. Men and women huddled together in these filthy tenement houses cannot enjoy good health; and it is difficult to see how they could live up to even a moderate standard of morality, seeing that their fellow-men are so indifferent to their sufferings.

Vital Statistics.

The deaths registered last week in seventy-six great towns of England and Wales corresponded to an annual rate of 14·5 per 1,000 of their aggregate population, which is estimated at 14,862,456 persons in the middle of this year. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—from measles: 1·6 in Portsmouth and in West Bromwich, 1·8 in Gateshead, 2·0 in Stockton-on-Tees, 2·1 in Reading, 2·7 in Bury, 3·6 in Rhondda, and 4·3 in Rochdale; from scarlet fever: 1·8 in Gateshead; from diphtheria, 1·3 in Rhondda; from whooping-cough: 1·1 in Hull, 1·4 in Norwich and in Sunderland, 1·5 in Leyton, 1·7 in Hanley, 1·8 in Smethwick and in Barrow-in-Furness, 1·9 in Southampton, 2·2 in Portsmouth, and 2·4 in Grimsby; from "fever": 2·3 in Ipswich, and 3·0 in Merthyr Tydfil; and from diarrhœa: 1·6 in Wolverhampton, 1·7 in Hanley, in Bootle, and in Middlesbrough, 1·9 in Rotherham, and 2·4 in Plymouth. The 27 deaths from small-pox included 15 belonging to London, 8 to Swansea, 3 to Gateshead, and 1 to Bootle. In London 2,657 births and 1,236 deaths were registered. Allowing for increase of population, the births were 78 above, and the deaths 438 below the average numbers in the corresponding weeks of the last ten years.

A Bye-law against Spitting.

The Home Office has approved a bye-law passed by the Glamorgan County Council prohibiting spitting in public carriages, waiting-rooms, public halls, and places of public entertainment. It is held that the bye-law cannot properly be made to apply to churches, chapels, schools, and shops, nor does this matter very much since it is the exception for even inveterate expectorators to "indulge" their filthy proclivity in places of worship, while in schools the delinquents can be whipped out of the habit, and in shops they can be summarily expelled.

Mortality of Foreign Cities.

The death-rates in the principal foreign cities of the world from which official returns are received by the Registrar-General, were for the last week per 1,000 living: In Calcutta 30, Bombay 37, Madras 29, Paris 17, Brussels 14, Antwerp 12, Amsterdam 15, Copenhagen 15, Stockholm 16, Christiania 15, St. Petersburg 24, Moscow 35, Hamburg 14, Munich 22, Vienna 17, Prague 21, Buda-Pesth 17, Trieste 25, Rome —, Venice 16, Cairo 49, Alexandria 33, New York 19, Philadelphia 17, Boston 14.

London School of Dental Surgery.

The following is a list of the principal prize winners, Session 1901-1902: The Walker Scholarship, Mr. F. Butler. The Saunders Scholarship, Mr. E. C. Sprawson. Ashs' Prize, Mr. H. Perkins.

Class Prizes.—Dental Mechanics: 1st Prize, Mr. F. E. Sprawson; 2nd Prize, Mr. F. Butler.

Dental Metallurgy: 1st Prize, Mr. C. Peacock; 2nd Prize, Mr. F. Butler.

Practical Dental Surgery: 1st Prize, Mr. F. E. P. Huddart.

Dental Anatomy: 1st Prize, Mr. E. C. Sprawson; 2nd Prize, Mr. F. M. Müller.

Summer Session, 1902.—Dental Surgery: 1st Prize, Mr. E. C. Sprawson; 2nd Prize, Mr. H. Perkins.

Dental Histology: 1st Prize, Mr. H. Perkins; 2nd Prize, Mr. A. A. Smith.

Prize for best Note Book and set of Microscopic Slides (given by the Lecturer): Mr. E. C. Sprawson.

Pass Lists.

The Royal University of Ireland.

The following passed the first examination in medicine in the Faculty of Medicine:—Madeleine S. Baker, James Barrett, Daniel Boylan, Harry L. Bristow, Francis X. J. Callaghan, George F. Campbell, Holden Carson, John Dunlop, John L. Dunlop, Patrick J. Dwyer, John R. Elwood, Eleanor E. Finegan, Edward FitzGerald, William J. Gallagher, James J. A. Gannon, James Gaston, Patrick J. Grogan, Rowland Hill, James J. Hollywood, James Horgan, Robert F. Kennedy, Charles G. Knight, Samuel W. Kyle, Thomas J. McAllen, Samuel McCormac, Jerome B. Murphy, Patrick F. Murphy, Joseph Nunan, Joseph A. O'Halloran, Humphrey J. O'Sullivan, Charles B. Pearson, Percy B. Ridge, Charles H. G. Ross, James A. Shorten, Thomas Tobin, Ernest F. Watson, Henry N. Wrixon.

Honours in Botany (Second Class).—Charles G. Knight.

Honours in Zoology (Second Class).—Francis X. J. Callaghan, Madeleine S. Baker.

Honours in Experimental Physics (Second Class).—Rowland Hill, Francis X. J. Callaghan, Charles G. Knight.

Exhibitions (Second Class, £10 each).—Charles G. Knight, Francis X. J. Callaghan.

University of Aberdeen.

At the graduation ceremony on July 23rd, the following degrees were conferred:—

Degree of Doctor of Medicine (M.D.).—Norman Wm. Anderson, M.B., C.M., Strathmiglo, Fife; James Fletcher, M.B., C.M., Ham Green Hospital, Bristol; Albert Henderson, M.A., M.B., C.M., Aberdeen; Albert Hogg, M.A., M.B., C.M., Old Trafford, Manchester; Douglas Whimster Keiller Moody, M.B., C.M., Montrose; Alexander Robb, M.A., M.B., C.M., Paisley; Percy Austin Roden, M.B., C.M., Droitwich; Robert Maxwell Trotter, M.B., C.M., Newcastle-on-Tyne; George Alex. Troup, M.B., C.M., Stratford, London. The theses of Messrs. Fletcher, Robb, and Troup were awarded "commendation."

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch. B.), New Ordinances, with Second-class Honours.—Charles Todd Andrew, B.Sc., Hamilton; John C. G. Ledingham, M.A., B.Sc., Boyndie, Banff; John Hector Stephen, B.Sc., of Aberdeen.

William Leslie Beaton, Perth; James Davidson, Cruden-by-Ellon; William Fraser, B.Sc., Forres; William Sim Garden, Brankanentham, Portsoy; George Eric Hamilton, Aberdeen; Thomas Barrett Heggs, West Bromwich; Donald J. G. Johnston, Culduthel Mains, Inverness; William Louis A. Leslie, Stonehaven; Alexander James Macdiarmid, Aberdeen; George Shiach McDay, M.A., Dufftown; Malcolm Macleod, Aberdeen; Thomas Basil Mitchell, Hillside, Montrose; Alexander Lumsden Ritchie, Schoolhill, Turriff; George Officer Robertson, M.A., Wateridgemuir, Ellon; John Rose, M.A., Leanach, Inverness; Francis William Squair, New Deer; Henry Watson, Norwich; Andrew Stewart Wilson, Aberdeen.

John Murray Medal and Scholarship (awarded to the most distinguished graduate, M.B., of 1902).—Lewis Davie Cruickshank, M.B., Ch.B., Tarves, Aberdeenshire.

The Alexander Anderson Scholarship.—John Charles Grant Ledingham, M.A., B.Sc., Boyndie, Banff.

Diploma in Public Health.—Henry Fraser, M.D. Aberd., Aberdeen, with credit; Wilfred Ernest Lawson, M.B., Ch.B.Aberd., Aberdeen.

Conjoint Examinations in Ireland.

The following candidates have passed the Second and Third Professional Examinations of the Royal College of Physicians and Royal College of Surgeons:—

Second Professional (Old Rules).—F. W. Brunker, Jas. Harvey, R. McElvoy, T. J. Ryan.

Second Professional, Part II.—1. Honours: M. Kearn, Miss G. W. Clark. 2. All Subjects: M. Antony, E. A. Bernard, M. Campbell, W. J. Cowell, T. J. Golding, K. P. Mary, R. H. Smythe, A. J. Swanton, W. Tobin. 3. Completed Exam.: L. A. Hynes, Miss F. J. Lardner, J. M. Moriarty, S. H. Robinson.

Third Professional.—Honours—Order of Merit: C. W. Ewing, J. P. Lynch (R. W. Burkitt, K. F. Fleury, equal). Passed all Subjects: R. J. B. Buchanan, J. Casey, J. Clarke, D. C. V. Fitzgerald, P. J. Irwin, J. P. Ryan, L. P. Stokes, G. C. Tabuteau. Completed Exam.: R. I. Gordon, T. Keogh, J. Nicholl, J. O'Doherty, W. J. O'Doherty.

First Professional.—*Errata*—Mr. A. J. Faulkner's name should have appeared third in the list of Honours. Mr. S. C. Clark should have been Isaac Clarke.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

WEDDING CUSTOMS.

The time-honoured custom of throwing rice at weddings has oftentimes proved disastrous to the eyesight of either bride or bridegroom. Simple confetti, although not without manifest disadvantages, is certainly less dangerous than rice. We therefore think the Dean and Chapter of St. Saviour's Collegiate Church. Southwark, are at least short-sighted in issuing a notice which says, "Confetti is a foreign importation and a special abomination. . . . Never use it: it is cheap and nasty. Use the good old-fashioned rice instead." Were the anathemas of Mother Church ever dictated by hygienic considerations?

Clipstone (Dorset).—You had better have the child examined for adenoids, the effects of which are far-reaching and general. The operation can be quite safely performed under chloroform. Have the teeth attended to by a competent dentist if you wish to treat the child scientifically.

Oxoniensis.—The Building Act of 1894 provides for structural exits from roof in case of fire under certain conditions: (1) if used as a dwelling-house or a factory over 30 feet in height; (2) if the topmost floor be over 60 feet from the pavement. The Act as it stands is urgently in need of amendment, both in the interests of the public and of workpeople.

BAKEHOUSE LEGISLATION.

To the Editor of The Medical Press and Circular

Sir,—Your comments on my letter of the 16th come to the point at once. You say, "of course, under careful precautions to prevent contamination by outside microbes." That is the question at issue, but it is not at all clear that Drs. Waldo and Walsh did take proper precautions. The exposure of the bread only a few seconds to the non-sterilised air of the room they were working in was quite enough to allow of contamination, and the results of the experiments, carefully set forth on pages 37 and 40, seem to me rather to favour this view. Dr. Waldo refers to "futher experiments with artificially-infected dough." One would be glad to see the result of these experiments, as the essential thing is to establish a causal connection between the germs in the dough and the germs in the bread. But this has not been done at present.

I am, Sir, yours truly,
Editor "The Baker and Confectioner."

July 23rd, 1902.

[In carrying out scientific bacteriological investigations it is always assumed that careful precautions are taken to exclude contamination by outside organisms whether from the air or other sources. Such exclusion is necessary to the experiments, and is always taken for granted when gentlemen of scientific standing publish the results of bacteriological investigation. Were every step and every precaution detailed in the formal description of work of that kind the size of our medical journals and books, as well as of our special libraries, would have to be quadrupled.—Ed.].

Medicus (Bucks).—The season of summer diarrhœa is now at hand, although it may be late this season owing to the low temperature. The malady is commonly associated with the abundance of plums and other fruit. It seems more than likely, however, in the light of recent scientific researches that the disease is due to the growth of bacteria, fostered by certain conditions of environment connected with a high mean temperature of earth and air.

Appointments.

Baumann, E. P., M.D.Edin., M.R.C.S.Eng., Medical Registrar to the Hospital for Sick Children, Great Ormond Street, London.

Bayly, H. **Wansey**, M.R.C.S., L.R.C.P.Lond., House Physician to the West London Hospital.

Dyer, C. **Harold**, M.D., C.M.Aberd., Medical Officer of Health to the Cleckheaton Urban District Council.

Evans, **Arthur**, M.S., M.D.Lond., F.R.C.S.Eng., Surgeon to Out-patients with duties at the Branch Hospital in the Royal Albert Dock of the London School of Tropical Medicine.

Greene, **Arthur**, M.D., &c., Dublin, House Surgeon, Royal South London Ophthalmic Hospital, Southwark, S.E.

Hunter, **William**, M.D.Edin., F.R.C.P.Lond., Physician to the London Fever Hospital.

MacDowall, W. M., L.R.C.S., L.R.C.P.Lond., Locum Assistant Medical Officer to the Glamorgan County Asylum.

Paton, Leslie, B.A., M.B.Cantab., F.R.C.S., Assistant Ophthalmic Surgeon to St. Mary's Hospital, Paddington.

Rigby, **Hugh Mallinson**, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the London Hospital.

Wallace, J., M.D.Aberd., Certifying Surgeon under the Factory Act for the Stonehaven District of Kincardineshire.

Woodhouse, C., M.D.Cantab., Certifying Surgeon under the Factory Act for the Urban Districts of Esher and the Dittons, East and West Molesey, and Walton-on-Thames.

Vacancies.

Ancoats Hospital, Manchester.—Resident House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Applications immediately to the Secretary.

Gravesend Hospital.—House Surgeon. Salary £90 per annum, with board and residence. Applications to F. H. Stevens, Hon. Sec., 146, Milton Road, Gravesend.

Haydock Lodge Asylum, Lancashire.—Assistant Medical Officer. Salary £175 a year, with furnished quarters, board, washing, &c. Applications to Dr. Street, Haydock Lodge, Newton-le-Willows, Lancs.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance. Applications to Dr. W. D. Moore, Medical Superintendent.

Hospital for Sick Children, Newcastle-on-Tyne.—Male Resident Medical Officer. Salary £100, with board, lodging, and laundry. Applications to Edward MacNay, Secretary.

Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum, with board and apartments. Applications to Sam. B. Leicester, Secretary, 56, Vauxhall Road, Liverpool.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £90, with residence, board, and washing. Applications to the Chairman of the Board of Management.

Newport and Monmouthshire Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary.

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Also one Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel are found for the above surgeons. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum. Applications to the Secretary, E. S. Baylis, 19, Moorgate Street, Rotherham.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance and washing. Applications to the Secretary.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. Applications to the House Surgeon.

St. Giles, Camberwell.—Assistant Medical Officer. Salary £120 per annum, with furnished apartments outside the Workhouse, and an allowance of £1 1s. weekly in lieu of board and washing. Applications to Charles S. Stevens, Clerk to the Guardians, Guardians Offices, 29, Peckham Road, S.E.

Sussex County Hospital, Brighton.—Second House Surgeon and Anæsthetist. Salary £80 per annum, with board and residence. Applications to the Secretary at the Hospital.

Torosay.—Medical Officer. Salary £100 per annum. Applications to John Livingston, Inspector of Poor, Auchnacraig, Isle of Mull.

University College Hospital.—Matron. Salary £125, with board, lodging, and washing. Applications to the Secretary, University College Hospital, Gower Street, London, W.C.

Births.

Adams Clark.—On July 18th, at 44, Beckenham Road, Penge, S.E., Josephine (Willoughby), the wife of Wm. Adams Clark, M.D., of a daughter.

Blomfield.—On July 24th, at Queen's Road, Peckham, the wife of Alfred Blomfield, M.R.C.S., L.R.C.P., of a daughter.

Finch.—On July 20th, at Purston, Yorks, the wife of W. Stanley Finch, L.R.C.P., M.R.C.S.Eng., of a daughter.

Hackney.—On July 23rd, at Hythe, Kent, the wife of Clifford Hackney, M.R.C.S., of a son.

Nightingale.—On July 23rd, at 26, Upper Phillimore Gardens, Kensington, W., the wife of Percy Athelstan Nightingale, M.D., of a son.

Rubra.—On July 23rd, at 39, Cecile Park, Crouch End, N., the wife of Henry H. Rubra, M.D., M.R.C.S., L.R.C.P., of a son.

Marriages.

Bowie—Martin.—On July 22nd, at St. John's Church, Weymouth, John Macaulay Bowie, M.D., M.R.C.P.Ed., second son of Robert Bowie, Edinburgh, to Jane Maude Julia Martin, eldest daughter of Mrs. J. D. Martin, Weymouth.

Lay—Ross.—On July 24th, at St. Mary Abbot's, Kensington, Charles Edward, only son of the late Joseph John Lay, M.D., Peasenhall, Suffolk, to Violet Barbara, third daughter of the late Hugh Ross, Esq., C.E., and of Mrs. Ross, of 3, Palace Gardens Terrace, Kensington, W.

Ward—Hill.—On July 22nd, at St. John's Church, Torquay, Thomas Hamilton Ward, M.D., of Paignton, to Emma Vivian, only daughter of H. Grylls Hill, Esq., of Hillesdon, Torquay.

Deaths.

Arnott.—On July 26th, at the Firs, Bath, Mary Ann, widow of Archibald Arnott, M.D., aged 91.

Bateman.—On July 21st, at Charles Street, St. James's, London, Frederick Augustus N. Bateman, M.D.Durh., aged 51 years.

Jones.—On July 27th, at 20, Addison Gardens, Kensington, Caroline, widow of Edward Jones, M.D., of Sydenham, aged 83.

Stedman.—On July 16th, at Redcliffe Square, S.W., John Buck Stedman, F.R.C.S., late of Godalming, aged 82 years.

Original Communications.

THE STUDY OF THE NATURAL HISTORY OF DISEASE THE BASIS OF ALL ADVANCE IN ITS TREATMENT.(a)

By SIR THOMAS BARLOW, BART., K.C.V.O., M.D., F.R.C.P.

Physician to His Majesty's Household; Physician to University College Hospital.

TWENTY-FIVE years ago the British Medical Association met in this city, and the Address in Medicine was given by one who fitly represented the Manchester School, and whose name is illustrious among the leaders of our profession in the Victorian epoch. William Roberts had many remarkable gifts, but the combination in his mental equipment of infinite painstaking in homely detail and of philosophical insight and foresight gave alike to his public utterances and to his conversation a suggestiveness and charm which can never be forgotten.

In drawing attention to some recent notable advances in the healing art, I will ask your consideration and support for this thesis: The advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease. I do not say that good treatment owes its origin entirely to pathology—far from that; it has often antedated pathology—but in proportion as pathology has become complete it has rationalised good treatment and refined it, separating, so to speak, the ephemeral from the permanent, the accidental from the essential, as well as the harmful from the beneficent. Moreover in these last days in not a few instances the true pathology has laid down new therapeutic lines which have been justified by experience.

BACTERIOLOGY AND TREATMENT OF DIPHTHERIA.

Let me choose as my first illustration one of that group of acute specific diseases to which in his discourse Sir William Roberts gave his chief attention. I will ask you, as practical men, whether there is any disease within your knowledge in which bacteriological investigation has made so profound a change in our attitude as to the malady and its treatment as it has in diphtheria?

Recall, I pray you, the chaotic and bewildering state of doctrine on this disease only a dozen years ago. There were the endless, and not altogether academic, disputes as to the difference between croup and diphtheria; as to whether there was a true membranous croup which was different from laryngeal diphtheria; and as to the diagnostic differential signs of diphtheria which appeared to elude the most careful anatomical definition. Malignant diphtheria of the throat was easy to diagnose, but as to the nomenclature of mild cases simulating follicular tonsillitis and of the throat exudations complicating scarlet fever, an experienced man was the last person to dogmatise. It was only, at length, by studying cases in epidemic groups, and especially by noting the paralytic sequelæ, that we learned how widely we had to cast our net in order to include examples in which there had been no visible membrane at all though there might in some of them have been exudation in the post-nasal region, and, for a time, thin irritating discharge from the nostrils.

And how exceedingly diverse were our opinions as to its ætiology. We were never prepared to deny that exposure to cold was a cause, and after cold came drains. Drain poisoning, serious as it is in lowering vital resistance and preparing a suitable soil, has been often made to bear more than its fair share in the immediate causation of specific disease, and diphtheria was a notable case in point. Sir William Jenner, whose enlightened doubts were nearly as valuable as his absolute statements, would never admit that the direct relationship of diphtheria and drain emanations was proved. But the confident assurance of many people on this doubtful point was often exceedingly mischievous, for though it led to sanitary investigations and helped sometimes to bring about sanitary improvements, it also led to the quiet ignoring of other possible sources of the disease. There was a time, not many years ago, when cases of membranous croup were treated in children's hospitals in ordinary wards, and there were those who stoutly maintained that these cases were not contagious.

The further study of epidemics led to the conclusive proof that in some cases the disease was disseminated by milk. Then came the observation that epidemics were often followed by sporadic cases, or preceded for a time by mild and ambiguous sore throats. Country villages and isolated homes gave their quota as well as crowded streets.

By degrees, even in apparently sporadic cases, we came to attribute more and more importance to insidious personal contagion, and to see that the disease was maintained and transmitted by the moving to and fro of slight cases, especially in schools and places where children were closely aggregated. Increase of the disease seemed to correspond with the period when compulsory school attendance was enforced, and there grew up a strong presumption in favour of the tenacity of infective material associated with bedding and clothing.

When the bacillus of diphtheria had been isolated by Klebs and the inoculation of it in animals had been demonstrated by Loeffler to produce diphtheritic lesions, the first step had been taken in unravelling the skein. First, the polymorphism of the bacillus is very suggestive. The long and short varieties it has been shown may occur as pure cultures or side by side, or in successive cultures apparently one form may be replaced by the other. Though these varieties cannot as yet be correlated to different types of membrane, yet their discovery prepares us for considerable variation in gross naked-eye characters.

Secondly, the variation in virulence of the bacilli going down to an actual vanishing point with little morphological alteration has its transcript in clinical experience. When, in an ordinary case of faucial diphtheria the nose becomes affected and a thin ichorous discharge appears at the nostrils the gravity of the case is always increased. On the other hand there are cases of children attacked with thick fibrinous exudation obstructing the nostrils in which the Klebs-Loeffler bacillus has been identified and yet there is little constitutional disturbance and apparently very slight infectivity. There is a form of chronic diphtheritic ophthalmia with thick exudation which presents many similar features.

(a) Abstract of Address in Medicine at the Annual Meeting of the British Medical Association at Manchester, July-August, 1902.

Thirdly, the detection of the diphtheria bacillus in the secretions of the throat in cases at first clinically indistinguishable from follicular tonsillitis, gives the clue to the puzzling cases which the study of epidemic groups had brought home to us—namely, that paralytic sequelæ can occur when most careful observation has failed to identify any antecedent visible membrane. The persistence, sometimes for months, of the bacillus in the fauces of those who have passed through an attack of diphtheria when all membrane has long since disappeared, gives us the clue to the occasional prolonged infectiousness of those who have had this disease, and seems to enforce the need of special arrangements for diphtheria convalescents. It is the experience of those interested in day-school epidemics that a slight nasal discharge associated with imperfect resolution of the lymphatic glands are the clinical danger signals to be looked for, and which suggest the bacteriological investigation for continued sources of dissemination.

But we are further indebted to the bacteriologists for solving some of our clinical difficulties by demonstrating that not all false membranes are diphtherial. The streptococci, for example, seem capable of giving rise to pseudo-membranous deposit. The exudation occasionally present in early scarlatinal throats, which are extremely red and swollen, is not generally true diphtheria, and this harmonises with what is found clinically, that the exudation seldom spreads, and that paralysis does not supervene.

The manifest alteration after the use of antitoxin, even in a most unfavourable and ultimately fatal case, is convincing enough to an informed person that we have here a fundamental remedy of enormous potency.

When, within forty-eight hours, we see a young subject with malignant diphtheria, accompanied by secondary infections which are on the verge of setting up septicæmia, so far relieved after the use of the remedy that the glands are reduced in size, the cellular tumefaction of the neck is lessened, the membranous exudation is arrested, and begins to separate at the edges, the tongue is more moist, and the general state ameliorated, we know that something has been done to control the disease processes with which no previous treatment with which we were acquainted was in the least degree comparable.

Furthermore, in cases in which tracheotomy has to be performed, not only are the mortality statistics improved, but we see for ourselves that the membrane formation ceases to spread, and the tube, which has formidable disadvantages of its own, can be withdrawn much sooner, and the risks of ulceration and stenosis can be thereby lessened.

Since the introduction of the antitoxin, the urgency of local applications to the fauces has become lessened to a marked extent. We are told that antitoxin only neutralises the toxin, but does not destroy the bacilli themselves. A weak mercurial solution which attacks the bacilli, though it coagulates the albumen, and an alkaline solution which favours the solution of the membrane, seem to be all that are needed. By too much zeal in local applications, we interfere with the protective action of the phagocytes, and the old corrosive applications are entirely ruled out.

With continued experience the limitations of antitoxin are becoming more and more clearly understood. A careful man seeks the assistance of the bacteriologist in every doubtful case, but does not wait for his report, for he knows that the certainty of success depends on the remedy being introduced early, say within the first three days, and that the risks of its employment are insignificant. The existence of secondary infections makes him far more anxious, and he feels compelled to warn the friends on that account, but it does not prevent his applying the diphtheria antitoxin even in very grave cases. Experience does not seem to support the concurrent use of antistreptococcus serum.

TETANUS.

While the diphtheria antitoxin treatment is in every way the most satisfactory of all the serum methods, the other members of this group of therapeutic measures are full of suggestion, and it is worth while briefly to consider a few of them.

Thus, with regard to the tetanus antitoxin, although the experiments on immunisation of animals have not furnished us with a successful method of dealing with the severe and acute cases of human tetanus, yet some benefit has been gained in the chronic forms.

OTHER EXAMPLES OF SPECIFIC REMEDIES.

In the other examples of this kind of treatment we have to depend on very incomplete data. For example, in rabies we are still ignorant as to the micro-organism, which we are none the less convinced is the cause of the disease. But the knowledge that the poison is lodged in the cerebro-spinal tissues has led, in the hands of Pasteur and his pupils, to the most fruitful results. The working hypothesis that in the dried spinal cord of an animal that has died of rabies the micro-organisms are destroyed, but that the immunising substances remain active, seems to have been justified by experiments based upon it and by its applications.

There surely can be no doubt of the prophylactic value of Pasteur's methods so far as those who have been bitten by rabid animals are concerned, although no beneficial effects follow their employment in the developed disease. But when a complete analysis of the life history of the organism has been attained, we may fairly look for still greater results in the therapeutics of this disease.

Is it unreasonable to suggest the same thing with respect to the great triumph of English protective medicine, namely, vaccination? One of the best results of the recent Royal Commission was that it gave the *coup de grace* to the easy optimism of those of us who considered that there was finality in what had been already accomplished, and that nothing more was needed than to continue on the old lines.

But the most recent methods of preparation with the carefully-regulated glycerination, and the getting rid of so much of the secondary infection, for which we are indebted to Copeman, mark an enormous advance in the practical application of vaccination.

Who can doubt that there are still further triumphs in store for us when the organism has been discovered and its natural history has been completely worked out?

Of plague, cholera, and typhoid I will not speak, for the inoculation methods are still *sub judice*.

With respect to the employment of antistreptococcus serum we are met by the most various testimony. Some cases of erysipelas and puerperal fever, and some of those most desperate cases of acute septic mischief following on infections from necropsies, have been strikingly benefited by the use of injections of the serum. Some cases of infective endocarditis appear to have improved, but a great many others have shown no response whatever.

It would appear that although streptococcus is the organism common to many forms of septicæmia, and although morphologically no differences can be established, according to the lesion from which it is derived, that there must be many different strains, and that the serum of an animal that has been immunised from one strain will not necessarily prove beneficial to an animal subject of another strain. Meanwhile it would seem that in any case of formidable septicæmia, when there is substantial reason to doubt whether the patient can cope with it successfully, we are not justified in withholding the use of antistreptococcus serum, which should be recently prepared.

THE TREATMENT OF TUBERCULOSIS IN THE LIGHT OF MODERN DISCOVERIES.

Koch's great discovery of the tubercle bacillus in

1882 has been so far-reaching and comprehensive that the simplification which it has brought about in our knowledge and in the mode of grouping of a great body of facts seems almost incredible. The most important outcome was that it confirmed the doctrine that tubercle should be placed among the chronic infections and so helped us to realise, in some sense, the kind of enemy with which we had to deal.

The importance of the tuberculin injection as a test for the tuberculous lesions in cattle seems to be very great indeed, but the justifiability of the employment of this test in the human subject for the determination of a doubtful lesion is, I think, open to question, although it has been extensively employed without proof of harmful effect.

Let us now consider in detail what we have learned from recent sanatorium experience in our time. First, we have learned the value of hyperaëration and of establishing tolerance to cold and to exposure to variations of temperature. The value of hyperaëration is not summed up in its affording more effective oxygenation to the lungs, parts of which are *hors de combat*, though that counts for a great deal. The access of free air is also a natural and wholesome stimulus to the nervous system. It increases the appetite and lessens the languor and exhaustion of a chronic febrile disease which the still, warm air of the old sick-room did nothing to relieve. The getting rid of the liability to catarrhs of the upper passages by free exposure to pure, fresh air had been known to us apart from phthisis, if we had only had the sense to apply it, and the enormous difference between sitting in the open and sitting in a draught was an old story which we ought to have remembered. The daily exposure to free, cool air has also been shown to have a direct benefit in lessening pyrexia, diminishing sweating, and improving sleep. And can we exaggerate the value of the immeasurably greater intake of direct sunshine which this treatment ensures as compared with any ordinary mode of life?

With regard to the employment of exercise, the time when it is taken, and the exact amount of it, the sanatorium experience has shown us that the most important therapeutic indications depend on the careful record of temperature.

With regard to food, we find that the exaggerated fastidiousness which is so hard to deal with in phthisis is less of a difficulty under sanatorium treatment than under ordinary conditions; that the number of patients who are unable to assimilate milk is exceedingly small; and, finally, that the enforcement of large mixed meals, at any rate for a period, is on the whole justified by the results of chemical investigation and of the actual well-being of the patients.

It is also clear that to meet the full needs of the poor there ought to be some form of special hospital provision made for incurable and rapidly advancing cases of phthisis. These are certainly not suitable for the sanatorium, and it is unfair to frustrate the true work of the sanatorium by sending such patients thither.

On the other hand, with our present arrangements of general hospital and infirmary wards, the contiguity of cases of acute and curable disease with those of advanced phthisis in which there is copious expectoration is always an anxious matter, even when precautions are taken.

First as to the prevention of infection, voluntary notification has been established in Manchester and elsewhere, with very good advantage. There seems to be very little difficulty in securing disinfection of rooms after a fatal case has occurred in the abodes of the poor, and experience would seem to show that, with tact, notification of phthisis during life may be followed by sanitary inspection, and by such useful guidance as to ventilation, cleanliness, and disposal of sputum.

With regard to the relation of human tuberculosis to that of the lower animals, Koch's remarkable deliverance has no doubt led to much searching of heart, but we must possess our souls in patience and wait for the results of further and more exhaustive investigation.

Meanwhile, let us do all we can to prevent the relaxation of the hard-earned sanitary regulations which have been obtained for the protection of the community in respect to cattle. There can be no doubt of the wrong done by allowing milk to be supplied from a cow with a tuberculous udder; and the value of the tuberculin test for revealing this disease has been definitely proved. The instruction to our patients to scald their milk should be given universally, although we may condemn the prolonged and repeated sterilisations at high temperatures which have lately become fashionable.

But I must confess that for my own part I have not yet been convinced that the abdominal tuberculosis of young children is in any large amount the result of infection pure and simple from tuberculous milk. Human tuberculosis absolutely limited to the alimentary canal and to the mesenteric glands is not a very common disease. I believe that for young as well as old the entrance of tubercle is in far greater proportion by the respiratory tract, and that its resting place is in the bronchial glands and the lung alveoli, and that in a large number of cases the infection of the mesenteric glands is a secondary one or part of the general infection. Also the habit of swallowing the sputum, which is so constant in children, ought to be taken into account in the consideration of the production of intestinal and mesenteric tubercle. Three colleagues of mine at the Children's Hospital, Great Ormond Street, who had held the post of pathologist there, namely, Dr. Colman, Dr. Batten, and Dr. Still, have published the results of their investigations, and these all point in the same direction.

The carefully-recorded observations of Dr. Carr, Dr. Guthrie, and Dr. Northrupp likewise show the great preponderance of bronchial glands as the common site of tuberculous lesions in children.

The most important antecedent and predisposing conditions for tuberculosis among the children of the poor are measles and whooping-cough, and the close stuffy rooms in which they are treated and in which their convalescence takes place.

The response of children to open-air treatment is, if anything, more striking than that of adults, and I believe that it will be found that they are more tolerant of exposure to wind than adults are.

The Differentiation of Meningitis.

Bacteriology has done a great deal towards the elucidation of the somewhat confused groups of meningitis. Setting aside the septic cases which arise in connection with otitis and bone disease and injury, as well as those severally dependent upon syphilis and tubercle, there remain:

1. The epidemic cerebro-spinal fever, in which the characteristic organism is the diplococcus intracellularis.
2. The rapidly acute forms, often vertical, but sometimes cerebro-spinal, which are associated with pneumonia, empyema, and ulcerative endocarditis, in which the pneumococcus is the characteristic organism and—
3. The sporadic subacute form, especially found among young children, often limited to the posterior region of the base of the brain, but sometimes also spinal, which is usually unaccompanied by any visceral disease whatever. In this form Dr. Still has isolated a diplococcus, allied to that of the cerebro-spinal fever, but with some definite differences.

There is scarcely any group of diseases in which the resources of therapeutics have been so discouraging. It is true that in the first and third of these forms there have been a certain number of recoveries, and, although for my part I would not relinquish the use of mercury, yet it seems doubtful whether drugs have played any important part in the recovery of the successful cases. Although lumbar puncture and drainage from the cervico-occipital region have temporarily relieved pressure symptoms, they cannot as yet be strongly urged as curative measures.

May we not reasonably hope that serum therapeutics will one day find some tangible success in this group of intractable diseases?

The late Dr. Washbourn, whose premature loss we all lament, had succeeded in making an antipneumococcus serum, and it has also been prepared and used in Italy. But the results hitherto obtained, so far as pneumonia is concerned, are inconclusive. I am not aware that there is evidence as to its effect in the form of meningitis depending on the pneumococcus.

HOW ADVANCE MAY BE MADE IN THE FUTURE.

Hitherto we have stood on more or less solid bases of established fact, though there have been many gaps in our knowledge, but it would be interesting to forecast a few of the probable directions in which research in the forthcoming generation is pretty certain to add to the common stores.

With regard to nervous diseases it seems almost certain that some of the acute types will be brought still more into line with the specific fevers. Anterior poliomyelitis, for example, which occasionally affects two or three members of a family almost simultaneously, and which shows some striking relationships to the exanthemata, will almost certainly prove to be an acute infective disease.

The nervous sequelæ and complications of the exanthemata are a mine of clinical wealth and suggestion, for they point not only to disseminated foci of cerebral and spinal hyperæmia and extravasation, but also to later changes, at first insidious but sometimes far-reaching, dependent on the dissemination of the toxic products of bacillary growth.

The great group of peripheral neuritis, towards the elucidation of which we are pre-eminently indebted to the Manchester School (and notably so within the last year), is indeed a meeting-place for many ætiological factors, but it is especially suggestive as showing the parallel effects produced by toxins which are the outcome of bacillary activity, and by inorganic and organic material introduced by way of the alimentary tract, and perhaps by poisonous products elaborated in the body itself by faulty metabolism.

Can there be any reasonable doubt that we are on the eve of a fuller elucidation of cancer, and that when the history of the organism which we suspect to be behind it has been learned, then the fragmentary and isolated pieces of knowledge which have been painfully and slowly acquired during past generations will slip into their proper places like the blocks in the puzzle of a child? But if the history of previous discoveries in our science goes for anything, this, again, will be an instance of the convergence of work of experimental pathology, biology, and chemistry, and of clinical medicine and surgery in their widest connotations.

Gentlemen, I have finished my task. I have tried to drive home the thesis that the advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease. I have given various instances in support of this thesis, and others could be given. If we are agreed, what is our duty arising out of this conviction? Surely that we ought to do all that in us lies to maintain, to develop, and to defend experimental research in alliance with clinical work.

Our countrymen are wakening from their complacency, and beginning to realise that in our great industries it is imperative, if we would keep our place, that well-directed scientific research should be liberally and steadily maintained. And shall it be said that in the care for the life and health of the community, the noblest and most precious of all industries, we are to be left crippled and poverty-stricken by the absence of suitable equipment?

Let us fain hope that the day may come when to the other beneficent functions of this association there may be added some form of systematised, continuous, and widespread local organisation for the scientific study of the problems of disease.

THE sum of £27,377 has just been awarded to the authorities of the London Hospital for a strip of land required by the London School Board for the erection of a school. The original claim by the hospital was for £38,000.

CARCINOMA IN WOMEN:
CHIEFLY IN ITS CLINICAL ASPECTS. (a)

Eadem orationis virtus atque unguenti, nam et male affectos nos juvat, et bene habentes oblectat.—*Demophilus.*

By
WILLIAM JAPP SINCLAIR, M.D.,
Professor of Obstetrics in the Owens College, Manchester.

APOLOGY AND JUSTIFICATION.

IT is generally believed that carcinoma of the sexual organs of women is as cancer occurring in men, and to this extent, therefore, the subject is not one of obstetric medicine pure and simple. But malignant disease has a tendency to affect certain organs in women to an extent and with a relative frequency unknown in the other sex; and the clinical facts in the typical cases of cancer of the uterus make up a *tout ensemble*, an association of syndromata, a personality of the disease, that distinguish it from the malignant disease of any other organ.

If carcinoma of the uterus be the same disease as cancer in general, may not this individuality or personality of the malady make it the key to the situation? The frequency with which the disease occurs in a medical practice, the comparative similarity pervading the cases amidst individual differences, the facility with which operations can be performed and therapeutic agents employed, the possibility of careful clinical investigation and observation of cases in which the disease recurs, and of cases immune from recurrence, are all circumstances which attract attention to this special form of malignant disease, render it a comparatively easy subject for inductive reasoning, and therefore make of it perhaps the most promising field for clinical research.

PATHOLOGY AND CLINICAL GYNÆCOLOGY.

There is a general and a special aspect of the subject which we may examine in proportions suitable to the occasion: (1) The investigation of the ætiology and pathology of cancer in general; and (2) the consideration of cancer of the uterus in particular. The practical gynæcologist may ask: What have investigations and researches into the ætiology and pathology of cancer of the uterus done for clinical gynæcology? The answer must be guarded, at this stage at least. A late distinguished gynæcologist once said in his haste that a knowledge of anatomy was positively misleading with regard to the surgery of the pelvis. It can hardly be alleged that pathology has been misleading to the gynæcologist, for he has never trusted to its guidance. "Men are wiser than their creeds"; they hold pious opinions in religion which, fortunately, they never put into practice. They affect to entertain, because they have never questioned, certain theoretical tenets in medical science, but these beliefs do not in any way modify or injure their practice. If we could effectively pass in review the old pathology and the new, and estimate their practical results, we should, I am convinced, be greatly impressed with the need for clinical gynæcology saving itself by scientific clinical work.

THE NEW PATHOLOGY.

It would take us too far away and far too long a time from the clinical consideration of the subject to go into detail on the newer ætiology and pathology of cancer in general, and the disease as it affects the female sexual organs in particular. But it may be as well, for the sake of completeness, and on account of its bearings on the practice of to-day, to glance at the chief features of the more recent research and controversy.

Is the cause of malignant disease a vegetable parasite or blastomycete as suggested by Russell ten or twelve years ago, and worked out by San Felice and many others?

Are the "cancer bodies" animal parasites? a theory maintained by Gaylord, and supported by much persevering and ingenious observation and experiment.

Is it an infectious disease most nearly resembling tubercle and syphilis? or is the cause still entirely unknown or merely guessed at as possibly the result of local or general changes in the nervous system governing the growth, the nutrition, and involution of organs and tissues?

(a) Abstract of the Address in Obstetrics at the Annual Meeting of the British Medical Association at Manchester, July-August, 1902.

It would be impossible within my limits, and with the objects in view, to discuss all this in detail, but glance at the work of one or two individuals and inquire what relation their results have to the clinical observation and the treatment of disease.

Leopold of Dresden, after many years of observation and experiment, placed the results of his labours before the profession at the International Congress held at Paris in 1900, and he returned again to the subject at the Congress of German Gynæcologists held at Giessen last year. His conclusions amount to this: That blastomycetes may be the cause of malignant new growths in man; that they may convey the disease by inoculation from man to animals, producing exactly similar new growths which are fatal to the animals affected. Among his experiments Leopold mentions the implantation into a rat of tissue from carcinoma of the ovary. The animal died in sixty-one days from a tumour the size of a walnut, which was found to be an adeno-sarcoma.

It will thus be seen that Leopold, like some other experimenters, in order to prove his theories must give up the distinction between carcinoma and sarcoma. This may be right, and a step towards truth and simplicity, or it may have been accepted by the author under stress of circumstances like the poet succumbing to the inexorable demands of rhyme at the expense of the sense, or it may only imply, which is most probable of all and certainly true, that it is not always possible to distinguish between carcinoma and sarcoma by the aid of the microscope alone.

In referring to this subject in a recent discussion, Menge expressed the opinion that such experiments produce merely granulation tissue with giant-cells, and he further says: "If Leopold holds to his belief in the specific nature of his cancer-producers, he must admit the identity of carcinoma and sarcoma."

W. A. Freund's opinion of such experiments may be inferred from his oracular advice when concluding his appreciation of Leopold's work: "Wait and see." (*Abwarten!*)

With regard to the parasitic theory of cancer, some very confident statements as to progress in discovering the causation come to us from America. At the last meeting of the American Gynæcological Society, one of the speakers gave typical expression to our vague hopes and aspirations. In the course of a paper on Hysterectomy for Uterine Cancer, he said: "Are we not justified in the hope that the so-called parasitic theory of the origin of cancer may evolve something? The solution of the question depends upon the bacteriologist and pathologist. We can but look upon the subject with some seriousness when the great State of New York has considered it of sufficient importance to establish a pathological laboratory for the study of the ætiology of cancer. Dr. Gaylord, of that institution, has reported that he has found the protozoon." During the discussion which followed, Dr. Matthew D. Mann, Professor of Gynæcology in the University of Buffalo, said: "I know the profession is not ready yet to accept the evidence of what has been done in Buffalo, but, personally, I feel quite convinced that in the State Laboratory the cause of cancer has been discovered."

Cancer of the Uterus, not as a Growth but as a Disease.

We search, then, in vain through the recent manuals of gynæcology, and even of pathology and the records of pathological investigation, for any hint of progress in the evolution of an ætiology of malignant disease of the internal sexual organs of women. Of histology there is enough and to spare, but of pathology in the narrower sense there is but little to arrest attention, much less to satisfy; and there is absolutely nothing to indicate an advance from the position of a former generation of pathologists. The nomenclature is new—the thoughts and principles are old. There would, in fact, be a certain amount of truth in the allegation that the diligent pursuit of the histology of malignant growths and other tumours has distracted the attention, the activities, and the energy, to say nothing of the intellectual force, which might have led to a true pathology of cancer of the uterus by fixing the attention upon structure, growth, and extension in relation to clinical phenomena. We have heard too much of cancer as neoplasm, too little of it as a disease. If, now, we set aside all considerations of the ætiology and pathology of cancer of the uterus, and keep in mind only the clinical aspects of the disease, we see much ground for congratulation on the achievements of the last quarter of a century. The clinical work has been wholly surgical. What is not surgical is futile—it is hardly knowledge.

What has been Accomplished.

It is nearly thirty years since, as house surgeon to a gynæcologist of great local repute, I had every opportunity of observing the treatment of cancer of the uterus, a disease which when a student I had never once seen diagnosed by a clinical teacher. The routine method was to clear away some of the *débris* of tissue from the invaded portion of the cervix, and apply a certain liquid which had at the time a more general application in the treatment of certain diseases of the skin. The treatment was painful, and that was all. No patient was kept in the hospital to die, and I need hardly say that no one received appreciable benefit. Next came the period of bromum and other specifics equally futile.

A few years later I had the opportunity of witnessing the operations by the galvanic écraseur of the late Professor Carl Braum von Fernwald, in the Vienna General Hospital. He obtained a wonderful degree of success in arresting for years, and sometimes permanently, the progress of the disease by removing the vaginal portion of the uterus when that was the only part involved. Next, Schroeder of Berlin practised and advocated the supra-vaginal amputation of the cervix. The practice has been continued to the present time by some of Schroeder's pupils, notably by Hofmeier and Winter.

Next came the period of progress with the operation of total extirpation. Many hesitated to attempt it owing to the immediate danger. But the technique rapidly improved, and it soon became the generally-accepted operation, because it afforded the best grounds for hope of conferring prolonged benefit or definitely curing the patient. Whatever we may think of the remote results of our surgical work, no one who knows the history can deny that the reduction in the immediate mortality from this operation marks one of the greatest triumphs of modern surgery.

Vaginal hysterectomy, when the disease is confined to the uterus, is not now more dangerous than an ordinary ovariotomy. The mortality, which at one time was 30 per cent., has now sunk to 3 or 5 or 7 per cent., according to the extent of the disease and the concomitant complications or derangements of health.

In recent years there has been a wave of depression passing over the gynæcological world on account of the unfavourable remote results of vaginal hysterectomy for cancer, and the most optimistic will admit that there has not been much ground for satisfaction. At a recent congress of American gynæcologists one of the members said: "There are some men who claim for total extirpation of the uterus the happiest results. . . Other men have looked upon the matter with utter hopelessness. . . . I am sorry to say that I have brought myself among the latter class from bitter experience." This opinion is very far indeed from being held of that majority of operators who are not extremists towards either optimism or pessimism.

We may select examples from every country in Christendom, which now includes America, and the lessons taught by all are the same.

Winter reports from Berlin 308 operations, with a mortality of 5 per cent. Recurrence took place in nearly 70 within five years, and there were nearly 30 per cent. of permanent cures. Of the cases in which the operation could be effected in sound tissue the proportion of cures was 33 per cent. Winter remarks on the frequency of recurrence in the cicatrix.

As representatives of Italy we may quote Spinelli and Mangiagalli. The former reports 41 operations, with a primary mortality of 2·4 per cent., but the "cures" were only 8·9 per cent. Mangiagalli had 127 cases, with a mortality of 8·6. Only seventeen patients were free from recurrence after three years. In his cases recurrence was *always* in the cicatrix.

In this country Lewers traced the history of forty cases operated on radically per vaginam with a primary mortality of 7 per cent. There was freedom from recurrence in 27·5 per cent. from two to seven years. In eleven cases of cancer of the body five of the patients were well from four to seven years after operation.

These illustrations of work done might be multiplied to an indefinite extent, but enough has been set down to support the statement that there is ground for encouragement, not for depression, much less despair, in the history of vaginal hysterectomy for cancer.

To our resources that will enhance the value of surgical interference in the future there is, in my opinion, no more valuable contribution than the improvement in technique introduced by the late Professor Schuchardt of Stettin.

The most remarkable figures of all are those given by Schuchardt as the results of the paravaginal operation. The best results before were those of Leopold in Dresden, who, with an operability of 20·4 per cent., had 50 per cent. of conventional "cures." Schuchardt raised the operability to 61 per cent. and had conventional cures to the extent of 40 per cent. In easy cases he had the astonishing result of 80 per cent. of cures.

REACTION.

One of the results of the depression arising from the recognition of the unfavourable remote results of vaginal hysterectomy has been a rush, especially in Germany, to the extreme verge of the practical in dissecting out not only the internal sexual organs but the whole of the lymphatics and cellular tissue of the pelvis. This has been declared to be justified by the belief that better remote results would be obtained than by vaginal hysterectomy.

From a careful and laborious attempt to keep up with the record of proceedings, I have no hesitation in saying that a large portion of the extended radical abdominal hysterectomies for cancer are murderous vivisections, which nothing hitherto advanced in their support appears to palliate, much less to justify. Most of the cases recorded have been too far advanced for any operation, however radical.

There appears at the present time to be no visible limit to operations for cancer in the judgment of some of our contemporaries. The title of one very recent contribution to a gynæcological journal must suffice for calling attention to *Fortschritt* in the direction of vivisection: "Simultaneous occurrence of cancer of the uterus and of the stomach—abdominal total extirpation of the uterus, gastrectomy with gastrojejunostomy."

THE FUTURE OF TREATMENT AND THE AIMS OF CLINICAL RESEARCH.

Among the preliminary considerations which call for attention comes the question: Is cancer of the uterus on the increase? My own firm conviction for a long time has been that it is not, in spite of all allegations to the contrary.

If, as I firmly believe, cancer of the cervix is a different disease from cancer of the body, and is a morbus miseriæ like osteomalacia, leprosy, and pellagra, it is bound to decrease as the social condition, the physical well-being, the freedom from worries, and the consequent comparative happiness of the people improve.

OUR HOPES OF IMMEDIATE AMELIORATION REST, THEREFORE, ON SURGERY.

We must rely not on the extension of operative procedures into the brilliance of vivisections, but on the united efforts of all concerned to bring the cases under surgical treatment at the earliest possible stage.

We labour at present under considerable disabilities:

1. The patients are not so well trained and disciplined as German and other women in Continental Europe. They naturally hesitate when they think of going to a doctor to tell of their symptoms, and they neglect the most ominous symptoms with a light heart because they suffer no pain. The consequence is that as a rule our cancer patients consult the doctor when it is clearly too late to do any operation justifying the hope of cure, or even prolonged immunity; and many cases seek advice for the first time only when it is almost too late to palliate.

2. This is clearly the most important of the many diseases regarding which the interest of the general practitioner in the subject and his influence with his patients are our chief ground for hope of ameliorations. To him the patient first appeals, and consequently on him depends whether steps shall be taken promptly or otherwise to bring the best resources of medical science to bear on the individual case. If I might venture a criticism, my own experience would suggest that all are not sufficiently insistent on physical examination, even when there is *primâ facie* evidence that the cause of the symptoms is malignant disease.

3. Among the causes which lead to late diagnosis of malignant disease of the uterus—partly by leading the patients to present themselves late, and partly to the postponement of examination—is the prevalent superstition with regard to a "climateric hæmorrhage." I have no hesitation in saying with entire conviction that "climateric hæmorrhage" is, like the collective term "cancer," one of the inherited burdens which we drag along with us to our hindrance and grievous detriment. Apart from pathological conditions usually diagnosable, there is no such phenomenon in nature.

4. Another popular delusion which stands in the way of early diagnosis of cancer of the uterus is the belief that pain is an invariable symptom of cancer. When the sufferer from cancer begins to complain of pain, we all know now that the disease is too far advanced for radical treatment.

What has been implied in all that I have said I now wish to state explicitly for what it is worth. It is my firm conviction that the secret of cancer in general will be discovered, if ever, by the study of carcinoma of the uterus, and that the means will be exact clinical observation, followed perhaps, and corroborated by, experimental research.

The microtome and the cultivation tube and experimental implantation have had their day; they need not cease to be, but they should find their proper place in our system of research. We may get at the causes of malignant disease, as far as we understand the causes of things, by exact clinical observation; but the specific remedy or the system of therapeutics will come, in all probability, as a stroke of empiricism from an individual working for the sake of knowledge. It might be argued that the pathology and serum treatment of tuberculous disease and diphtheria are examples to the contrary, but there appears to be hardly any analogy between the genuinely infectious diseases and the phenomena of cancer.

Cancer is infectious to the individual already affected with cancer, but to no other. The phenomena of rapid recurrence in the cicatrix after operation, owing to contact of the fresh wound with cancerous matter, points to an early cancerous condition of the system, an entirely different matter from the late cancerous cachexia.

APPLICATION OF LOGICAL METHODS.

If we are ever to arrive at the causation of carcinoma of the uterus we must teach it by the rigid application of logical methods of induction to clinical work. We are already in possession of certain facts established clinically with regard to cancer of the body and cancer of the cervix, and the extent to which they are dissimilar. We might begin with carcinoma of the cervix. It is a diseased condition, with antecedents and characteristics almost entirely its own. Its characters fit it specially for clinical observation and the application of logical methods of induction.

"If two or more instances of a phenomenon under investigation have only one circumstance in common, that circumstance is the cause of the phenomenon." The application of this method of agreement would require very patient notetaking, according to a rubric containing every antecedent circumstance which has ever been suggested as the cause, or connected with the cause, of the disease. After a time it would be seen what was the invariable antecedent, if any, in every case. If there was no invariable antecedent of the phenomena of the disease over a considerable series of cases, then the rubric would have to be strengthened by new possible antecedents, while the obviously irrelevant could be abandoned. By the antecedent circumstances, I mean such facts as heredity, previous illnesses, especially contagious diseases, social circumstances, marriage, childbearing, puerperal ailments, menstruation, lactation, and an indefinite variety of others. One of the earliest results of this method would probably be the differentiation of the varieties of malignant disease of the uterus, just as clinical work alone established the differences between the fevers in the past. We would learn which clinical varieties most readily recurred, where the recurrences commenced, and how the last state of the operation case after recurrence compared with the case in which the disease had been allowed to run its course unaffected by treatment. Facts would be proved, fables disproved. Conclusions formed would become opinions, not individual impressions.

Conclusion.

Running through all I have said and implied, in some apparent digressions has been an effort to attract attention (as far as anything I may say can do so) to the dignity and the effectiveness of exact scientific clinical methods of observation. To do so it seemed necessary to contrast the futility of much of the labours of the past in order to establish the ætiology and true pathology of cancer. All honest and enlightened human effort should be welcomed; I depreciate none. But chiefly is my hope fixed on the fact that in such research as I have been suggesting every member of the medical profession engaged in general practice could co-operate in genuinely scientific work with those whose daily occupation was of a special character.

I shall not parody the language of the great German authority upon whom I have so largely drawn, and speak of a Promised Land: I shall content myself with saying that my earnest hope and desire is this: that some of our younger men with more energy, better opportunity, starting on a higher level of knowledge, will professedly take up this great enterprise and see whether by calm, industrious, and enlightened clinical observation, alone or collectively, they can find out for mankind the cause and the remedy for this mysterious and dreadful malady.

DILATATION OF THE STOMACH.

By T. CLIFFORD ALLBUTT, M.D.,
F.R.C.P., F.R.S.,

Regius Professor of Physic in the University of Cambridge,
Physician to Addenbrooke's Hospital, &c.

In opening a discussion on this subject at the Manchester meeting of the British Medical Association, Dr. Allbutt confined his remarks chiefly to the atonic or non-obstructive dilatations of the stomach, as the obstructive dilatations were, comparatively speaking, well understood. Atony and atonic dilatation had not received the attention they deserved, atonic dilatation, indeed, being neglected by some physicians, and by a few even denied. Acute dilatation of the stomach he was disposed to attribute to compression of the gut by the distended viscus itself about the junction of the duodenum and jejunum. "The stomach," he said, "is supported more firmly at the cardiac than at the pyloric end; and in any case its mean position is more vertical than is generally supposed, especially when empty. In estimating atonic dilatation, especially in its lesser degrees, the area of the cardiac moiety is therefore to be carefully observed. The stomach may drop as a whole into the mid-abdomen or hypogastrium, and this independently of more general enteroptosis. Gastroptosis is not necessarily attended with dilatation. In this case the stomach assumes a wallet shape, the cardiac and pyloric orifices approaching each other; or if the pyloric end slip more than the cardiac the position of the organ is more vertical and to the left. In this latter case the more muscular pyloric moiety is apt to become dilated by the gravitation of retained contents. The relation of gastritis to dilatation of the stomach is little understood. It would seem that excess of hydrochloric acid is not necessarily, or perhaps usually, in its earlier stages a consequence of gastritis; it may rather be the cause of it. During life the presence or extent of gastritis is often assumed on very slender grounds, and even our post-mortem knowledge of it leaves much to be desired. Relaxation of the stomach, due primarily to muscular failure, and therefore appearing first in the pouch and fundus, may depend upon toxic causes or mere atony. Such gastric distension, advancing to dilatation, not uncommonly retards convalescence from such diseases as typhoid fever and rheumatic fever. When the condition follows slow digestion with fermentation, anæmia, or mere inanition, the muscular failure is primary. That spasm of the pylorus may cause dilatation of the stomach, as, for example, in ulcer, hyperchlorhydria, or lumpy contents of the stomach, seems not improbable. Such morbid action is consistent with what we know of other sphincters; but atonic dilatations rarely seem big enough to be due to a permanent spasmodic contraction of the pylorus; nor is the muscular coat, as we should expect, hypertrophied. In atonic dilatation peristalsis does not become visible. That the nervous system may be concerned in paresis of the stomach seems likely enough; not only that continuously depressing causes may act in this way, but that sudden and grave mental shock may be quickly followed by considerable atonic dilatation of the organ. The effect of alcohol, in so far as it may be a cause of dilatation, may act directly as a poison to the muscular fibre or indirectly by extension of inflammation outwards. Atonic dilatation of the stomach is no rare consequence of exhaustion by excessive athletic exertion or mental stress, especially in young people of delicate constitution. Dilatation of the stomach is far from being rare in little children and infants; in them it often comes on acutely, but if the condition be understood it is readily relieved by emetic or the tube. The symptoms of atonic dilatation, to an observer not forewarned, are often indefinite, if not misleading. There may be little or no loss of appetite or dyspepsia; in an early stage of the disorder food often relieves a sense of sinking. Vertigo, sleeplessness, heaviness, lassitude and fatigue, and mental depression may divert attention to the nervous system. Flatulence, indeed, is rarely absent, but the tongue may be clean, vomiting slight or absent, the bowels constipated or the stools occasionally lienteric. The heart is apt to flutter or to intermit, and the abdominal aorta to throb. In extremer cases the pulse falls in volume and pressure, the hands become chilly, the nails livid, and the face thin, drawn, and sallow. By physical signs we may determine the size and position of the stomach. In thin persons gastroptosis is not difficult to ascertain (in well-nourished persons it never seems to occur), and it is for the most part curable by rest, massage, and better nutrition. When, as is usual, the dilated stomach occupies (approximately) its normal position detection of the disorder by physical signs will, generally speaking, be easy. Under ordinary circumstances peristalsis is never visible, as in obstructive dilatation, and the signs of distension are chiefly notable to the left of the middle line and under the lower ribs; the ballooned stomach is apt to push up the diaphragm and to encroach upon the thorax. The area of resonance may rise to the fifth or fourth rib and may extend to the posterior axillary line. Such a stomach often accompanies diseases of the heart and plays a large part in the patient's distress. Physical examination must be made at various periods of digestion and when the stomach ought to be empty. In health the stomach after a meal should contract upon its contents, when an area of dulness rather than of resonance will become apparent. Even in acute indigestion there is a considerable grip of these contents, a grip often attended with stomach-ache, but in atony, with or without static dilatation, an area of resonance at the cardiac end will be found almost immediately after a meal; even four or five hours after a meal the vault remains high and, behaving capriciously under gaseous influences, at no time does it contract in any regular periods. Thus the pyloric moiety, in its turn unable to withstand the gravitation of its contents, increases from its comparatively small transverse diameter until the stomach as a whole may assume a uniform, thick, sausage shape, the upper outline of which may include the nipple and the lower the navel. Strangulation by sharp flexure of the pyloro-duodenal portion may occur in particular cases but such cases are not so common as we suppose. Dropped kidney is often rather in association with atonic dilatation or gastroptosis than a cause of them, though Sir William Bennett and Mr. Bidwell have incidentally relieved dilatation by fixation of a right kidney. Dilated colon may be mistaken for a dilated stomach, and in rare cases the error may be unavoidable; but in the vast majority of instances by discriminating percussion, even without intubation, these two organs may be distinguished. The stomach may no doubt be wholly concealed by the colon, but ordinarily some narrow area of stomach resonance can be obtained, when a difference of percussion-note, either in pitch or clang, can be made out. In difficult cases syphonage or insufflation may help us: Von Ziemssen recommended in such cases alternate inflation of colon and stomach. The tuning-fork, auscults-percussion, and coin-tapping, in my experience, add little or nothing to what careful percussion can reveal. In a healthy stomach no squelchy sounds should be obtainable; they are usually obtainable in atonic dilatation, but rarely amount to the succussion splash of obstructive dilatation. If before breakfast squelching can be obtained after the drinking of a tumbler or two of water we have to deal with a flabby and extended stomach. The use of the tube is of cardinal importance for diagnosis if not for treatment, but among private patients in England this method is resented, and makes but little way. The normal fasting stomach contains at least from 20 to 30 cubic centimetres of residual fluid, and may hold even 100, but quantities above 100 cubic centimetres are morbid. In the normal state this residuum should not contain any particles recognisable as remnants of food: seeds, grit, or fibre in vomit or stool should be carefully noted, and the date when they were swallowed ascertained. The larger the residuum and the more obvious the relics of food the worse the case. A considerable admixture of mucus may indicate the presence of gastritis. In atonic dilatation sarcinæ and torulæ are not usually found, lactic acid but rarely and in small quantity. The quantity of water accepted by the stomach gives us little information; individual tolerance is very variable, but in atonic dilatation the return of it is very feeble, or perhaps is obtained only by expression or syphonage. Illumination of the stomach from within is of little service. From radiography we may hope for some more information. Chemical tests for the delay of ingesta, such as salol or potassium iodide, may corroborate but cannot dictate a diagnosis. The treatment of atonic dilatation must largely depend upon the causation of the individual cases; particular symptoms will often indicate the means of their own palliation. Vertigo, often very severe, and lassitude after meals often depend upon distension of the stomach, and may be quickly relieved by careful regulation of diet and restriction of fluid at meals to the lowest quantity. In sleepless cases, besides these measures, hydrotherapy expertly carried out is often the more useful, as it takes the patient away from work and care into a bracing climate. In heart disease, after much disappointment in the use of specific remedies, the cure or relief of an atonic dilatation of the stomach may be attended with remarkably good effects. Such patients, under the guise of a light diet, will consume quantities of farinaceous puddings, often well sugared, which disengage gases readily. Thirty years ago I traced a state of anæmia and debility apt to appear in colliers and others engaged in similar work to dilatation of the stomach, a dilatation due to want of home meals and to the consumption of large quantities of liquid with heavy food rich in carbohydrates. Mastication must be carefully provided for and papain I have found to be a very useful aid in digestion. The abuse of corsets and belts must not be overlooked. In these cases rest not only after, but also before, meals is of importance. In some emaciated persons the full Weir-Mitchell system may be necessary, especially in gastroptosis; in all a long rest and change of air are of the first importance, nor should such persons on returning to their ordinary occupations expose themselves again to excessive stresses and other causes of exhaustion."

Therapeutic Notes.

By GEORGE FOY, M.D., F.R.C.S.
Surgeon to the Drumcondra Hospital, Dublin.

ETHYL BROMIDE.

Under its new name of bromethane, ethyl bromide is being used as a general anæsthetic for minor operations. It is a colourless liquid of a peculiar ethereal odour and taste; it was first prepared by Serullas in 1827, by gradually adding twelve parts of bromine to forty parts of alcohol and one part of phosphorus; it is now prepared by the interaction of ethyl hydro-oxide with phosphorus bromide.

The physiological action of the anæsthetic was discovered by the late Mr. Thomas Nunnelly, of Leeds, whose name is familiar to toxicologists for his experiments with strychnine in 1851.

Mr. Nunnelly introduced ethyl bromide in the Leeds Infirmary as a general anæsthetic. The great expense of its production caused him to discontinue its use, but in 1865 he brought its claims before the British Medical Association. Chisholm, of Baltimore, used it 3,000 times without one death. He found it useful in minor surgery, but if its use was protracted beyond a few minutes it produced nausea, vomiting, and heaviness. Marion Sims considered it unsuitable if the kidneys were at all diseased. Gilles (*Berlin Klin Woch.*, February, 1892) records its successful use in many thousands of cases, and quite recently Dr. A. Brown Kelly, of Glasgow, has used it successfully in minor operations on the nose and throat.

The unpleasant effects of the anæsthetic are, according to Naub, of Berne, due to impurities. An interesting account of the chemical characters of the preparation has recently been published in the *Pharmaceutical Journal* by Mr. Gilmour, who recommends the formula of the French "Codex" for the preparation of the chemical, and gives some good rules for its preservation and testing.

That it acts well as a general anæsthetic I have shown ("Anæsthetics: Ancient and Modern"), but that it is not without lethal properties is proven by Professor Pancoast's case. It may for minor operative work displace nitrous oxide, to which general surgeons never took kindly; but although it is more agreeable to inhale and requires no elaborate apparatus, it is not as safe and is almost as evanescent in its effects.

RHEUMATINE.

Under the fancy name rheumatine there is introduced a new remedy for rheumatism. It is an ester, ether quinci of acid salicylic, of which the formula is C_6H_4 OH, CO. O C_{20} H_{23} N_2 O. Since 1820, when Pelletier and Caventon discovered quinine, or rather since its introduction into practice by M. Maillot in 1832, attempts have been made to get rid of its bitter taste and its unpleasant effect of cinchonism, without lessening its valuable therapeutic properties. One of the most successful of these was the ester ethyl carbonic of quini of von Noorden; produced in 1896, and many other combinations followed, of which acetyl quinine, succinyl quinine, phosphoryl quinine, chlorcarbonyl quinine, and diquini carbonate; these were followed by combinations of quinine and acids of the aromatic series, and we got anisyl quinine, cinnamyl quinine, and ether benzylcarbonite of quinine. The latest outcome of this chemical industry is rheumatine or saloquinine, a neutral base-forming acid, almost tasteless, and said not to cause any unpleasant head noises. It occurs in asicular crystals, which are insoluble in water, but freely soluble in ether and alcohol. It is claimed for the drug that it has a specific value in the treatment of infectious diseases and as a febrifuge; it is even more efficacious in the treatment of nervous pains and neuralgias than quinine. In sciatica Overlach gives 30-grain doses on the patient's going to bed and repeats the dose during the night if the pain continues. In typhoid fever its effects in 30-grain doses night and morning are said to be very marked. On all rheumatic affections it exerts an analgesic and a pyretic action, particularly in the acute forms. Overlach gives it in 15-grain doses three times a day for four days, and then discontinues its use for twenty-four hours in acute rheumatism, and is much pleased with the results obtained. The drug has, however, some drawbacks; it makes a bulky powder, of which a large dose must be taken, and it is insoluble in water. Patients do not like large doses of bulky powders, neither do they care to swallow a thick fluid holding powder in suspension; to many, particularly women patients, capsules are not easily swallowed. These objections may be looked on as trivial, but nevertheless they are real and will interfere with the general use of rheumatine.

Clinical Records.

JESSOP HOSPITAL FOR WOMEN, SHEFFIELD.

Semi-Solid Multilocular Cystic Ovary.—Operation.—Recovery.

Under the Care of John W. Martin, M.D.,

Honorary Medical Officer, Jessop Hospital for Women, Sheffield.

Mary Ann S——, æt. 39, married, three children, the last, thirteen years of age. Admitted to the Jessop Hospital, May 7th, 1901, with a large abdominal tumour.

History.—Had an abortion twelve years before. Never pregnant since. She was quite regular down to August 1901, commencing on the third, and lasting for five days. In September, same year, had a slight show as if commencing, but it passed off; nothing afterwards. From puberty she had suffered from dysmenorrhœa, and the periods were always profuse, lasting seven or eight days; clots were passed.

In September she first noticed a small swelling in the hypogastrium, which steadily increased in size. At the time of admission the tumour was about the size of a six months' pregnancy. There was milk in the breasts, but this could always be expressed since the last pregnancy. Per vaginam the cervix felt decidedly softened. No movements could be felt, nor could fœtal heart-sounds be heard. She was seen in consultation by the other members of the staff. Although pregnancy was thought improbable, its possibility was considered, and a further period of waiting was advised. She was kept under observation until October 7th, when she was again admitted into the hospital. It was now thirteen months since her last period. The tumour had increased to the size of an eight months' pregnancy. She suffered very considerable discomfort and pain, shortness of breath when moving about, and was unable to discharge her household duties. The bowels were difficult to move, and there was dysuria. The sound was introduced and passed a little over two and a-half inches. Abdominal section was decided upon, and I operated upon October 18th, 1901. The case proved a difficult one, owing to the very numerous adhesions, which were difficult to deal with. The left ovary was the affected one, and was a large, semi-solid, multilocular cystic mass.

The patient made an excellent recovery; the wound healed by first intention. She was discharged from hospital November 9th, 1901. This case is another example of what one so often finds in such cases, *i e.*, those which give most trouble at the time of operation are often the most uneventful in their after-treatment and recovery.

As a contrast I recall to mind a case I had to deal with soon after I became connected with this hospital. The case was one of a very large unilocular ovarian cyst, complicated with pregnancy in the fourth month. The abdominal incision was very small, not more than an inch and a-half in length. The tumour simply bubbled out through the opening in a most marvellous manner; there was not a single adhesion; the pedicle was very small and easily secured. The whole operation occupied barely twenty minutes, and I looked for a rapid and uneventful recovery, but was doomed to disappointment.

Paresis of the bowels set in very shortly, the abdomen became enormously distended, diarrhœa and vomiting set in, and, in spite of all that could be done, the patient sank in a few days.

Special Article.

CHINESE SURGERY.

By John Knott, M.A., M.D.Univ.Dub., M.R.C.P., M.R.I.A.

As a corollary of the brief article on "Chinese Medicine" in the issue of The Medical Press and Circular for July 23rd, it has occurred to me that the publication of a few authentic items connected with the practice of the healing art in the vast "Dead Sea of Man" might not be unacceptable to some of its readers. My present data refer chiefly to the surgery rather than to the medicine of the "Celestials"; as the latter, I find, although fairly well described as "a simple farrago of nonsense and superstition," presents a startling family resemblance to that of our own forefathers, and, so far as I know, of every other family of the human race at a certain stage of its enlightenment.

Like gunpowder, printing, and various other of the most important means and methods which have from time to time been devised by the more restless members of the human race for the physical and mental improvement of the species, massage was known and systematically used in China for untold centuries before its recognition as a surgical procedure in the lands of modern Western civilisation. In one variety of its practice—that known to the native as *Koung-fou*, a special invention of the Taoist bonzes—there is superadded to the various frictional movements "martelage du muscle et de l'os." This operation is performed by means of small "maillets de bois," of which two kinds are employed: one of a foot in length and six inches in circumference, and the other six inches long and half an inch in diameter. There is another instrument specially devised for the application of rolling friction. It is "essentiellement constitué par deux roulettes accouplées sur le même axe, lequel est monté sur un manche de 20 à 25 centimetres de longueur." Dr. Matignon points out in this connection that his *confrère* Dr. Dudgeon, who has taken special pains in the investigation of the Chinese practice of massage, has clearly shown that many, many ages before Lind had established the principles of Swedish gymnastics, those Chinese priests were acquainted with the elements of "Kinésothérapie."

Dr. Matignon has utilised the opportunities afforded him in this domain by his residence in the Celestial Empire, as Attaché à la Légation de France à Pékin, to collect every available information regarding the present state of knowledge of the healing art in that vast and mysterious nation, and the modes of its application for the relief of physical ills. The conclusion at which he has arrived is, indeed, that which most of us would have anticipated: that China displays in her medical, as well as in her social, practices the unchangeable routine which hopelessly excludes improvement. Although, as in case of some of its mechanical artistic devices, it took a very early lead in a few directions, it assumed the fossil state in prehistoric times; and the net result offered in our own day is that "la médicine des Chinois est moins avancée, et surtout moins intelligente et moins scientifique que celle d' Hippocrate." Their medical literature is copious, and its bibliography has been studiously drawn up, but the whole contents consist of unreasoning commentaries on the works of a few old masters, whose texts, like those of other sacred volumes of Oriental literature, are far *too sacred* to suffer the slightest innovation. Those "masters" of Chinese medicine were contemporaries of Machaon and of Podalirius, who attended to the wounds of the besiegers of Troy.

No Chinese medical practitioner has ever dissected any portion of the human body. Accordingly, their ideas of anatomy and physiology are matters of faith—confirmed by images which have been reproduced during untold centuries. Their osteology teaches that the skull is formed by *one* bone; so is the pelvis; the number of ribs varies with the individual; and at the junction of the arm with the fore-arm is placed a cubital patella. According to Chinese splanchnology, the small intestine communicates with the cavity of the heart; while the colon, after describing sixteen circumvolutions, terminates by opening into the lung. The heart governs the vital processes, in combination with the cavity of the stomach; it supplies all ideas and all pleasurable sensations. The liver is the habitat of the soul, and it is from this gland that all noble and generous sentiments emanate. The gall-bladder is the receptacle of courage; its ascent in the body is the cause of a fit of anger. They have an idea of the continuous motion of the blood; but it seems to be the product of an imagination more riotously oriental than even that which created the other items of their physiological knowledge. They do not know the pulmonary circulation; they, naturally, know nothing of the valves in the veins; they do not even appear to have quite grasped the motor function of the heart itself; but they nevertheless profess to differentiate no less than *seventy-four* varieties of *pulse*—recognisable at the same time on the person of the same subject!

In its ultimate structure the body is composed of five elements: fire, water, metal, wood, and earth. Each of these elements is *in harmony* with the respective members of the series of *five* planets, *five* tastes, *five* colours, *five* metals, *five* solid viscera. All diseases originate from disturbances of the original and essential quintic harmonies of these elements.

As Dr. Matignon remarks, it is very fortunate that the Chinese have "la plus souveraine horreur pour la chirurgie." Direful would be the almost necessary results of the exploration of any of the cavities of the human body by the Chinese surgical practitioner! Accordingly, the "capital" operations are practically unknown; the procedures approaching the dignity of "operation" may be said to be limited to the opening of superficial abscess, the use of acupuncture, and the application of cautery. The Chinese horror of the application of the bistoury is not at all due to the fear of pain, of which these people are peculiarly, even strangely, tolerant. From the days of Confucius to the present, the Chinaman believes that the most precious gift of his ancestors is his body, and that every injury or loss of substance which this suffers is an insult to filial piety—the most devout of all his cherished feelings. This sacred feeling is specially characteristic of the Chinese religious philosophy, and permeates all classes of society. The patients who came under Dr. Matignon's care at the French Hospital in Pekin were induced to undergo necessary operations only on being assured that the ablated matters—tumours, injured or diseased limbs, &c.—would all be carefully restored to them on leaving the institution. With the same religious care the Chinese eunuch preserves (in spirit) the sexual organs of which he has been artifically deprived, that they may be buried with him at last; so that he may present himself with a whole body in the other world to the greetings of his adored ancestors. In this latter case there is a further reason, as we shall see.

The Chinese surgeon is, however, very liberal in the application of acupuncture: the procedure involves, of course, no appreciable loss of tissue. In his paper on the subject of the instruments of surgery used by the Chinese, which was published in the *Archives Cliniques de Bordeaux* (November, 1897), Dr. Matignon reproduces a native woodcut which indicates the position of the "elect" points of acupuncture, which are numerous and by no means far between. He also gives illustrations of the native surgical instruments which he had been able to pick up; they are small in number, and—individually—small in size, as might be expected. The Chinese chiropodist—"homme d'une habileté rare—a un arsenal beaucoup mieux fourni que le chirurgien." There are a small number of small bistouries and of acupuncture needles; we are told of a tongue-depressor, an *ouvre-bouche*, and an insufflation tube for the application of powders—especially in cases of diphtheria. The scissors and forceps call for no comment, except perhaps the *pinces a dents*, which make one think how much more formidable an enemy a Chinese toothache is than a British one. There is a *sonde cannelée* of the dimensions of a strong needle, with an incomplete ring at one end; this is pressed on an abscess till the skin projects through the ring, and the elevated portion is then incised with a bistoury. But *acupuncture* appears to be *the* great surgical procedure of the Celestials. It is employed in the treatment of fracture and of constipation, of ophthalmia and of cholera. Formerly there stood in the Collège Impériale de Médicine a bronze mannikin furnished with a number of small holes corresponding to the favoured points of puncture in the living body. At his surgical examination, the candidate was placed before this mannikin, which had previously been covered with paper; and he was required to pass his needle through the paper into the holes prescribed for the treatment of any disease which the examiner chose to name. Accurate aim proved trustworthy knowledge.

The *moxa* is essentially a Chinese (or Mongolian) surgical device. Dr. Matignon tells us that the llamas construct a moxa of wool, with peas and leaves of mugwort and centaury, dried, pulverised, and rubbed into its interstices. They treat cholera by a generally diffused acupuncture, with special attention to the sublingual, subungual, and circumanal areas. In the last resort, a modified moxa application is used to the epigastrium. A small pile of salt is placed thereon; over that a thin layer of ginger, then dried mugwort leaf. The whole is moistened with alcohol and ignited.

The uterine speculum, the midwifery forceps, and the urethral catheter are unknown to Chinese surgery. There are, however, small leaden bougies which are used to counteract the tendency to urethral atresia in the members of the semi-martyred army of *eunuchs*. This numerous and representative section of the Celestial community owes its existence to a special Imperial privilege, accorded only to the Emperor and to some members of his family. The Chinese Emperor possesses—nominally, at least—3,000 eunuchs. The Princes and Imperial Princesses have a right to thirty each; the nephews and young children of his Imperial Majesty to twenty; the cousins to ten. The representative descendants of the eight Manchu Princes who aided in the original foundation of the present dynasty are also privileged to possess ten eunuchs each. The privileges of the position are so well assured, and the struggle for existence in this over-populated nation is so great, that boys are sold by their parents, and young married men offer their own persons, for the operation of emasculation. No anæsthetic is used. The patient is bound on "une sorte de lit de camp," and his shoulders are firmly held by an assistant, while his legs are held apart by two others. The operator grasps the penis and scrotum at the root in the left hand, compresses and twists them, getting rid of as much of the blood as possible. When ready, he finally asks the question—of the parents in case of a young boy—"Do you consent?" If the answer be affirmative, he removes, with one rapid sweep of the knife, the penis and scrotum—with contents, of course, of the latter—as close to the pubo-perineal surface as possible. The knife may be straight or sickle-shaped; a small hatchet is sometimes employed. Figures of all three such instruments are given by Dr. Matignon, from a Chinese engraving. Startlingly crude as the operation is, there are not more than 3 or 4 per cent. of fatal cases. A tendency to cicatrical atresia of the urethral orifice sometimes proves very troublesome, especially in the younger subjects. But the most frequent troublesome sequela is incontinence of urine. This is tolerated for some time by the operator; if it persists, the latter beats his patient whenever the accident occurs. This treatment is said to be the only efficacious one, and is, accordingly, retained in high favour. A wooden or metallic bougie is used to prevent cicatricial contraction of the urethra proceeding too far. The ablated organs are preserved with religious care, and buried with the owner: the special necessity for this custom will be recognised when it is known that the Chinese Pluto transforms into mule all eunuchs who are transmitted to his realms without those relics. The external wound, after cicatrisation has been completed, presents an approximately triangular outline, with the apex below. The eunuch very frequently suffers from a combination of cicatricial stricture of the urethra with partial incontinence of urine. On this account he is often the victim of chronic vesical catarrh, and even of vesical calculus. Accordingly, with the partial incontinence of ammoniacal urine, the resulting odour is so well known that it is a popular saying in Pekin: "Il pue comme un eunuque; on le sent à cinq cents pas." Such are the usual surgical results of the most formidable operation known in China—as unsurgically performed by the privileged amateur. The omasculated individual—so rendered by the mere removal of the testicles—is not in request in the Celestial metropolis. The privileges of the female sex are very much restrained indeed among the mysterious Celestials. Accordingly, the Chinese of the twentieth century cannot raise the value of this article of classical luxury to the lofty level to which it attained by the competition of the luxurious Roman dames of the time of Juvenal. But the Chinese type of eunuch still ministers to the unspeakable depravity of his master, as did the similar specimen to that of his purchaser on the banks of the Tiber; when the *spado* and the *castratus* were both so familiarly known, and respectively appreciated by the different sexes at so high a pecuniary value.

Dr. Matignon points out that, curiously enough, the Mongolian system of medicine anticipated the late Professor Brown-Sequard by many ages in prescribing the ingestion of the testicles of rams to old men of evanescing energies. The use of mercury in syphilis is well known in those countries, but they are afraid to use it internally: it is accordingly applied to the skin.

If this communication prove of any interest to readers of THE MEDICAL PRESS AND CIRCULAR, I may at an early date discuss some of the internal therapeutics of the Chinese, and indicate their similarity to those of other primitive peoples.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 2nd, 1902.

INFANTILE TABES.

KAUFMANN at the "Gesellschaft der Innere Medizine" showed a boy, æt. 10; had always been healthy with the exception of measles when five years old. Three years ago incontinentia urinæ in the form of enuresis nocturna commenced and still exists. One year ago the gastric crisis commenced, which has assumed the form of pain, vomiting, and even fits every three or four weeks, lasting two or three days at a time. After forty-eight or seventy-two hours the attack gradually recedes, and is succeeded with a day's very severe thirst. During the interval, the boy is fairly well with a good appetite, and can eat anything without the slightest discomfort.

At the present time there is pupillary spasm, loss of patellar reflex, undoubted Rombergism and incontentia urinæ; beyond this there is no other loss of either motion or sensibility.

The papilla of fundus in left eye was pale, without any further very marked pathological changes. The deep and cutaneous sensibility of the extremities were intact. There was a decided thickening of both radial arteries, as well as deeper outline of the stomach on percussion. No symptom of acquired syphilis could be discovered. The mother had two other healthy children, and never had had an abortion; the father was not examined.

The whole symptoms, though complex, have an appearance of genuine tabes dorsalis occurring in a boy, æt. 7, who had always been well till this incontinentia urinæ commenced last year.

Against the assumption of it being paralysis is the perfectly normal and healthy condition of the mind; his intelligence is good, as the testimony of his teacher is that he is as well forward and mentally active as any other of his boys in the school.

Pseudo-tabes may equally be dismissed from our diagnosis, as Kalischer tells us that children suffering from this are more or less nervous, having symptoms of lues with psychic phenomena, transient forms of cramp, paralysis, epileptoid attacks, &c., &c.

Hochwart asked if the incontinence was only by night and never by day.

Kaufmann replied that it was invariably by night and never by day.

Hochwart thought the case of extraordinary interest, as enuresis nocturna existing three years was a very unusual early symptom in the course of infantile tabes dorsalis. Such a symptom must be of immense importance in the future differential diagnosis of infantile enureses

Neusser quoted a similar experience in one of his own cases of tabes dorsalis where the history of lues was indisputable.

NEPHROLITHIASIS INFANTUM.

Kienböck treated the Society to a demonstration in radiograms of concretions in the kidney with a discussion on the technique.

One of these cases of nephrolithiasis was interesting from history and long standing.

The patient was a female, æt. 32, who had been affected in youth. The bones were ankylosed, with an early inhibition of growth and hypoplasia of the whole system, except the cranial skeleton. There were also muscular atrophy and myxœdemal conditions of the subcutaneous cellular tissue associated with a pronounced infantilism.

The whole details of the skeleton pointed to an enchondral and periosteal dysplasia, with diminution of the facial bones—particularly the lower jaw—kyphoskoliosis, osseous ankylosis of the extremities, such as shoulders, hands, hips, knees, ankles, toes and fingers, with renal stones in both kidneys.

The disease seems to have commenced with a severe acute fever in the seventh year; the patient up till this age had been perfectly healthy. This was associated with pain, recurrent swelling of the joints and contractions; the latter occurring in the lower extremities three years after the first attack. The pain in the joints and diaphyses lasted for several years, but are now less painful. At the points of the fingers absorption has taken place in porous parts of the phalanges, leaving the fingers loose and wobbling. Renal colic is now almost gone, and has been trifling or stationary for sixteen years.

Kienböck did not consider this as a case of rachitis, as it usually passes as a temporary affection when appearing in youth. Neither could he entertain the idea of osteomalacia, as no bending or twisting of the bones were present, such as the heart-shaped pelvis, which usually takes place when feebleness sets in. Again, the acceptance of a lesion to the hæmatopoietic glands was a remote deduction, although the probability of infantile myxœdema might be pressed with reason.

His own opinion is that the cause was originally infectious, toxic or diathetic, which injured the entire system, especially the joints, producing in the first place synovial polyarthritis of an acute nature at first, subsequently recurring, and finally closing with contractions, ankylosis, and loss of power in the phalanges. The cessation of the growth of the long bones, spongiosa and muscular atrophy of the skin, must all be viewed as arthogenic in origin. The atrophy of the facial bones may have been inflammatory, as there is very little impairment of the mobility. The broken teeth and altered condition of the bones are in favour of this assumption.

Neusser asked what value should be put on the absence of the large glands in this case, as he was inclined to attribute the whole cause of the retarded growth to a loss or lesion of the thyroid gland.

Kienböck replied to this by saying that the neck was so short and deformed that he could not practically palpate this organ with any other result than a negative one, on which he put no value as thyroid psychical changes were absent; and, what was more important in the history of the case is that individuals suffering from infantile myxœdema do not reach thirty years of age! Again, the patient was born in Vienna, and for seven years enjoyed excellent health in a city where endemic cretinism is unknown. It must be admitted, however, that there is a combination of hæmatic gland disease in combination with the polyarthritis as the affection of the hypophysis shows. It is assumed that the general or "consecutive" trophic disturbance so injured the glands and secretion that growth was checked.

Atasia et Abasia with Nystagmus.

Hofbauer showed a patient who had suffered from astasia et abasia, or inability to stand or walk after emptying a large quantity of chloroform from one vessel to another in the laboratory. This form of chloroform poisoning is rather unique. After finishing he was suddenly affected with severe headache, vertigo and a pungent, sweet taste in the mouth. Next morning he felt fairly well, but in the afternoon was unable to stand or walk. When admitted into hospital the motility and deep sensibility was intact, although Romberg's phenomenon and nystagmus were very prominent. Ocular examination revealed no morbid condition in the fundus or nerve apparatus. After three days rest walking was again tried, which gradually improved till both abasia and atasia as well as the nystagmus had quite disappeared.

The Operating Theatres.

GUY'S HOSPITAL.

Pott's Fracture.—Mr. **Arbuhnot Lane** operated on a woman, æt. 60, who had sustained a bad Pott's fracture a year before. She had been unable to walk, or indeed to bear her weight upon the damaged foot, and preferred to have it amputated if the pain she suffered from it could not be alleviated. It was evident that the internal malleolus had been broken off, that the lower end of the tibia had been displaced forward, and that the fragments of the fibula formed with one another a considerable angle. She had been treated by very competent surgeons, who, Mr. Lane said, adopted the usual ineffective methods of treatment, and were satisfied to leave the poor woman a helpless cripple for the rest of her life rather than obtain for her a perfect mechanical result by forgetting for a few moments their obsolete and pernicious creed. Mr. Lane made an attempt to replace the tibia and fibula in their normal relationship to the astragalus, but the length of the interval that had elapsed since the injury, the degree of displacement of the fragments, and the age of the patient rendered it impossible. He was obliged to excise the ankle-joint, which he did by means of a chisel. The progress made by the patient was most satisfactory in spite of her age and the considerable extent of the operation.

Mr. Arbuthnot Lane operated in a case of fracture of the ulna at the junction of the middle and lower thirds. The fragments were much displaced on one another, and there was approximately little or no callus connecting their ends. The displacement prevented any rotation of the radius in its length, and the want of firmness of the uniting medium rendered the fore-arm hopelessly insecure and useless. More than three months had elapsed since the receipt of the injury, and the man was unable to do any work whatever. The fracture had been treated, Mr. Lane said, by that pernicious arrangement which is called an internal angular splint. The ends of the fragments were exposed and freed from the callus and fibrous tissue about them. They were fitted accurately together and fixed immovably in position by a couple of pins of silver wire. The progress made by the case was most satisfactory, and the bones united firmly and securely with no displacement whatever. Mr. Lane pointed out the very great difficulties that are often experienced in operations performed to restore to their normal form badly united fractures of the radius and ulna, which are exceedingly common. He had operated on a large number of these cases, affording the patients a greater or less amelioration of their mechanical disability. He had called attention to the folly of treating fractures of the radius and ulna by the internal angular splint, and had given his reasons against it in a recent number of the *Clinical Journal.* He hoped that a growing familiarity with radiography would educate the public into appreciating the extraordinary weakness of the splint treatment of fractures, and the facility, safety and certainty of operative interference in suitable cases. A steady improvement in the aseptic methods of the surgeon will also render him more confident in himself and more ready to adopt a scientific treatment of those injuries.

CANCER HOSPITAL.

Laparotomy *per se* for Incurable Abdominal Cancer.—Mr. **Chas. Ryall** operated on a woman, æt. 58, who had been admitted suffering from abdominal pain and tumour. She had had these symptoms for the last three months, during which time she had lost both flesh and strength. There had been occasional vomiting and obstinate constipation had been a marked feature. The pain was referred to the right hypochondriac region, and extended round to the back; there had never been any attacks of jaundice. On examination the cæcum and ascending colon were found to be much distended; the tumour could be detected in the right hypochondrium; it was round and smooth in outline, with a fair amount of mobility, and appeared to be connected with the liver. Malignant disease was diagnosed and laparotomy was recommended because, if even the tumour could not be removed, yet the patient would probably derive considerable benefit from the simple laparotomy. The abdomen was opened in the right linea semilunaris, and a malignant growth was found springing from the under surface of the liver. The hepatic flexure of the colon was attached to it by some firm bands of adhesions which, no doubt, were the chief cause of the constipation and distension of the cæcum and ascending colon; they were therefore divided. It was found quite impossible to attempt to eradicate the growth, so the abdominal wound was closed and the patient put back to bed. Mr. Ryall said that he considered all cases of intra-abdominal malignant growths should be explored, even where it was quite apparent that any radical operation was out of the question, as in his experience so many of these cases derive considerable benefit from the result of the laparotomy alone, pain being relieved, the growth shrinking, the subsequent history of the case being chronic, the patient improving to a marked extent, and life being prolonged sometimes for years. It is difficult, he thought, to explain the therapeutic effect of this simple laparotomy, and why it should frequently retard the progress of malignant disease in one case and in another cure a case of tuberculous peritonitis. Possibly in both cases it might, he considered, be due to some vascular change resulting from stimulation of the splanchnic nerves. In his experience, he remarked, he had had one very remarkable case of an abdominal tumour in a man, æt. about 45, who was suffering from persistent and progressive jaundice, rapid emaciation (the weight falling from fourteen to ten stone). There was constant vomiting, the patient being unable to retain any solid food and but small quantities of liquid; he had suffered from these symptoms for six months. For these symptoms various drugs had been tried, but the patient progressively became worse. On abdominal exploration a nodular growth, the size of a clenched fist, was found implicating the head of the pancreas, and as radical operation was impossible, the abdomen was closed and the patient put back to bed. At the time of operation a hope was anticipated that some benefit might be derived from the simple exploration, but scarcely to the extent which subsequently took place. Without any other treatment than rest in bed for a few weeks this patient began and continued to improve in a marvellous manner; the sickness ceased, the jaundice gradually disappeared, the tumour in a similar manner disappeared. The man rapidly put on flesh and now, nine months after the operation, he weighs, and has for some months weighed, over fourteen stone; he feels well and strong, is doing his ordinary work, and is to all intents a healthy man, without any apparent evidence of disease.

Cancer Research.

The Treasurers of the Middlesex Hospital have received from an anonymous donor, per Mr. A. Pearce Gould, F.R.C.S., the sum of £100 to the fund for developing the work of the Cancer Research Department of that hospital. Messrs. N. M. Rothschild and Sons have given £1,000, and the Leathersellers' Company £250, towards the £100,000 required for cancer research.

WEDNESDAY, AUGUST 6, 1902.

THE ADDRESS IN MEDICINE AT THE BRITISH MEDICAL ASSOCIATION MEETING.

To Sir Thomas Barlow has fallen the task of delivering the Address in Medicine at the Manchester meeting of the British Medical Association. His oration, dignified and scholarly, was worthy of the long line of distinguished addresses that have fallen from his predecessors. He began with a graceful reference to the late Sir William Roberts, who addressed the Association under similar circumstances a quarter of a century ago in Manchester, and who has left an indelible mark in the pages of modern medicine. Sir Thomas Barlow touched upon a great many subjects in the course of his address, but, as he pointed out, it would have been impossible even to enumerate all the advances made by medicine during the twenty-five years that had elapsed since the last meeting of the Association in that hospitable city. The main thesis of the address was that the advances in the treatment of disease have been real and satisfactory in proportion as they have been harmonious with the complete knowledge of the natural history of disease. In other words, our curative methods have become more extended and satisfactory as our knowledge has come to rest upon a more assured basis of facts. In some cases the discovery of the exact cause of a malady has not been attended with a corresponding ability to counteract its ill-effects. An example of that kind is found in the case of tetanus, which in its acute form is not yet amenable to the tetanus antitoxin, although some benefit is obtainable from its administration in chronic forms of that formidable affection. It is impossible to doubt, however, that sooner or later the key to the cure of that and other maladies of specific origin will be safely grasped in the hand of science. In the present stage of human knowledge much remains to be learned, and much of our therapeutic practice necessarily rests upon an empiric foundation. As every thinking physician must recognise at an early period of his career, it is in the period of half knowledge that the practice of medicine has often cut a sorry figure, for theoretical lines of treatment, based on incomplete physiological and chemical data, have often produced melancholy failures. From the reverse of that picture Sir Thomas Barlow draws a reassuring lesson. The outcome of the new experimental pathology of the last quarter of a century, he points out, controlled by clinical observation, applied and tested by clinical experience, has justified us in claiming that at length our work has ceased to be fairly described as groping in the dark, and that in some definite instances medicine has justified for itself the designation of an exact science. Even in dealing with incomplete data methods have gone on improving as the result of careful study and investigation. Although we are still ignorant of the micro-organism of rabies we are none the less convinced that it is the cause of the disease. The working hypothesis of Pasteur that in the dried spinal cord of an animal that has died of rabies the micro-organisms are destroyed, but that the immunising substances remain active, seems to have been more than justified by subsequent experience. There can be no reasonable doubt as to the prophylactic value of Pasteur's methods, although no beneficial effects follow their employment in the developed disease. But when a complete analysis of the life-history of the organism has been attained we may fairly look for still greater results in the therapeutics of the malady. The lecturer drew a striking instance of a kindred nature from "the great triumph of English protective medicine, namely, vaccination." One of the most valuable results of the recent Royal Commission on Vaccination was that it gave a direct negative to those who thought that finality had been attained on the old lines. The most recent methods of preparation by carefully-regulated glycerination, and the getting rid thereby of a large amount of the secondary infection, marks an enormous advance in the practical application of vaccination. The variable results of antistreptococcic serum point to the fact that although the streptococcus is the organism common to many forms of septicæmia, it seems there must be various strains, each requiring its special antitoxin. Other parts of this brilliant Address dwelt upon the treatment of various specific conditions in the light of modern science, notably diphtheria, tuberculosis, and malaria. Not the least suggestive portion of the speaker's remarks dealt briefly with the possible ways in which future advances would be made. The Manchester Address in Medicine will be remembered for its breadth of grasp of the practical issues before the profession, and should be carefully read and re-read by everyone interested in a great and progressive subject, dealt with, as it was, by a master hand.

THE REVISED CURRICULUM OF THE IRISH CONJOINT EXAMINATIONS.

THE alterations in the curriculum of the Conjoint Examinations by the Royal Colleges of Physicians and Surgeons in Ireland, recommended by a special Conference Committee appointed for that purpose, have been finally adopted by both colleges, and have been brought into force. The changes, which have been made, have been the result of an effort to bring the examinations of the colleges into more close correspondence with the examinations of the English and Scottish colleges. Perhaps the most important of them is the acceptance of the principle that the subjects of the first professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the colleges, after due inspection, for instruction in these subjects. The principal remaining alterations are the elimination of one course of instruction in Anatomical Demonstrations and Dissections and of the course of Practical Pharmacy, the alteration of the period of instruction in mental diseases from three months to one month, and the addition of a systematic course in Pathology. Further, various slight alterations have been made in the grouping of the subjects for the different examinations, with the object of simplifying the curriculum as much as possible without interfering with its value. It will doubtless be a subject of regret to many that the Royal colleges should have found themselves compelled to omit any portion of their former curriculum, and especially that they have been drawn into copying the by no means commendable example of the English colleges regarding the first year of medical study. Unfortunately, however, the Irish colleges do not appear to have had any alternative. If the General Medical Council was powerless to prevent the deviation of the English colleges from its regulations, the Irish Colleges were similarly powerless to prevent the deviation of students to England, save by offering them as simple a curriculum as the other licensing bodies. A certain amount of misconception appears to have been present in the minds of some members of the profession as to the object of the alterations which have been adopted, and an attempt was made to show that in reality it was a rearrangement of hospital fees which should have occupied the attention of the Conference Committee and not a curtailment of the curriculum. This, however, is scarcely correct. It is a matter for deep regret if the alterations in the regulations regarding the first year of medical study prejudicially affect the medical schools, but that some reduction, either real or apparent, in the number of years of medical study was necessary, and that without such reduction the lessening of fees for hospital attendance would have been of no avail, is apparent to all familiar with the matter. Similarly, other alterations were made to enable the same certificates of lectures taken and courses attended, which would admit a student to any of the professional examinations of the English and Scottish colleges, and even to those of the Royal University of Ireland, to also admit him to the corresponding examination of the Irish colleges without necessitating attendances on additional courses with a corresponding delay in time. The time of the student is quite as valuable as his money. We regret that it should have been found necessary to make some of the alterations which have been made, a regret which we are sure is felt by those who recommended them; but the alternative to making them was to see our Irish students passing over into the hands of the English and Scottish licensing bodies. It was not the Irish colleges who voluntarily adopted a course of curriculum pruning.

THE STORING OF POISONS.

One of the strangest anomalies in our social state is the care we take in the sale of poisons. The pharmaceutical chemist, if not actually required to keep poisons locked up, is expected to do so, and as a matter of fact all the more quickly lethal drugs are stored under lock and key. In the sale a series of precautions is enforced, rightly enough, to make sure the purchaser recognises the dangerous nature of the commodity he buys, and also to test, to a certain extent, his suitableness to use the poison. So far the law takes almost parental care. But once the retail customer puts the drug in his pocket the law enforces no obligation on him, He may allow the poison to lie on the nursery floor or the kitchen table; he may put it on the mantelpiece or in a cupboard. From this carelessness many deaths have resulted, and the wonder is that these have not occurred more frequently. We are reminded of this by the report of a case in the newspapers last week, in which a woman was accused before the magistrates of having attempted to poison her husband by giving him a tumbler of water in which lumps of cyanide of potassium were partially dissolved. Our readers are aware that cyanide of potassium is one of the quickest and most deadly of poisons, and in this household we find it in such quantities and so kept that a woman finds large lumps of it. In a case tried not so many years since, sworn evidence was given that ounce papers of powdered strychnine lay on shelves in the kitchen, the papers torn open. We think it is time that all persons buying poisons, for trade or other legitimate purposes, should be required to keep them in a bottle or jar locked up, except when in actual use. If when a purchaser of a poison brings it home he can let it lie about, careless of the consequences, all the previous safeguards are seriously discounted. In a private house even more than in a pharmaceutical chemist's the utmost care should be taken in the storing of poisons. No person should be allowed to keep them in a place where children or servants could come at them. And we would go further and prohibit the sale of poison to any person of drunken habits. It might lessen the risk if the purchaser were required to sign an obligation binding him to keep the poison locked up, in a place separate and distinct from all powders, bottles and so forth, required for household purposes. All tradesmen and others using arsenic and the cyanides should be compelled, under the penalty of a smart fine, to keep their chemicals in a place of safety and to see that they are all locked up before discontinuing business every day. These precautions may be considered very stringent, but no stringency can be complained of that is necessary for the preservation of life.

Notes on Current Topics.

The Health of the King.

It is with profound satisfaction we learn that the progress of the King towards recovery is presenting an unbroken record. No apprehension need any longer be felt that his Majesty will be unable to attend the Coronation ceremony on the 9th instant, and to withstand the fatigues of that important day. At the same time it must be remembered that no convalescence from so serious an operation as that recently undergone by his Majesty can be looked upon as absolutely safe and free from the risk of complications. In the present case we are glad to say that there is not the slightest reason to suggest that any untoward accident may intervene in the course of the few days that remain between now and Coronation Day. His Majesty has had the best modern surgical skill available, which in itself is nine-tenths of the battle. His own cheerful and resolute character, we doubt not, has contributed in no small degree to the happy issue that has filled the whole heart of the nation with heartfelt satisfaction. It now remains for the medical men in attendance to take every precaution that no unnecessary risk is run during the journey back to London and the subsequent ceremony. It may be taken for granted, however, that his Majesty's medical advisers will continue to exercise their skilful care and ministrations in whatever direction their experienced foresight may determine.

Small-pox in London.

The downward curve marking the course of the small-pox outbreak in London has maintained its fall in a satisfactory fashion. During the past week there were some 400 patients under treatment, but on the 24th inst. the Asylums Board received no notification of a fresh case, a freedom which has not been similarly recorded for eleven months. The outbreak commenced in earnest in August, 1901, in which month 96 cases were reported. There were 188 cases in September, 309 in October, 473 in November, 804 in December, 1,283 in January, 1902, 1,572 in February, 1,999 in March, and 1,370 in April. In June the number of cases dropped to 602, and in the present month thus far there have been only 148. The total deaths from small-pox from August 10th, 1901, to July 24th, 1902, have been

1,620. That figure is equivalent to about 17 per cent. of the admissions to hospital, which were about 9,000. The cost to the public has been very heavy, and has been estimated to be between £400,000 and £500,000. In 1877 there were 6,620 cases; in 1881, 8,671; in 1884, 6,567; and in 1885, 6,344. If the present fall in incidence of the disease, therefore, is a mark of its early disappearance, London will have escaped pretty lightly. It is to be feared, however, that the present fall points merely to a lull in the storm. It is highly satisfactory to learn that not a single nurse has even been attacked by the malady.

What are Women Sanitary Inspectors?

The proper title of the women who have been appointed to the post of sanitary inspector in various parts of the United Kingdom is exercising the minds of some of the local authorities. It has been attempted to solve the problem in various ways. As it is clear that these women officers do not overlook sanitary matters the term "sanitary inspector" applied to them is evidently a misnomer. Some worthy councillors, who apparently scent reproach in the good old Saxon word "woman," have substituted "female" or "lady." The average sensible-minded Englishwoman, whatever her station, would most likely choose the term "woman" as the best and most suitable description. Aristocratic Kensington thinks otherwise, and has called these officials "lady inspectors of workshops." Apart from the snobbishness of the word "lady" in this connection, the rest of the innovation seems sensible enough. If the women are appointed to inspect workshops it is better to imply that duty in their titles rather than to call them by names that furnish an entirely misleading idea of their duties. In some districts their chief duty is to inspect small tenements and lodgings, and to advise the poor in elementary matters of health. The chief danger of calling such women "sanitary inspectors," so far as appears on the surface, is, that being appointed in place of the ordinary staff of men sanitary inspectors, but discharging other duties, they may indirectly tend to lessen the working sanitary staff, which is already almost universally far too small.

The Evolutionary Aspects of Infectious Diseases.

On two separate occasions in the course of the present year Professor G. Frank Lydston, of Chicago, lectured, "by invitation," on the fertile subject of "The Evolutionary Aspect of Infectious Diseases, with especial reference to the local Venereal Diseases." The published reports form one of the most suggestive documents which we remember having read for some years—in connection with any department of the healing art. His grouping of, and reasoning on, such facts as: dogs succumb to the anthrax bacillus only when pure cultures are injected intravenously; young rats die of general infection, while older ones develop only small abscesses, unless a large number of bacilli are injected directly into the circulation; frogs and tree toads are resistant at medium, and susceptible at higher temperatures; fowls resist anthrax ordinarily, but if they become chilled they rapidly succumb to it; pigeons resist it, save when semi-starved; the tetanus germ is inoperative save when inoculated simultaneously with foreign material, such as splinters of wood, dirt, and pus;—are most suggestive. "How familiar the foregoing facts sound to the student of a quarter of a century ago. Age, exposure, innutrition, lowered resistancy—special conditions as invitations to contagion. Really, specific science has not yet done away with old-fashioned things. The pneumococcus is the specific microbe of pneumonia, but for some reason it often demands a chilling of the cutaneous surface in order to flourish and wax fat in the lungs." And the lecturer goes on to reflect: "How unfortunate that we cannot duplicate in the laboratory the conditions natural to the germ. How much more modest should be the claims of modern bacteriology." The successful employment of injections of pure cultures of Bacterium coli commune in chronic constipation is a highly suggestive result. The Bacillus anthracis has been converted by evolutionary culture into a harmless putrefactive organism. Pasteur had modified nearly all disease germs by culture, and established a great biological law; but the profession at large never grasped the meaning of his results. He merely gave feeble imitations of nature's work under conditions which man has not yet been able to reproduce. Dr. Lydston expresses full belief in the *de novo* origin of venereal disease. Possibly the twentieth century will rewrite the pathology of infective diseases. That which has been built upon bacteria would appear to require to have its foundations readjusted.

Infection and Tissue-Resistance.

The subject of "Lung Development in the Child" is dealt with in the May number of the *Journal of the American Medical Association* by Dr. J. Allen Gilbert (Portland, Ore.). Besides pointing out the importance of good food, fresh air, judicious gymnastic exercise, &c., Dr. Gilbert contributes observations on the importance of prophylaxis and the maintenance of tissue-resistance, which contain a far greater percentage of sound sense than we usually find in the majority of scientific contributions to practical medicine. As he truly states, the individual patient is now often forgotten in the eager pursuit of the respective causative germs. "There are two elements to be considered in ætiology and prophylaxis: the external agencies and the individual himself. It is difficult to decide which is the more important. Pathological conditions always depend upon the relative strength of the infection and the infected. Were it not for the vital resistance of the human tissues against external invasion, our history would have been written long ago. Prophylaxis for all infectious diseases can be summed up in the one principle of weakening the invader and strengthening the invaded. Relatively too much strength is expended in weakening and destroying the invader, leaving the individual fearful and defenceless in the presence of his self-induced weakness." The limitations of that very unreliable quantity, the human understanding, seem to have effectually shut out from the mental view of the average bacteriological pathologist the most important fact that, in any given case of infective disease, the successful catching and killing of all microbes present would not effectually cure the patient; also the great preliminary fact that no microbe can ever take root in tissues which have not already been placed in the appropriate condition of receptivity. All disease germs which fall upon perfectly healthy tissues necessarily undergo the fate of that portion of the seed of the gospel parable which "fell upon a rock."

Trichina Spiralis in Australasia.

In a recent number of the *Australasian Medical Gazette*, the first recorded case of *trichina spiralis* hailing from the Antipodal Continent has been published by Dr. E. Angus Johnson, of Adelaide. A painter, aged 44, who had never been out of the Colony, developed cancer of the lower jaw on the right side, for which he submitted to an operation. He also presented evidence of aortic and mitral valve disease. There was a record of *typhoid fever* of four years' previous date. The "notes" of that *typhoid* attack were as follows:—"When seen by the doctor for the first time he had been ill for three weeks with dull heavy pains in the forehead, back of head, chest, thighs, right side; and general debility; also a slight cough. He had been in bed one week before he saw the doctor, and remained two weeks more in bed, by which time the pains had entirely disappeared. His temperature was 100·4° in the morning and 102° in the evening that he first came under medical notice, and then was normal for the rest of the illness." The cancerous lower jaw of this patient was removed by Dr. Johnson and Professor Watson, of Adelaide. It was observed "whilst cleaning out the glands in the neck" that the muscles (sterno-mastoid, sterno-hyoid, and digastric) were "studded with small white specks resembling the ova of pediculus capitis. These deposits were noticed to be much more numerous towards the tendinous ends of the muscles than in the muscles themselves." Dr. Johnson's patient had been a great eater of polonies (sausages), and had suffered from symptoms of plumbism three or four times since his "typhoid." He appears to have recovered from the operation, and we are promised a later report. The conclusion for the present is, "Now that it has been discovered here, a further crusade against rats must be commenced, since the trichina spiralis is a parasite belonging to that rodent, and the pig gets infected from eating these diseased rats (which are frequently found infesting slaughter yards)." What with the consequences of the informations which have been filed against the rat in the plague and trichinosis cases, we anticipate that the future earthly career of "that rodent" is not likely to prove a happy one!

The Vision of the Army Recruit.

Some very sensible criticism on the present system of testing the vision of his Majesty's Army recruits is given in the last number of the *Indian Medical Gazette*. The test-dot card now in use is, of course, familiar to all. The dots are each one-fifth of an inch in diameter, and should be visible to a normal eye at a distance of fifty-seven feet, as it then subtends an angle of one minute. Some persons can count them even at a distance of ninety feet. The Army candidate is required to count the dots at a distance of ten feet only—represented a standing visual acuity of approximately one-sixth the healthy normal. For departments, &c., counting the dots at five feet is sufficient. The former (ten feet distance) test assures us that the soldier will be able to see a bull's-eye of three feet diameter at a distance of 600 yards—more or less distinctly. The object of the test professedly is to decide whether they are capable of becoming good marksmen. As Surgeon-Captain Munson, U.S.A., writes: "Successful use by the soldier of long range fire-arms demands that his vision *shall be normal* or so nearly normal that there need be no question of his ability to see the target at all ordinary ranges." From the remarks already made, it will be seen that there is no guarantee of such standard supplied by the test to which our recruits are subjected. And the comment of the "editorial" on this question in our contemporary is surely a just one:—"It is, to say the least, anomalous that such care should be taken in measuring height and chest to the fraction of an inch and remain satisfied with our present meagre knowledge of the visual capabilities of the recruit."

Insects and Civilisation.

An accomplished scientific writer, H. C. McCook, D.D., Sc.D., calls attention in the June number of *Harper's Magazine* to the important part which insects have throughout played, and still continue to play, in the adaptation of the earth's surface to the wants and comforts of man. Even before the publication of Charles Darwin's epoch-making volume on "Earthworms," this reverend author had contributed to the pages of the "Proceedings of the Academy of Natural Sciences of Philadelphia," a paper which revealed an agency of the ants of that city in their treatment of the upper layers of the soil, very similar to that which was so lucidly demonstrated for the efforts of the previously ignored earthworm by the great apostle of evolution in his last contribution to the study of his life. Indeed, it must now be recognised that insects dispose of decaying and mouldering vegetable and mineral matter by processes analogous to those by which the bacteria deal with diseased and dead animal matter; they tear it to pieces, they plough and harrow it, and spread it abroad in new and neutral forms ready for the reception of new seeds of life, and for future contribution to chosen representatives of the various kingdoms of nature. The reflection also necessarily recalls the importance of the presence of the flea in the transmission of plague, and of other insects in other inoculable diseases.

Identification of the Fundus Oculi.

IN a recent number of the *Journal of the American Medical Association* Mr. F. Weymann has advanced the theory that the individual human being can, at any time throughout the remainder of his or her life, be surely and incontrovertibly identified by examination of the *fundus oculi*, if accompanied by an approximately accurate drawing of the optic papilla and an investing retinal circle, whose circumference is separated from the scleral ring by a distance equal to the length of two papillary diameters. Even the disposition of the arteria centralis retinæ and its branches would alone, according to this observer, be sufficient to establish identity. So far unlimited is the multiplicity of the anatomical dispositions of the vascular ramifications, that he has never yet found the arrangements alike, even in the two fellow-organs of a single individual. The points to be specially noted for future identification are:—(1) The method of division, dichotomous or otherwise; (2) the exact point of division; (3) the exact angles of the vessels with the primary meridians; (4) the exact distance of one divisional point from the other; (5) the relative size of the divided twigs; (6) the angle of division; (7) the course of the twigs, straight, curved, &c.; (8) the exact distance, everywhere and at every point, between venous and arterial branches (parallelism, convergence or divergence, twining, &c.). If this very interesting communication receive satisfactory corroboration from other observers, the officers of justice can be furnished with another important weapon. A criminal cannot so successfully modify a *fundus oculi* by physical agents as he can his cutaneous surfaces—complexion, features, finger-tips, &c. The application of paints, cosmetics, caustics, new and bewildering tattoo decorations, and such, may be satisfactorily excluded. There is surely a great deal in this.

Surgery of the Prostate Gland.

THE surgery of the prostate gland has been well in evidence during the past five years. The latest important contribution is a very interesting one by Dr. W. N. Wishard, of Indianapolis, Indiana. The author deals with the procedure of direct application of the cautery to the affected organ, which he does through an artificial opening in the perineum. We are quite of his opinion that "the cautery when used upon the prostate should be used with the operative area under the direct observation of the operator," and that "changes in the condition of the urine, functional disorders of the bladder, and digital examination by the rectum afford very inadequate evidence of the character of the obstruction." For the application of the cautery, Dr. Wishart has devised a special instrument. He uses a straight tube of six and a half inches in length and forty-two millimetres in circumference, with an oblique opening at the distal end. There is an "auxiliary tube" which carries a small incandescent lamp of low heating power. He uses three modifications of the galvano-cautery knives—for the nose, throat, and corresponding localities. To obtain a wider range of exploration and of contact he has utilised the principle involved in the construction of the so-called "alligator-jawed" forceps. By this means the cautery-knife can be made of any length and shape, and can be readily used for the removal of intra-vesical tumours. When such operation is called for, the bladder is previously distended with air, and the lens system in the auxiliary tube is so arranged that the surgeon can "see at a right angle." The use of such an instrument is, of course, of immense value for diagnostic purposes alone. Dr. Wishart reports some very encouraging results, which we think that he has thoroughly deserved. His methods represent a worthy item in the progressive march of twentieth-century surgery.

A Case of Double Tongue.

A RECENT number of the *New York Medical Record* contains a description of a case of double tongue which was discovered in the buccal cavity of a Jewish boy, æt. 5, by Dr. Albert Setz, of McMinnville, Tennessee. This boy had suffered from pain in the mouth, due to carious teeth; and his father in exploring for the source of pain, in the night preceding the visit to Dr. Setz, found the duplicate organ springing from the angle of junction of the normal tongue with the floor of the mouth. It was about an inch in length, and somewhat broader than the normal tongue which lay above it. He is one of a family of six, and neither he nor any of his brothers appear to possess any other noticeable abnormality. However, the abnormal lingual organ does not appear to trouble the boy in any way, and he speaks with the greatest distinctness. Accordingly, Dr. Letz did not recommend any operative procedure, except for the treatment of the carious teeth.

Tenement Houses in Dublin.

THE fall of a tenement house in Moore Lane, in which a child twelve years old lost his life, is an object-lesson that cannot quickly be forgotten. At first the sympathy of the public for the parents of the boy who was buried in *débris* so occupies the people that the very serious nature of the fatality is almost lost sight of. Here is one of a large number of houses which are occupied from roof to cellar by the poor, usually one family to a room, and one of these houses becomes so rotten with age that it falls. Can it be said that such houses are suitable for dwellings, even for the poorest? Ought an owner to go on receiving rents for rooms which are little more than death-traps? How does it come to pass that with a large sanitary staff of highly-paid officers that unsafe buildings are not condemned and taken down instead of being allowed to fall down as this and many other such have done in the city. One death only in this catastrophe; but how many children would have been victims had the poor room-keeper been less intelligent or less active in clearing a large number out of the house? The poor are troubled about so many things, life with them is so hard, the perpetual struggle for existence so sharp, that fatalities such as the Moore Lane one are soon forgotten by all, except, perhaps the boy's parents; and the old houses with broken windows, creaking doors or hingeless ones, with their dirty walls and insanitary surroundings, remain the only refuge for the destitute.

Malpraxis Action against a Colliery Surgeon.

At Nottingham Assizes last week a colliery surgeon, Mr. W. C. Rainsbury, was defendant in an action brought against him by a collier for negligent and unskilful treatment. The plaintiff's elbow was badly crushed on November 26th, 1900. The arm was much swollen, and it was some time before Mr. Rainsbury could diagnose the injury. In the beginning of January the plaintiff went to two bone-setters. Dr. Rainsbury advised him to go to the Nottingham General Hospital, where, by means of the X-rays, it was discovered that there was dislocation of the elbow and other injuries. Eventually the plaintiff came to London, and was operated on at Charing Cross Hospital. The surgeon, Mr. Charles Gibbs, stated his opinion at the time that any practitioner of ordinary skill and with ordinary care could have reduced the dislocation by the ordinary process immediately after the accident, and that the swelling would not have been so great as to preclude the possibility of a definite diagnosis. This statement, if correctly reported, certainly does not agree with the average surgical experience. A London hospital surgeon is the last man in the world we should have expected to appear in the witness-box with dogmatic assertions of this kind reflecting upon the skill of brother practitioners. Hospital surgeons sometimes require sympathy, forbearance, and charity for errors of omission and of commission. *Crede experto.*

Overcrowding on a Troopship.

A cablegram from Albany, Western Australia, states that on the arrival of the troopship *Drayton Grange*, with 2,000 troops on board, complaints were made as to the want of accommodation which had been experienced during the voyage. The health of the ship was anything but satisfactory, considering there were 100 men under treatment, suffering from measles and pneumonia, of which nearly a half were severe cases. This is a serious state of affairs, and one which is absolutely unnecessary. There are plenty of passenger steamers plying between the Cape and Australia, and if, when the *Drayton Grange* had on board as many troops as could be carried with comfort, a hundred or a hundred and fifty remained over, which number, naturally, would not be large enough to warrant the sending of another transport, it would have been better to have given these men their passage on one of the regular passenger ships. This was done over and over again when sending troops to the front, and when, moreover, time was an important factor. It is surely unnecessary at this hour to enlarge on the bad effects of overcrowding, but bad as it is in all cases, it is worse in the case of men more or less worn out by a long and arduous campaign. Hurry is generally a mistake, but is doubly so when unnecessary. Men who have fought, and fought well, for their country deserve that every care should be taken of them. It is no economy to overcrowd a troopship, for the expenses incurred by the baneful results of such a process are sure to be, in the end, far above the expenditure necessitated by a proper and seemly arrangement. The transport organisation in connection with the war in South Africa has been the admiration of the civilised world, and it would indeed be a thousand pities if, for want of a little attention and forethought, such a brilliant achievement were marred at the eleventh hour.

Mummer Fever.

There is one thing with which the Indian Princes and the Colonial Premiers cannot fail to have been impressed with during their stay in England, and that is the exalted opinion entertained in official circles of our leading actors. As soon as the visitors had arrived, successively each actor-manager held his court, and the attendance of the nation's illustrious guests was most dutiful. This is all very pleasing, but we doubt if at any other period in the history of England, or anywhere else, even at the present day, a body of princes and statesmen visiting the country would have been expected to show such absorbing interest in stage personalities. This rush to the green-room may meet with the sagacious approval of young ladies in their teens, but brings a smile to the face of the average man of the world.

Nitrate of Silver in Ophthalmia Neonatorum.

Ophthalmic surgeons, as a rule, view with distrust the prophylactic treatment of ophthalmia neonatorum which was introduced by Crédé. Obstetricians, on the other hand, who have had practical experience of its value, consider it to be almost, if not entirely, trustworthy. It certainly has very greatly diminished the frequency of ophthalmia commencing during the puerperium, while it is more than likely that the cases of this disease which are seen in eye dispensaries in slightly older infants are due to a subsequent infection. Recent statistics which Runge has collected at Göttingen during the past five years show that one thousand new-born children were treated. Not one had an early infection of the eyes, and in only a single case was there a later infection, occurring at the beginning of the second week. Even in this case the infection ran a rapid and mild course—the inflammatory process disappeared in forty-eight hours. Including figures collected at Göttingen by Schallehn during a previous period, Runge is able to report 1,917 cases without a single early infection. On two separate occasions groups of pregnant women were examined at the Göttingen clinic for gonorrhœa. Of the first group, 25 per cent. were found to have infections; of the second group 20 per cent. were gonorrhœal; hence the opportunities for infection of the new-born were frequent enough. Runge regards the effectiveness of the Crédé procedure as unquestionable. A 2 per cent. silver nitrate solution does occasionally produce a mild conjunctivitis. A 1 per cent. solution has not this disadvantage, and is just as successful a disinfectant as the stronger solution.

Oil of Wormwood as an Abortefacient.

A recent inquest at Runcorn reminds us of the fact that oil of wormwood, or absinthe, in large doses does sometimes bring about abortion. The drug was obtained from a Liverpool chemist, who forwarded a quarter of an ounce of the drug in question to a certain village in answer to two separate orders received by letter. The drug was not scheduled as a poison, and was not usually regarded as a poison. A medical man found 103 grains of oil of wormwood in the stomach. In his opinion that amount was more than sufficient to cause death, and he regarded the stuff as a poison. The jury returned a verdict to the effect that death was due to an overdose of the oil taken with a view to procure abortion. They recommended in a rider that such a dangerous drug should be scheduled as a poison. The coroner stated that in his opinion it was most reprehensible for the chemist to have supplied such a drug without any directions as to the dose. It seems not altogether impossible that the police and the Pharmaceutical Society might have something further to say in the matter.

Romance of Poisoning.

Mr. Edgar Saltus has an article in the July number of *Harmsworth's Magazine* bearing the title: "The Romance of Poisoning: Beautiful Women and Accomplished Men who regarded Murder as an Art," which is necessarily interesting to all medical men. The author opens his communication with a characteristic twentieth-century sentence: "Poisons may be toxicoloquially catalogued as triply fascinating." And his reasons for this artistically-expressed opinion are given by him as follows: "Firstly, because of the mystery of them; secondly, because behind the mystery loom the great figures of the Borgias and the Brinvilliers; and, finally, because they involve the whole subject of murder considered as an art." There was a great deal of art, too, mixed up with the records of such transactions in the days when imagination reigned everywhere, and scientific doubt and scientific experiment were the most dangerous and most persecuted enemies of orthodoxy. The ring and poisoned needle of Pompeian antiquity, and long afterwards associated with Borgian reputation, by means of which "those who liked gave a little prick to those they did not like, and the latter fell dead"—have evaporated in the sunbeams of modern science. Such, we have been told, was the practice of Cæsar Borgia, who shook hands more energetically with his foe than his friend, by which action the minute, sting-like needle scratched the skin, and all was over this side the grave—for the victim. Very thrilling mythology that! It make the literature of the subject most attractive, especially to juvenile readers—particularly to those of the female persuasion. The "Aqua Tofania" possesses the historic merit of being a possibility. The judiciously-baptised "Poudre de Succession" runs on parallel lines. Some asserted that this important preparation consisted of ground glass. The poisoning and counter-poisoning of Sainte-Croix by the Marchioness of Brinvilliers and her husband make entertaining reading—of romance. There were many and artistic specimens of such romance prepared about the Courts of "Good Queen Bess" and "la Grand Monarque." Catharine de Medici and the Countess of Somerset scored high on this record of "romance."

The Annual Dinner of the Children's Society.

Among all the numerous learned societies connected with the medical profession none shows greater vitality and promise than the Society for the Study of Diseases of Children. Their annual dinner was recently held at the Hotel Cecil, when Dr. Henry Ashby, of Manchester, presided over a party of about a hundred members and visitors. The Honorary Treasurer, Mr. Clement Lucas, announced that Mr. Charles Wightman, Chairman of the Evelina Hospital, had offered the Society the sum of twenty pounds per annum for the purpose of encouraging original work. A number of capital speeches were given by Mr. A. H. Tubby, Dr. Page May, Dr. George Carpenter, Mr. Sydney Stephenson, and others. A novel feature in this kind of entertainment was the presence of several lay hospital governors, one of whom contributed a highly humorous speech. It is satisfactory to note that the funds of the Society are in a most satisfactory condition, taking into consideration the fact that the Society itself has hardly yet passed from the period of infancy into that of childhood.

PERSONAL.

Mr. Michael Henry Taylor, J.P., L.R.C.P.Ed., of Richmond, has been appointed Coroner for the Kingston division of the county of Surrey.

Dr. Sansom having resigned the Physiciancy, has been appointed Consulting Physician to the London Hospital, and has been unanimously elected by his colleagues a member of the London Hospital Medical Council.

Mr. R. Henslowe Wellington, M.R.C.S.Eng., has been appointed Deputy Coroner for the City and Liberty of Westminster, and for the South-Western district of London.

The monument raised to the memory of Professor Pasteur at his native town Dole, France, was inaugurated on Sunday by an imposing fête *au bienfaiteur de l'humanité.*

On the expiration of his term of office as President of the British Medical Association, Mr. Walter Whitehead, of Manchester, will be succeeded by Dr. J. D. Griffiths, of Swansea, at which place the next annual meeting will be held.

Mr. J. W. K. Mullen, L.R.C.P.I., Medical Superintendent of the Ladywell Sanatorium, has been presented by the nurses and servants of that institution with a study chair to commemorate his completion of twenty-one years' service thereat.

The resignation of Dr. Sansom leaves Dr. Stephen Mackenzie Senior Physician to the London Hospital. He has been obliged to winter in Egypt for the last two years. Should he be obliged to resign his post on account of his health, the medical side of the hospital would receive a serious loss in its teaching capacities.

Professor McHardy, of King's College Hospital, has had a narrow escape from drowning. From a newspaper report it seems during a recent gale in the Channel he fell overboard from a 10-ton yacht in which he was cruising with a friend. The latter went after him in a dinghy, and at length succeeded in getting him back on the yacht after a prolonged immersion.

THE BRITISH MEDICAL ASSOCIATION IN MANCHESTER.

The Manchester meeting, in spite of the autumn-like character of the weather and the lack of attractive features in the noisy, grimy, but enterprising city, has proved eminently successful. About fifteen hundred members are said to have attended. The majority, of course, came from the immediate neighbourhood. The number of foreign delegates was very small. Comparatively few ladies from distant parts of the country availed themselves of the opportunity of visiting this busy Lancashire centre. But Manchester is not a garden city and makes no claim to be a health resort. Mr. Walter Whitehead filled the office of President with grace and tact. The various committees have done their utmost to provide for the convenience and comfort of strangers. Much private hospitality was extended to visitors. The extensive buildings of the Owens College provided ample and excellent accommodation for the various sections. The entertainments and excursions were numerous and afforded much pleasure and delightful opportunities for renewing old friendships.

THE ANNUAL SERVICE AND SPECIAL ADDRESSES.

A special service was held in the Cathedral on Tuesday morning, July 29th, when an eloquent sermon was delivered by the Right Rev. Bishop Thornton, D.D., Vicar of Blackburn, from the text, "Neither shall there be any more pain, for the former things have passed away." A service was also held in the Church of the Holy Name, when the Rev. Charles Coupe, S.J., M.A., preached from "Honour a physician according to thy need of him, with honours due unto him."

Mr. Walter Whitehead delivered the Presidential address before a brilliant audience in the Whitworth Hall on Tuesday evening, July 29th, and dealt with Manchester's early influence on the advancement of medicine and medical education.

Sir Thomas Barlow's address (of which a full abstract will be found in another column) in Medicine was much appreciated, and ably sustained his contention that the study of the natural history of disease must afford the true basis for all advance in treatment.

Dr. Japp Sinclair gave the address in Obstetrics on "Carcinoma in Women," an abstract of which will be found on page 132.

THE SECTIONS.

No very startling discoveries or suggestive discussions can be credited to the Manchester meeting. Much that was interesting and excellent was brought forward in the seventeen sections, but nothing which can be regarded as epoch-making. The division into sections is desirable and necessary, but the tendency to specialise unduly is in many ways detrimental, and it must be admitted that the country practitioner and busy medical man of our towns and cities is unable to obtain a ready knowledge of the best work of the year by attending so sectionised a conference. Much needs to be done to reorganise the work of the Association as a serious scientific body. We consider it most desirable that at least a full abstract of everything presented in the sections should be made available to every member before the meetings. No paper or address should be allowed which has not first been printed in part or in whole. This might easily be arranged without seriously increasing expenses. At the present time there is undoubtedly a great need for concentration of thought and a more concise and precise mode of expression and certainly a more rigorous application of the time limit. It would be well also if opportunity could be given for clinical and practical demonstrations. It is interesting to note the growing number of medical women attending some of the sections. The discussions have gone far to show that in medicine there is "nothing new under the sun." In many instances the subjects selected were of not more than general interest.

In the Medicine Section Professor Clifford Allbutt opened a valuable discussion on the causes, diagnosis and principles of treatment of dilatation of the stomach, by a paper, a summary of which we print in another column; Sir William Broadbent, Professor Musser, of Baltimore, Dr. T. D. Savill, Dr. Harry Campbell, Dr. A. R. Parsons, Sir W. Mitchell Banks and others took part in the discussion.

Dr. N. Bardswell contributed an interesting paper on dilatation of the stomach in cases of pulmonary tuberculosis. Professor Carl von Noorden dealt with the dietetic treatment of chronic granular kidney. A discussion on the differential diagnosis of functional and organic paralysis was opened by Dr. Buzzard. Numerous papers were presented. A special feature of this section were demonstrations of clinical apparatus and methods of research. Clinical cases were also shown. Mr. Hastings Gilford had an excellent exhibition of photographs illustrating infantilism and senilism.

In the Surgery Section the treatment of inoperable cancer gave rise to a very interesting discussion. Mr. Henry Morris, in a very comprehensive paper, opened the subject, and considered the relative advantages of operative procedures, toxin treatment as by Coley's fluid, injections of cancroin, cholesterine with soap, Beatson's method of oophorectomy combined with thyroid feeding, and physical applications such as Finsen light, X-rays, and high-frequency currents. Mr. Thomas Bryant, Dr. Beatson, Professor Wild, Mr. Jessett, Dr. Herbert Snow and others took part. The discussion on the treatment of tuberculous disease of the testis vesiculæ seminales, prostate, and bladder was very ably opened by Sir Thomas Myles and Professor Senn, and Messrs. Edmund Owen, Rutherford Morrison, and Jordan Lloyd were among those who took part. A number of important papers were presented.

In Obstetrics and Gynæcology Dr. Galabin opened the discussion on Cæsarean section, and Dr. Berry Hart on the operative treatment of prolapsus uteri. Many valuable papers were also read.

The Public Medicine Section offered a most attractive programme, including such matters as vaccination, return cases of scarlet fever, the prevention of tuberculosis, arsenical poisoning, and the relation of poverty to disease.

The Psychological and Anatomical Section was naturally very select, but dealt with matters of much importance. Sir John Sibbald opened the discussion on the treatment and care of persons in the early stages of unsoundness of mind. Dr. Mott dealt with the influence of syphilis as a cause of insanity.

In the Physiology and Anatomy Section Dr. Berry Hart opened a valuable discussion on the development of the human genito-urinary organs.

In the Pathology Section Dr. Frederick Mott dealt with the pathology of nerve degeneration, and Professor Sims Woodhead opened a discussion on the place of bacteriological diagnosis in medicine. The relationship of human and bovine tuberculosis was discussed by Professor Hamilton, and that of fœtal bone disease by Dr. Ballantyne and Dr. Stoeltzner at a joint meeting of this section with that devoted to diseases of children.

The Section on Ophthalmology dealt with the treatment of sclero-keratitis, functional derangements of the eye, and the rarer forms of optic atrophy. Many papers were also presented.

In the Section on Diseases of Children the discussion opened by Professor Rotch, of Harvard University, on the modified milk aroused much interest. Considerable attention was given to the question of the treatment of mentally feeble children, and an exciting discussion took place over the value of physical exercises in disease of the respiratory tract.

In Laryngology the question of foreign bodies in the upper air passages received attention, and much discussion ensued on the ultimate results of radical operations on the maxillary and frontal sinuses. A joint discussion with the section on otology took place on the ætiology and treatment of ethmoidal and sphenoidal suppuration.

The Section on Otology discussed the aims and limitations of intra-nasal surgical procedures in the treatment of chronic non-suppurative middle-ear disease, and the indications for and against ligation of the internal jugular vein in cases of otitic pyosepticæmia. Numerous papers were also considered.

In the Dermatological Section a valuable discussion took place on radiography, X ray treatment, high frequency currents, and light treatment.

In the Section on Pharmacology Sir Lauder Brunton opened a discussion upon the undesired and unexpected actions of medicines, including tolerance and idiosyncrasy to or abnormal results from ordinary doses. The therapeutic value of arsenic was also considered.

Much good work of a somewhat technical character was accomplished in the Section dealing with industrial hygiene and diseases of occupation. Dr. John Shoemaker, of Philadelphia, took an active part in the discussion in this Section.

The Section on Ethics proved a safety valve for iconoclastic progressives and enthusiastic reformers, and many vigorously-worded resolutions were submitted. Such burning questions as contract practice, medical education, hospital reform, medical organisation, and vaccination aroused warm discussion.

Much quiet but good work was also done in the sections devoted to Navy, Army and Ambulance, and Tropical Diseases.

We regret that lack of space prevents our giving a detailed account of the proceedings, but abstracts of many of the more important contributions we are providing for our readers:

THE PATHOLOGICAL MUSEUM.

A small but interesting collection of drawings, photographs, and specimens were shown in the pathological laboratories. A useful catalogue had been compiled by Dr. Moore. Among the more important preparations were those of Dr. Stoeltzner, illustrating fœtal and infantile bone disease; Mr. G. A. Wright, showing changes in tuberculous disease of the hip; Mr. Noble Smith's plates of congenital displacement of the hip-joints; Drs. Orr and Rows, specimens of nerve-cells of spinal root ganglia. Mr. Southam showed an interesting series of fifty cæcal appendices; Dr. Chalmers Watson exhibited photographs illustrating some results of an experimental research on the comparative pathology of gout. Prof. Delepine showed photographs of lesions found in patients and rats suffering from chronic arsenical poisoning; and Mr. Jonathan Hutchinson had sent some valuable portraits admirably indicating the characteristics of arsenical keratosis and arsenical cancer. Mr. Westmacott made a good show with his preparations illustrating the anatomical characters of the nasal cavity and accessory sinuses.

It is to be regretted that more of the very valuable material locked up in the Pathological Museum of the Owens College was not made accessible to members.

A special feature was the very interesting collection of drawings which Mr. Hutchinson had selected from those added to the London Polyclinic Museum during the past year. It would add much to the value of the annual pathological show if Mr. Hutchinson's example could be followed by workers throughout the country.

SPECIAL EXHIBITIONS.

It is to be regretted that the various departments of the Medical School of Owens College did not arrange for exhibitions of apparatus and materials connected with their special work. Professor Stirling was, however, an exception, and provided an excellent and most interesting exhibit of some illustrated classics, specimens illustrating the methods of teaching physiology, tracings, and physiological apparatus.

Mr. Hastings Gilford exhibited a series of pictures and photographs illustrating infantilism and senilism.

There was also a special photographic exhibition, but the majority of the exhibits were of no medical interest.

THE HANDBOOK AND GUIDE.

The volume presented to members and prepared under the directions of Mr. Ray is deserving of high praise. It forms a handsome, admirably illustrated work of over 200 pages. Almost all features concerning Manchester and its immediate neighbourhood receive consideration. The section dealing with the Manchester Medical School has been written by Professor Stirling, while the medical charities are described by that veteran physician Dr. Renaud.

ENTERTAINMENTS AND EXCURSIONS.

Although Manchester is by no means an ideal situation for a picnic, and in spite of much that was unsatisfactory in last week's weather, the festive, frivolous, and social side of the annual gathering has been perhaps more successful than the purely scientific. Numerous garden parties have taken place. Special mention may be allowed to that of Mrs. Rylands, the munificent founder of the far-famed Rylands' library, where the company was much charmed with the pastoral play provided by members of Mr. Benson's Shakespearean Company. Another worthy of note was that given by Dr. and Mrs. Mould at the Royal Asylum, Cheadle.

During the week interesting excursions took place to Blackpool, Crewe, Northwich, Bury and other centres. The evenings were devoted to entertainments which took the form of a soirée at Owens College, an illuminated fete at Whitworth Park, a variety entertainment at the Prince's Theatre, a conversazione at the Art Gallery, and a reception at the Town Hall.

The annual dinner was provided in a specially-erected marquee, which also afforded somewhat novel accommodation for a ball, which concluded a most enjoyable and successful gathering.

Saturday, August 2nd, was given up to excursions to Chatsworth and Haddon Hall, Southport, Windermere, Lancaster, Chester, Colwyn Bay and Conway, Llanberis, Snowdon and Carnarvon, which however were much marred by unfavourable weather.

SOCIETY MEETINGS.

During the week various important gatherings took place in connection with different societies. Thus meetings were held in the interests of the New Sydenham Society, the Irish Medical Schools and Graduates' Association, the Police Surgeons' Association, and the British Electro-Therapeutic Society. Members of the Anglo-American Continental Medical Society lunched together. An international golf match was also held. A number of Manchester clubs extended the use of their premises to members of the Association.

MANCHESTER HOSPITALS.

The various hospitals were open for inspection during the week.

The Royal Infirmary is an antiquated and altogether inadequate building, and most of the Manchester hospitals are lacking in many of the desirable modern features. Even the new St. Mary's Hospital for Women and Children has been built on a particularly unsuitable site. Manchester has but little to teach in regard to hospital construction and much to learn.

The general arrangements for the convenience of visitors were on the whole very good. The accommodation for ladies might have been improved with advantage, and that for representatives of the Press very deficient. At the general meetings a number of undergraduates in their becoming gowns did good service as stewards. It may also be noted that the Manchester papers gave great prominence to the work of the Association.

ASSOCIATION NOTES.

On Monday evening, July 26th, Mr. Walter Whitehead entertained a number of guests at dinner at the Albion Hotel.

Sir Thomas Barlow, the deliverer of the address in medicine, is claimed by Manchester men as an old Lancastrian and former student of Owens College.

The Lord Mayor of Manchester has taken an active part in welcoming the members of the Association to the city of which he is chief magistrate.

The works of the Corporation, the Ship Canal, many factories, and other places of local interest have been freely thrown open to members.

Among the foreign guests were such well-known men as Professors Babinsky and Liebreich, of Berlin; Von Noorden, of Frankfurt; Ludwig, of Munich; Musser and Anders, of Philadelphia; Northreys, of New York; Onodi, of Budapest; Pepper, of Philadelphia; and Rotch, of Boston.

The purely business meetings were almost devoid of interest. Mr. Francis Fowke, general secretary of the Association for thirty-one years, has resigned and been accorded the honour of honorary membership for his distinguished services. Mr. Guy Elliston has been appointed his successor. Mr. Andrew Clark has been appointed Chairman of Council. Dr. Markham Skerritt, of Bristol, has been appointed the new Treasurer of the Association.

Sir Victor Horsley, F.R.S., presided over a largely attended breakfast on Thursday, July 31st, given by the National Temperance League. Professor Sims Woodhead and others took part.

The annual meeting for 1903 is to be held in Swansea, and Dr. Thomas Dryslwyn Griffiths is President-Elect.

In connection with the museum we may express a hope that in future the custom of "showing" specimens of whiskey may be stopped, and the American method of touting their goods ameliorated.

It is to be hoped that under its new constitution the British Medical Association will not only extend its usefulness to members, but will do much to maintain the dignity and position of the profession throughout the Empire.

THE EXHIBITION OF DRUGS, INSTRUMENTS, &c.

The exhibits on the present occasion were exceptionally large and varied, Manchester itself having contributed a not inconsiderable share. The exhibition was held in the Drill Hall, near to Owens College, of which we propose to give a brief description in our next issue.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

MANCHESTER.

[FROM OUR OWN CORRESPONDENT.]

The Medical Guild and the Meeting of the British Medical Association.

The preparations for the great meeting have culminated in what our visitors have been kind enough to describe as a brilliant success. Everyone has behaved well with the exception of some person or persons unknown who had the bad taste to distribute copies of the *Medical Guild Quarterly* within the Owens College to those who attended the President's Address and the Soirée which followed it last Tuesday evening. Ladies and laymen were present in large numbers, and the occasion and place were hardly suitable for the perusal of medico-political "illiterature." The editor of the *Quarterly* remarks in the current number:—"Indifference or dislike to be associated with certain other members, or an objection to the fetters of any combination, must be the causes that keep men outside the Guild." The men who have been kept outside the Guild and who have recently left it, would appear to have displayed good judgment, although the editor maintains that "From the Guild has emanated an unseen influence that has worked for all that is noble, true, and honourable in the profession." He more truthfully continues: "The Guild has a greater work before it in the future than it has accomplished in the past.

The business of the Guild at its last quarterly meeting appears, from the report in its journal, to have been the passing of a resolution censuring the much discussed pamphlet signed by the medical staff of the Manchester Maternity Hospital. The distribution of this report at a function where laymen and ladies were present, was surely a blow so much below the belt as to be unworthy even of warriors in medico-political warfare. The report of the June meeting of the council of the Guild contains a reprint of an advertisement published in the *Manchester Guardian* on behalf of the authorities of the Owens College. This seems to have exercised the fourteen councillors present, because the names of two distinguished physicians were mentioned in connection with two post-graduates courses which were announced. The secretary of the Guild was requested to communicate with the two physicians upon the subject. Their answers to his communications will be worth reading—if indeed they answer them at all. The Guild is indeed fallen low when it not only insults the Owens College, but goes the length of distributing copies of the insult to the foreign, colonial, and other visitors of the College, actually within the walls of the College.

On a well-known estate in Scotland the proprietor had the words "Thou God seest me" printed on notice boards, instead of the more usual "Trespassers will be prosecuted." He did not shoot, nor did his visitors, so that the absence of game from his estate did not seriously inconvenience him. The unseen silent guiding hand of Conscience seems to pull too lightly on the strings that move the Medical Guild. This being so, a little unpleasant notoriety may help the "unseen influence" that "emanates" from the Guild to mind its own business more successfully, and leave alone "all that is true and noble and honourable in the profession."

LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

Medico-Psychological Association of Great Britain and Ireland.

The sixty-first annual meeting of this Association was held at the Medical Institution, Liverpool, on Thursday and Friday, July 24th and 25th, under the presidency of Dr. J. Wiglesworth, Rainhill. At the commencement of the meeting Dr. Sydney Coupland, M.D., F.R.C.P., Commissioner in Lunacy, London, and Dr. Edward N. Bush, M.D., Medical Superintendent of the Sheppard

Pratt Hospital, Towson, Maryland, were unanimously elected honorary members of the Association.

Dr. Wiglesworth, in a comprehensive and interesting address, dealt specially with some of the problems of heredity in regard to mental diseases. It was impossible to take all the cases that had come under his care, yet he quoted figures dealing with heredity and insanity during the last twelve years, and out of 3,445 cases definite hereditary taint had been found in 965. Females showed a higher percentage than males, and the mother had a greater tendency to transmit insanity to her female offspring than to her male. Alcoholism was a fruitful cause of insanity, incompatibility of parents another, and, he went on to say, if any advance was to be made in the improvement of the race it must be by a recognition of the enormous importance of the subject by parents and guardians, as well as by young people.

Mr. Damer Harrison read a paper, "Some Remarks upon the Surgical Treatment of Insanity," and enumerated a number of cases in his own experience which had been treated surgically with success. The Chairman congratulated him on the brilliant results he had achieved.

Dr. Mercier proposed the following resolution "That in the opinion of this Association further legislative measures are needed to protect the property of those who, without being certifiably insane, are yet, by reason of disorder of mind unable to administer their affairs with ordinary prudence." His object, he said, was to get legislation on this important subject embodied in the new Lunacy Act. The absolute number of cases was not large, but still it was sufficiently so to justify legislation, and in the individual cases that had come under notice the hardship and misery produced was very great indeed. The important point was what remedy were they to recommend. Dr. Mercier's remarks were followed by a speech on the same subject by Mr. Percy Becher, solicitor, London, in the course of which he stated that continental countries recognised the fact that there existed a class of people, who, without being exactly of disordered intellect, nevertheless stood in need of some help and some protection in the management of themselves and their affairs. He was of opinion that legislation should not be under the Lunacy Department so that people, who, either voluntarily or by order of the court, had their affairs taken out of their hands should not be branded as lunatics. A discussion followed, and the resolution was subsequently passed.

Dr. F. W. Mott contributed a paper entitled "Stimulus in Relation to Decay and Repair of the Nervous System." The paper was illustrated by lantern slides and diagrams, and Professor Sherrington, Dr. W. B. Warrington, and others took part in the discussion that followed.

Dr. A. W. Campbell and Dr. David Orr each gave a lantern demonstration on the medullated nerves fibres of the cerebral cortex, and nerve-cell and medullated fibre changes in acute insanity, respectively.

Dr. T. S. Clouston introduced a discussion upon "The Possibility of Providing Suitable Means of Treatment for Incipient and Transient Mental Diseases in our great General Hospitals," in which, amongst others, the following eminent authorities took part:—Sir John Sibbald, Drs. Wiglesworth, Hayes Newington, Mercier, Rayner, Savage, Hyslop, Yellowlees, Percy Smith, and Urquhart.

A paper on "Medico-Psychological Statistics—the Desirability of Correlation with a View to Collective Study," was read by Dr. Hubert C. Bond; and Dr. W. R. Dawson read "Notes on the Pathology of Diabetic Insanity."

The annual dinner of the Association was held on the Thursday evening at the Adelphi Hotel, Dr. Wiglesworth presiding. The toast of "The Medico-Psychological Association" was given by Mr. W. Scott Barrett and acknowledged by the President, who remarked that the Association was making steady progress, although it might be slow, and that never before had the membership been so numerous, nor had it ever possessed so much vitality. The toast of "The Liverpool University College" was proposed by Dr. Savage and responded to by Professor Sherrington. Dr. Yellowlees gave "The Medical Profession of Liverpool," to which Sir William Mitchell Banks replied. The concluding toast, "The Guests," was proposed by Dr. Clouston and acknowledged by Sir E. R. Russell, Dr. Brush (Baltimore), and Mr. Edgar Browne.

Dr. Wiglesworth, the President, and Mrs. Wiglesworth kindly invited the members to a garden party on the Saturday following the meeting at Rainhill Asylum, near Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE Liverpool School of Medicine under the able and generous guidance of its enthusiastic chairman, Sir Alfred Jones, invited the tropical section of the British Medical Association to dinner on Friday at the Adelphi Hotel with the Duke of Northumberland as their guest. Among those present we observed the Bishop of Liverpool, Sir Wm. Macgregor, K.C.M.G. (Governor of Lagos), Sir George Denton, K.C.M.G. (Governor of Gambia), Sir Wm. Kynsey, C.M.G., Sir Wm. M. Banks, Sir Ed. Russell, Major Ronald Ross, C.B.; Professors Clifford Albutt, Chiene, Madden, Sherrington, Boyce, and Rushton Parker; Drs. Stoeltzner, Manson, C.M.G., Daniels, Carter, Dawson, Adams, &c., &c.

After the toast of "The King" the Chairman proposed "The Duke of Northumberland," remarking that "our" distinguished guest had encouraged the promotion of a Tropical School of Medicine in its infancy, as his presence that night proved. Tropical medicine must benefit every nation of the world, and England was glad to combine with other nations in making life in the tropics more salutary. Liverpool, he thought, had come to the front in this matter, and his Grace was not without merit in this success, as he had rendered substantial aid in their first efforts.

The Duke, responding, said he was deeply impressed with the importance of ameliorating tropical existence, as we had large tracts of land almost uninhabitable at present. What the possibility of our future would be if these districts were made salubrious time alone would solve. The warrior, colonist, and diplomatist had done their several duties in the past, but it yet remained for medical science to complete the victory. He congratulated Liverpool on its magnificent school of medicine, more especially its youngest and most vigorous branch, which had a brilliant future before it. It was also pleasing to see the commercial generosity extended to it by business men, who were not wholly disinterested in the development of these barren possessions. It was satisfactory to know that the institution had sent out six or seven expeditions to various parts of the world, whose devotion he admired in facing such dangers in the cause of humanity. Personally, he owed a debt of gratitude to Major Ross who first awakened his own interest in the subject by a lecture he gave at the Royal Institution, over which he presided.

The Bishop of Liverpool next proposed "Tropical Medicine," to which Sir Wm. Kynsey responded.

Dr. Manson believed that all countries could be made healthy when the true cause was known and expense ignored. He deplored the lack of financial support these noble institutions suffered from, and believed that the investigations carried on in London and Liverpool must ultimately bear good fruit. Malaria was not the only disease, as many others existed of which we were perfectly ignorant, as he had seen to-day in the Liverpool School a discovery by Dr. Dutton which was the probable cause of a hitherto unknown tropical disease, and was of infinite scientific importance. He was in favour of a Government department that included tropical medicine as well as the education of the natives of the country, showing them how to cure and prevent the disease.

Professor Clifford Allbutt described work done at Cambridge and other Universities.

The Chairman proposed "Our Tropical Colonies," and offered medical men, with his usual generosity, free passes and free access to all their stores on the coast if they would only take this matter in hand. After a few remarks by his Excellency Sir Wm. Macgregor, K.C.M.G., and Sir G. C. Denton a very instructive evening was concluded with a cordial vote of thanks to Sir Alfred Jones for his handsome reception.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

SUNSTROKE AND DIETARY.

To the Editor of The Medical Press and Circular.

Sir,—The "microbic" explanation of sunstroke is by no means a clear solution of the problem of its incidence, and therefore while I quite agree with your characterising the claim of the man who went about for a few hours in the hot sun and escaped sunstroke because he was "a vegetarian" as being faddist nonsense, yet the relation of food and drink to such curious diseases as sunstroke is worthy of more than passing comment.

I was very much struck in India with the fact that men and women of the poorer classes, with their cranial bones and smooth fine hair brushed close down to the head, went about in the fierce sun with impunity at times when well-fed Indians and Europeans found it necessary to carry an umbrella as well as a sun helmet.

Their almost complete abstention from alcohol, the small amount of fluid they drank, and the sparing simplicity of their dietary had some share in this result, for it was just in these points that they differed from those who found the heat more dangerous.

Abstinence from flesh food alone certainly could not claim the credit, because Mahomedans and Rajpoots as well as Hindus of the flesh-abstaining castes seemed equally immune.

Is it not equally instructive to note that animals in their natural hardy state seldom die of sunstroke, whereas, among those animals such as highly-fed horses, that have had much fluid food, we find most cases of death from this cause.

Where the tissues are over-full of fluid one can understand that they would be likely to be more readily affected by extreme heat variations than when they were in a drier and harder condition.

From this point of view, both fruitarianism and total abstinence are good, in so far as they encourage habits of drier feeding and less fluid imbibition.

I am, Sir, yours truly,
Josiah Oldfield, D.C.L., (Oxon.), M.R.C.S.E.
Harley Street, W., August 2nd, 1902.

[We fail to see on what grounds does Dr. Oldfield assert that sunstroke is common in horses. The theory about fluid food is purely conjectural, and simply substitutes water for vegetables as a preventive of suntroke.—Ed.].

Royal College of Surgeons in Ireland.

The following scholarships and prizes have been awarded for the summer session, 1902:—

Barker Anatomical Prize: £30, R. G. Allen.

Carmichael Scholarship: £15, J. J. Connolly.

Silver Medals in Operative Surgery: W. R. Ormsby and J. J. Ryan (equal).

Practical Histology: W. W. Boyce, First Prize, cheque and medal; A. C. Adams, Second Prize, cheque and certificate.

Practical Chemistry: C. M. Burton, First Prize, cheque and medal; J. B. Kelly, Second Prize, cheque and certificate.

Public Health and Forensic Medicine: F. O'D. Fawcett, First Prize, cheque and medal; L. F. Kelly, Second Prize, cheque and certificate.

Materia Medica: P. V. Dolan, First Prize, cheque and medal; H. S. Misstear, Second Prize, cheque and certificate.

Practical Pharmacy: C. M. Burton, First Prize, cheque and medal; R. J. Smallman, Second Prize, cheque and certificate.

Biology: C. M. Burton, First Prize, cheque and medal; A. J. Faulkner, Second Prize, cheque and certificate.

The schools of surgery will resume work after the summer recess, October 1st.

Odontological Society of Great Britain

The following office-bearers have been elected for 1902-1903: President: William A. Hunt. Vice-Presidents: (Resident) F. J. Bennett, W. H. Woodruff, E. G. Betts. (Non-Resident): W. S. Woodburn, Glasgow; W. B. Bacon, Tunbridge Wells; H. B. Mason, Exeter. Treasurer: C. F. Rilot. Librarian: H. Baldwin. Curator: J. F. Colver. Editor of Transactions: H. Lloyd Williams. Honorary Secretaries: J. H. Mummery (Foreign), W. Rushton (Council), Montagu F. Hopson (Society). Councillors: (Resident) R. Wynne Rouw, J. Mansbridge, Morton A. Smale, R. Dennison Pedley, J. Percy Smith, George Hern, A. Hopewell-Smith, E. Preedy, Carl Schelling; (Non-resident): G. O. Whittaker, Manchester; W. A. Rhodes, Cambridge; W. Glaisby, York; J. J. H. Sanders, Barnstaple; E. A. Bogue, New York; J. F. L. Pike, Sheffield; G. W. Watson, Edinburgh; Kevin E. O'Duffy, Dublin; John E. Grevers, Amsterdam.

The Conjoint Board of Scotland.

The following candidates have passed the respective examinations by the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow:—

First Examination (five years' course).—Of twenty-nine candidates entered the following eight passed the examination: Horace Moody, Angus Cameron Mackay, Eleanor Margaret Thompson, Thomas Mayne Reid Waddell, Thomas McLaren Galloway, William Barclay, Thomas Wren Faulkner (with distinction), David James Melville Legge, and four passed in physics, six in elementary biology, and four passed in chemistry.

Second Examination (four years' course).—Of six candidates entered the following three passed the examination: Charles Joseph Sutton, Edward Henry Smyth, and John William Duncan.

Second Examination (five years' course).—Of twenty-nine candidates entered the following seventeen passed the examination: Alan Cunliffe Vidal, Ernest Patrick Titterton, Tom Newman Darling, William Montgomery Johnston, Joseph Millar Gordon Ewing (with distinction), John Samuel McLean, Colin Garner, Bertram Ingram, Robert Percy Hosford, Henry Alexander Hagenauer, James Sullivan (with distinction), Charles Stewart Parnell McDermott, Ayodeji Oyejola, Michael Philip Desmond, John Macmillan Campbell (with distinction), James Young (with distinction), and Henry Edward Bolton, and two passed in anatomy.

Third Examination (five years' course).—Of thirty-two candidates entered the followning twenty-one passed the examination: Jehangir Horsnasji Contractor, Arthur Joseph O'Leary, Thomas Bunnett Lewers, Rupert Allen Clayton Rigby, Peshotan Ratanji Sataravala, Hubert James George, Edward Rainsford Mumford, Lilian Mary Grandin, Sybil Lonie Lewis, George Morley Arundel Thomas, Joseph Stark Forth (with distinction), William Herbert Boalth, Jamshed Dadabhai Munsiff, John St. Aubyn Maughan, Broderick Edward Middleton Newland, Edward Percy Airth Richardshon, John O'Brien, Elizabeth Mary Cardozo, William Lang Hodge, John Joseph Lawton, Robert David Hirsch, and one passed in Materia Medica.

Final Examination.—Of sixty-nine candidates the following thirty-seven passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.&S.G.: James Campbell MacLean, Charles Isaacs Levey, Frederick Llewellyn Thomson, M.D., John William Isbister, Sophia Frances Hickman, David Moodie, Frederic John Scrimgeour, Robert Bathgate Johnston (with honours), Philip Gray-Marshall, May Thomson, Robert Douglas Argyll Douglas, Peter Mohan, Henry Anderson Lunn, William Bates, Donald Grant, William Samuel Rainey Dick, Arthur John Beardmore, Tithal Narayan Patwardhan, Harold Raby Parkinson, Robert Patrick Hal Blackstock, William John Gray, William James Noble Todd, L.D.S., Shanker Bhawoo Kulkerni, Mutyala Sriramulu Naidu, Lewis Pemberton Anderson, Percy Howe, Joseph William Sutton, Pandit Devi Dayal Sasun, Khubchand Menghraj Manghirmalani, William Deery, Henry Graham Arnott, M.D., Hirabai Furdoonji Banaji, Alexander Watson Hart, John Buckner, William Gregory Neill Keith, St. Clair Grahame Ballenden, and John Walker Wood; and five passed in Medicine and Therapeutics, one in Surgery and Surgical Anatomy, six in Midwifery, and seven in Medical Jurisprudence.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c, Much confusion will be spared by attention to this rule.

Our Paris correspondent's letter arrived too late for insertion this week.

X-Ray Photographer (Tunbridge Wells).—The essence of the whole thing is slow development. There is no advantage in having specially rapid plates. Any good quick plate may be used, but as the development is slow the greatest care must be taken with regard to the light used in the dark room. Indeed, it will be far the safer plan to carry on the process as far as possible in absolute darkness. All X-ray plates may be regarded as over-exposed.

THE KELTY CASE.

To the Editor of The Medical Press and Circular.

Sir,—I have read in your issue of July 30th a short report of this case to recover balance of the price of a good will of a medical practice. I am surprised that such an action should have been necessary; it has been decided in a still higher court that these contracts are not capable of being made the subject of "decrees for specific performance." But the doctors as a *class* are gainers by the decision before the Lord Chief Justice.

I am, Sir, yours truly,

An Observer.

Theodore F.—The gentleman you mention is usually positive in his opinions, but it by no means follows that he is always right. Indeed, many who are qualified to judge maintain that the reverse is very often the case. We should advise you in your relation to patients to steer as far as possible a middle course. Where your mind is made up as the result of careful investigation and weighing of facts, say so clearly and firmly. Be cautious, however, when your statement is founded, as it necessarily must often be, upon empiricism pure and simple. Study the writings of a man like Paget if you wish to master the art of reasoned statement with an absolute regard to its value relative to the fulness of the underlying basis of ascertained facts. Keep a few guiding principles in view, and in the course of time you will find the methods of clear reasoning and clear expression will become a kind of second nature.

MURPHY'S BUTTON.

To the Editor of the Medical Press and Circular.

Sir,—May I trouble you for the favour of a line in your next issue stating who is the Murphy whose name is attached to the phrase "Murphy's button?" and oblige,

Yours respectfully,

One of the Same Name.

[The Murphy whose name is given to the famous "button" used in intestinal anastomosis is an American surgeon, whose full name and description our correspondent will with this clue have little difficulty in ascertaining.—Ed. Medical Press and Circular.]

Appointments.

Broadbent, John, M.A., M.D.Oxon., M.R.C.P.Lond., Assistant Physician to the London Fever Hospital.

Burton, Arthur, M.D.Cantab., Certifying Surgeon under the Factory Act for the Cromer District.

Cox, Ernest A., M.R.C.S., L.R.C.P.Lond., Public Vaccinator for the No. 4 District of the Daventry Union.

Davies, Joseph, F.R.C.S, L.R.C.P.Edin., L.F.P.S.Glasg., J.P., Deputy Medical Officer of Health of Swansea.

Gibson, William, M.B., Ch.B.Glasg., Medical Officer of Health to the Cheadle Rural District Council.

Gough, John Harley, F.R.C.S.Edin., L.R.C.P.Lond., M.R.C.S., Honorary Physician to the Torbay Hospital, Torquay.

Harratt, T. T., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health of Rye.

Haworth, E., M.B., M.S.Glasg., Medical Officer of Health for Oswaldtwistle.

Hopewell-Smith, A., L.R.C.P.Lond., M.R.C.S., L.D.S.Eng., Lecturer on Dental Anatomy and Physiology at the Royal Dental Hospital of London.

Hunt, Ernest, L.R.C.P Lond., M.R.C.S., Medical Officer for the Kingsteignton District by the Newton Abbot (Devon) Board of Guardians.

Long, Sydney Herbert, M.B., B.C.Cantab., Medical Officer of Health to the St. Faith's Rural District Council.

Matthew, Edwin, M.A., M.B., C.M.Edin., Assistant Physician to the Leith Hospital.

Meredith, R. William Henry, L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 1 District by the Wellington (Somerset) Board of Guardians,

Pipette, Walter, L.R.C.P.Edin., L.R.C.S.Edin., L.S A., Medical Officer for the No. 1 District by the Bridgwater Board of Guardians.

Pollock, John Robert Russell, L.R.C.P.Lond., M.R.C.S., Medical Officer of Health of the Tiverton (Devon) Rural District.

Scott, James Andrew Neptune, M.D.Glasg., Health Officer for the Shire of Wycheproof, vice Dr. Ralph Charles Brown.

Seccombe, J. W. S., M.R.C.S., L.R.C.P.Lond., House Physician to St. George's Hospital.

Talbot, Francis T., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., Surgeon to the Stockton and Thornaby Hospital.

Tate, Isobel A., M.B., B.S.R.U.I., Resident Assistant Medical Officer at the Union Workhouse, Burnley.

Taylor, M. H., J.P., L.R.C.P., L.R.C.S., Coroner for the Kingston District of Surrey.

Toye, E. J., M.D.Lond., Medical Officer of Health to the Northam (Devon) Urban District Council.

Valentine, W. A., M.D.Univ. Dublin Trin Coll., District Medical Officer and Public Vaccinator of the Northam District of the Bideford Union.

Wellington, R. H., L.R.C.P.Lond., M.R.C.S., Deputy Coroner for the City and Liberty of Westminster and for the South-Western District of London under the London County Council.

Williams, Penrose Lanyon Watkin, L R.C.P.Lond., M.R.C.S., Medical Officer to the Bridgwater Workhouse.

Vacancies.

Belmullet Union.—Bangor Dispensary District. Medical Officer. Salary £100 a year, with Vaccination Fees, &c., and £10 a year as Medical Officer of Health. Applications to E. N. Flynn, Clerk of Union. (See Advt.).

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum (with an allowance of £30 per annum for cab hire) and furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £130, rising to £160, with board, furnished apartments, laundry, &c. Applications to the Medical Superintendent.

Dundee Sanatorium for Consumption.—Medical Superintendent. Salary £250 per annum. Applications to Thos. Thornton, Hon. Secretary, City Chambers, Dundee.

Gorey Union.—Medical Officer of the Workhouse Fever Hospital. Salary £100 a year. Also a Medical Superintendent Officer of Health for the Rural District. Salary £20 a year. Applications to R. Creighton, Clerk of the Council. (See Advt.)

Halifax Union Poor-law Hospital.—Resident Medical Officer. Salary £130 per annum as Resident Medical Officer and £20 per annum for Dispensing, with apartments, rations, and washing. Applications to Arthur T. Longbotham, Solicitor and Clerk to the Guardians, 4, Carlton Street, Halifax.

Haydock Lodge Asylum, Lancashire.—Assistant Medical Officer. Salary to commence at £175 a year, with furnished quarters, board, washing, &c. Applications to Dr. Street, Haydock Lodge, Newton-le-Willows, Lancs.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist for the Serum Department at Aldenham. Salary £200, with furnished rooms. Applications before September 1st. (See Advt.)

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Furnished apartments, attendance, light, and fuel are provided. Applications to Secretary, Martin Snell Preston, Journal Chambers, Nottingham.

Newport and Monmouthshire Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to the Secretary.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum. Applications immediately to the Secretary, E. S. Baylis, 19, Moorgate Street, Rotherham.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance and washing. Applications immediately to the Secretary.

Tullamore Union.—Philipstown Dispensary District. Medical Officer. Salary £100 a year, together with Vaccination Fees. Applications to E. J. Graham, Clerk of the Union. (See Advt.)

Births.

Baly.—On July 27th, at Goldhurst Terrace, South Hampstead, the wife of C. F. Peyton Baly, M.R.C.S., L.R.C.P., of a daughter.

Phillips.—On July 29th, at 74, Carlisle Street, Cardiff, the wife of J. A. Philips, surgeon, of a daughter.

Turney.—On August 1st, at 68, Portland Place, London, W., the wife of H. G. Turney, M.D., of a daughter.

Marriages.

Griffith—Tweedie.—On July 30th, at Christ Church, Edinburgh, William Starbuck Griffith, M.B., Milford Haven, to Ada Mabel, second daughter of Charles Tweedie, late of Jessore, Bengal.

Hare—Lockwood.—On July 30th, at Christ Church, Linnet Lane, Liverpool, Alfred William Hare, M.B., Ch.B., youngest son of the late Humphrey J. Hare, of Chatham, to Laura Margaret, only daughter of the late John Aitken Lockwood, Liverpool.

Purvis—Raymond.—On July 31st, at St. Mary's, Preston, Yeovil, William Prior Purvis, F.R.C.S., M.D., M.S., of Southampton, to Dora, eldest daughter of Walter Raymond, of Preston, Yeovil.

Savage—Cooper.—On July 26th, at St. Matthew's, Brixton, Thomas Copeland Savage, F.R.C.S., second son of the late Warwick Savage, Esq., of Burslem, Staffs, to Madeline, second daughter of William Cooper, Esq., C.C., 65, Brixton Hill.

Stephens—Smirthwaite.—On July 30th, at Holy Trinity Church, Burnley, John Harding Stephens, M.B., son of the late Henry Stephens, of Knutsford, to Annie Maude, only daughter of the late Dr. S. V. Smirthwaite, of Coal Clough, Burnley.

Deaths.

Lamb.—On August 2nd, at Thorpe Lodge, Shirley, Southampton, of angina pectoris, Surgeon Lt.-Colonel Henry Lamb, R.A.M.C., eldest son of the late Rev. R. G. Lamb, B.A., late Colonial Chaplain, Capetown, aged 64.

Permewan.—On July 26th, at his residence, Chapel Street, Redruth, Cornwall, John Permewan, L.R.C.P.Ed.

Watts.—On August 1st, at 97, Central Hill, Upper Norwood, Deputy Surgeon-General Joseph Watts, late A.M.D. (retired).

Vienna Clinical Lecture.

SPINAL CHANGES IN MUSCULAR DEFECTS.

By PROF. H. OBERSTEINER.

[FROM OUR VIENNA CORRESPONDENT.]

WE find, gentlemen, in Leyden's classical work on "Diseases of the Spine," published in 1875, descriptive examples of partial atrophy of the nerve centres in the spinal column associated with deformities—congenital and accidental—contractions of limbs or malformation of the cerebral mass, such as agenesia or aphasia. The opinions of this author are still to be valued for their accuracy in throwing light on the trophic disturbance in the organ by the wasting that takes place elsewhere.

He also demonstrated the converse that wasting or atrophy took place in the gray matter of the cord when the distal member was disused. Leyden's conclusions were obtained from a very rough survey, and a limited quantity of material at his disposal which have since been supplemented from time to time by other more accurate publications on congenital defects which may be briefly expressed in the words of my colleague, Prof. Redlich, that "Amputations of any kind produce two forms of change in the nerve substance of the cord: 1st, one immediately after the amputation when degeneration and the motor cells are affected, and 2nd, that after the course of a year atrophy and contraction of one-half of the cord takes place. Knowing this, it is necessary to go into other details and localise the position as well as determine the cell group of nerves affected by the removal of any extremity or set of muscles.

The method of experimental inquiry for "axial" or secondary changes have been followed from the anterior horns of the cord to the nerve fibre into the amputated organ resulting from injury, &c., but it requires more care to follow the defect of a muscular group with congenital origin. The results of these inquiries have now resulted in three facts: (1) According to Sano, the anterior horns have each corresponding cell groups to supply. The researches of Bruce in the lumbar region are interesting in this respect, but congenital defects are those which provide us with the most trustworthy evidence. (2) Marinesco holds to the opinion that these cells in the cord supply certain nerves and not particular muscles; while a third opinion, in which Nelis, Neef, and others concur, is that each segment of the spinal cord has a localisation, such as one for the hand, another for the forearm, &c. Too much caution cannot be exercised in this morbid diagnosis. In all congenital cases we expect a nuclear defect in the cells where infantile destruction had existed. In many of the cases of pectoralis defects no changes whatever were found in the anterior horn cells, which agrees with Schlinger's experience.

At the meeting (June 11th, 1901) of the "Vereines für Psychiatrie und Neurologie," Primarino Linsmeyer showed a man, æt. 48, who had congenital atrophy of the right sterno-cleido-mastoideus, the clavicular portion of the right cucularis, pectoralis major except the clavicular portion, the supra- and infra-spinati, and the rhomboidei. The man died shortly after, and Linsmeyer kindly handed the nerve system over to my charge for careful examination, which I did from the fourth cervical to the fifth dorsal inclusive, with 800 sections, and coloured some by Gieson's method, others by Weigert's. I may add that I examined the cord without knowing which of the sides was affected, although I had seen the case some time before, yet I had forgotten which side was affected, and looked upon this as an advantage against any prejudice that might influence the investigation. Unhappily, however, this doubt could not presumably long be concealed, as the first sections showed a great deficiency of cells in the right side. The three upper segments, as well as the medulla oblongata, were examined owing to the defect in the sterno-cleido-mastoid muscle, but nothing special to note was observed; while the cerebral appearance seemed changed in its configuration. The accessorial nerve was cut at several points and examined, but no difference from the opposite side could be observed. This nerve supplies the respiration and extends down to the sixth cervical segment which was supposed to be affected, and no change could be seen in the anterior horn of the cord, neither in its calibre or its section were the fibres of the accessorius affected.

Coming now to the anterior horns in particular, I may say at once that no asymmetry, or more correctly, very little change of symmetry, could be observed, although it must be admitted there was a slight decrease of the affected side when closely examined, which could hardly be valued as a pathological condition. The numbering of the cells was next undertaken, and only in two sections which followed each other were these found markedly to vary, and these again only to be found in one of the groups located in the anterior horns.

Nothing noticeable was observed in the medial group; the dorso-lateral group was distinctly richer on the right side in large cells than that same group in the left side of the cord, and certainly the medio-neutral group of the anterior horn was in no way reduced. The only group by this comparative method of taking right and left in the same subject that could be said to be morbidly affected was the ventro-lateral group, which was confirmed in all of the sections down to the sixth cervical; but the difference was so slight that even numbering the cells approaches perilously near failure in discovering any sympathy with the muscular defect present in life.

The eighth segment, however, in the left dorso-lateral group revealed a great change in the cells, even none, or one or two being present, while the corresponding right horn had twelve or more well-developed cells. This experience is only common with many others in such investigations that such groups in the lateral cells of the eighth segment are distinctly affected. It is also worthy of note that the Weigert preparations revealed nothing different in the reticular structure of all the segments examined either above the fourth or below.

While engaged on the examination of this patient Parhon and Goldstein published in the Neurological "Centralblatt" the theory of the "metamerien" and "spinal motor localisation" which has now become public property. These authors record their experimental resections of the pectoralis major in dogs as well as examinations of men whose pectorales muscles were removed some time before death. In these experiments they found, in the neighbourhood of the upper half of the fifth segment and to the sixth segment, changes in the anterior horns of the cord except in the medial and dorso-lateral groups. So far as it goes this investigation agrees with my own, as these groups were in my own case quite intact. There appears, however, to be a smaller number of cells affected in Parhon and Goldstein's cases than in my own, and those found were at a higher level, which might be affected by the pectoralis in my case being only partially affected and not wholly paralysed. In their case the one side was particularly observed, knowing the affected side, and might thus be prejudiced in the examination.

Whatever may be the value of these investigations, though few, it is important to note the proximity of localisation, and, as I pointed out at the Paris Medical Congress in 1900, it was necessary to note the variation and compare pathology with symptoms to exactly the limit of variation. If we compare the results of Kaiser and Bruce, who give the particular segment, we are instantly surprised with the extremes of variation.

Flechsig's examinations of the pyramidal paths are equally far apart in a large number of cases. It is possible that the finer structure may be rigidly approximate in the pathology, and from its narrow limit be radiated and the radiation only observed; or, as it is well known that the finer structure of both sides of the cord vary, even in health this congenital condition may be noted as the pathological change in preconceived observers. As an example to illustrate my meaning, I shall give you a sketch of the cord in one of the sections in my own case, taken through the sixth cervical segment, which I shall label B. Alongside of this I give you another sketch from a suicide, taken through the same segment at the same level, and whose muscles were perfectly healthy and strong at the time he perpetrated the deed, which I label A. The cells are marked by dark points, which will be observed to be less in the healthy muscle patient than in the man with the life-standing muscular defect. From the specimens given, the healthy muscular man has the most morbid appearance, and would be accepted as such were the facts not opposed to this assumption. The constant "degeneration" met with in the triangular mark of cervical parts of the cord is nothing more than variations in a healthy state as proved by recent inquiry. These physiological changes have also been proved in the posterior roots by Redlich. The glia in the periphery of the cord, as well as the septum in the posterior commissure, are so anatomically different in healthy individual cases that no correct standard of comparison can yet be fixed for a normal example to be fixed as unity. Although no functional defect can be observed in these variable cases it is quite possible that the anatomical differences may be pathological, or probably better expressed as pathogenic or predisposing changes. I have already pointed out in a former article that comparative anatomy may yet prove that the resistance to disease in the spinal cord is chiefly due to an altered anatomical constitution or construction of the units in the cord. This is no novel theory, as we are now acquainted and frequently assign many other diseases to a pathological "habitus" which it could be no more absurd to speak of a "glieous habitus" of the spinal organ when a glia hypertrophy is found in disseminated sclerosis, syringomyelia, &c.

From these references we may conclude that congenital muscular defects in the spinal cord cannot be accurately defined owing to the wide variation in the anatomically healthy individual closely resembling the pathological conditions.

DOUBLE PYOSALPINX
OF
SEVENTEEN YEARS' STANDING:
WITH SPECIMEN. (a)

By ROBERT HUGH HODGSON, M.D., &c.

THE symptom pain enters so largely into the many diseases to which the generative organs of women are liable and into the different phases of those diseases that it is one of the most misleading of the chaos of symptoms attributable to diseases of the pelvic organs. If, therefore, I attempt in a few words to clear the atmosphere to but a slight degree I trust that you will not consider my effort a waste of your valuable time. Pain in the uterus may be referred to the front over the pubes or behind to the sacrum. When over the pubes the pain is mostly due to interference with the function of the nerves by pressure of blood, as in the approach of menstruation, to the check to that flow by catarrh, to shock immediately preceding the flow causing congestion in the capillaries, to over stimulation by excessive coitus, to alcoholism, to anæmia, or to the pressure of an over-loaded bowel preventing the return of blood. Among the more permanent causes may be enumerated the stimulation of ovarian disease, and the interference with the return of blood from pressure of tumours, from inflammations involving the veins or lymphatics, and from cardiac disease. In an endeavour to name all the causes of congestion of the uterus one might spend an enormous length of time, serve no good purpose, and then be found to have omitted some considered to be most important.

The above list is, I think, sufficiently varied. Pain in the sacrum, one of the commonest indications of uterine disease, is generally considered to be due to direct pressure upon the sacral plexus as by pregnancy, by fibroids or other growths, or by the binding down by adhesions following inflammation, but I venture to express the opinion that pain in the sacrum from this cause is rare in comparison with that arising from pressure upon the nerve terminal filaments of the uterus by causes such as I have specified as giving rise to pain over the pubes. For the most part when the pain is in the front, especially in its early stage, it is functional and amenable to medical treatment, whereas when it is in the sacrum it is the result of long-continued congestion, having wrought structural change in the uterus which necessitates more radical means for its cure. Though it is true that temporary relief can be afforded in a large proportion of these cases by a copious depletion, instances of such must be common to most of us where patients suffering for many years from constant backache seek relief for the day in order that they may be equal to attend a social gathering. Yet it is seldom that such simple tactics suffice to restore the patient to health, for it is in these chronic cases that we may expect to find a large amount of fibrous tissue either interspersed between the muscular structure of the uterus or supplanting it, and by its contracting nature, in addition to its weight, tending to flex the organ upon itself. It is somewhat difficult to conceive that a healthy uterus should of its own accord fall over one way or the other, or that it should, when so displaced by outside influence, remain as an inert body void of the power of self-rectification. Evidence of this loss of power may in some cases be demonstrated by the introduction of a Hodges' pessary, when it will be observed that though the cervix has been thereby canted in the opposite direction the kink in the cervical canal remains. Draw upon the cervix of a flexed uterus with a volsella and the flexion is more or less removed; release the cervix and the flexion immediately returns. The fact that a pessary does, in some cases of old sacral pain, give relief, indicates the degree of mischief wrought in the uterus rather than the source of the pain. The pyriform shape of the uterus, the direction of the fibres of the three layers composing its muscular coat, and the absence of a fixed point in the pelvis, indicate to my mind that nature intended that the uterus should possess exceptional power of retaining its normal shape when non-pregnant, and of regaining it after delivery, and that the majority of flexions are due to pathological changes in the uterus itself brought about by congestion of that organ, and that the relief from pain which depletion gives is due to the reduction of blood pressure permitting the lymphatics to exercise their characteristic activity when relieved of even but a small amount of pressure. I think it will be admitted that the uterus is more often retroflexed than anteflexed, and although there is in the present day a feeling of doubt whether there is such a displacement as anteflexion, still when we find the axis of the body of the uterus almost at right angles to the axis of its cervix, with the acute angle forwards, I think we must say that the uterus is anteflexed. Whether the body be flexed upon the cervix or the cervix upon the body matters not, for we have found that one part is flexed upon the other anteriorly. The explanation of retroflexion being more common than anteflexion may be found in the fact that the posterior surface of the body of the uterus is larger and thicker than the anterior, and therefore, receiving more blood during congestion, affords more encouragement for increased growth of fibrous tissue with its subsequent contraction.

(a) Paper read before the British Gynæcological Society, July 10th, 1902.

The case which I will now, with your permission lay before you, illustrates in several particulars the views I have above expressed.

In the year 1885, a lady, then æt. 19, consulted me for pain over the pubes which became greatly exaggerated with the approach of each monthly period, causing her to roll upon her bed in agony for many hours, and which was accompanied by hysteria of a distressing character. I treated her medically for a few weeks, but without giving much relief. I then examined her and advised hot douches and depletion. This advice had, however, the effect of frightening her, and she sought the assistance of a gentleman in Harley Street, who told her that she had nothing the matter with her beyond hysteria, and gave her a prescription. She did not receive much benefit from his treatment, and struggled on, suffering "dreadful pains in front" at her periods until 1889, when, still believing in the infallibility of her doctor, and being desirous of going to Burmah on mission work, she left this country on the doctor's assurance that she would recover. On the voyage out, however, she suffered intensely with menstrual pains, with a high temperature for a few days. Two months later she was again attacked in the same way. In November, 1890, she was stabbed in the chest by a black. The fright thus given she considered started a pain in her back. She was examined, and a pessary inserted which relieved her back, but as the doctor considered that there was some further mischief than displacement he sent her to the Dufferin Hospital, Rangoon, where she remained under treatment for a month. The treatment consisted in syringing and electricity, which so far relieved the pain in her back that she was able to continue her duties, except during her periods, for four years. In 1894 she had malarial fever with boils all over her body. The pain in her back returned, and a muddy discharge from her vagina commenced and lasted continuously until she came to England in 1896, when she became an out-patient of the Samaritan Hospital for a period of five months, when she was taken in and operated upon. This treatment stopped the muddy discharge and relieved the pain over the pubes for one year, but it did not relieve the sacral pain. In 1897 she returned to Burmah, but had a bad voyage, with return of her old menstrual pains. On arrival in Burmah she was seized with very severe pain in her back, and could walk only with difficulty. Four months later she again had malarial fever, followed by severe pains in her stomach, thighs and legs, with constant fainting, which lasted four or five days. In 1898 two large abscesses formed in her armpits, and in the same year she had a severe attack of pain in her left side, thigh and leg, which was ascribed to inflammation of her womb. From this date her menstrual flow gradually decreased until the present year, when it almost ceased. In 1898, in addition to the pain in her back, which had been continuous since 1896, a swelling, accompanied with pain, commenced in her right side. In 1899 she was sent to Rangoon General Hospital to be curetted, but dilatation of the cervix only was done. The pain in the right side continued until the following December, when the patient was too ill to move in bed. She was given a hot bath for half an hour, when she fainted. She was then syringed daily, and two glycerine plugs inserted. But the pain becoming so extreme, in desperation she took some pennyroyal, after which a cyst burst in her inside, flooding her with a brownish watery discharge, and giving great relief from pain and loss of the swelling in her right side. From that time the pain in her right side, which had lasted about a year, left her entirely. After January, 1900, her menstruation became very irregular, and in November of that year she had an attack of inflammation of her right leg which confined her to bed for a month. From January 1901, until June of this year she had constant headache, diarrhœa and pain.

From the foregoing history, which I am sorry is not more accurately recorded, I think no one will doubt the patient when she says that the seventeen years of suffering she endured had made her life not worth living. Consequently, she again returned to England and placed herself under my care. On May 24th, a few days after arrival, she was put under an anæsthetic and examined, but all that I could find was an anteflexed uterus, and what appeared to be the edges of cirrhotic ovaries. On June 4th she was again put under an anæsthetic, and I opened the abdomen a little to the right of the median line and a little lower than midway between the umbilicus and pubes. There were no adhesions and no trace of an old sac; the uterus was freely movable, cylindrical and anteflexed; the ovarian ligaments were short, and the Fallopian tubes, which were also rather shorter than usual, were about normal in circumference, with retracted fimbriæ and slightly uneven surfaces. The greatest amount of distension of either tube is seen in the specimen now shown. The ovaries are rather atrophied, hard at their free borders and have a degenerated feel at their middle and upper third. I removed both ovaries and Fallopian tubes near to the uterus and closed the abdominal wound, the walls of which were thin, with silk-worm gut passed through the whole thickness. The day following the operation, and for nearly four days after, there was a sanguineous discharge from the vagina small in quantity. On the second day after the operation the pain, which had been incessant in the sacrum for the last six years, disappeared and has not since returned. The pain over the pubes has also subsided. Fourteen days after the operation the patient was up and about her room, and during the following week she took daily walks out of doors. Her temperature never rose above 99·4°. She is now thoroughly restored to health, and intends shortly returning to Burmah to again take up her mission work. Upon subsequent examination of the Fallopian tubes both ends were found closed, and upon slitting them up sacculations were seen containing what appeared to be pus, which, having been examined by the Clinical Research Association, was reported to be "pus with a trace of blood and a very large number of bacilli." A further report said that "the only organism identified was the bacillus fluorescens liquifaciens, which belongs to the group of non-pathogenic bacteria."

In this case the pain over the pubes was constant during seventeen years, with the exception of one year, and the pain was apparently in the situation of the nerve pressure. The sacral pain was constant for six years, and was of reflex origin. The cylindrical shape, the hard consistency, and the return to its flexed condition after straightening point in my opinion to an abnormal amount of fibrous connective tissue. I attribute the relief of sacral pain two days after the operation to lessening of the blood supply to the fundus and the subsequent absorption of arterial blood exudation. The ovarian monthly stimulation of the uterus to congestion having been checked, there will be no need for development of collateral circulation, whilst absorption having been thereby stimulated, I trust that there will be no return of pain.

ASTHENOPIA. (a)

By E. KENNETH CAMPBELL, M.B.Ed., F.R.C.S.Eng.,

Surgeon to the Western Ophthalmic Hospital; Surgeon-Oculist to His Highness the Maharajah of Baroda.

(Continued from page 102)

Orthophoria, or Ocular Equilibrium.—This term has reference to that condition of sight in which the two eyes work in perfect unison, whether in a state of repose, and during fixation: in plain words, when they act alike. The following experiment will illustrate the meaning of this: Let a person be required to fix an object two feet off, and a card be made to screen one eye, it can be seen that this covered eye, although now excluded from vision, still retains its position of correct fixation and does not deviate. This associated, or conjugate, action of the two eyes implies *perfect muscular balance* or *orthophoria* (Gr., orthos — right, phoreo — I bear), and is the outcome of the co-ordinate actions of various groups of muscles, controlled by a centre in the brain. Any disturbance of the proper working of this neuro-muscular machinery causes want of balance, technically known as *insufficiency* or *heterophoria.* Orthophoria, then, means proper muscle-balance, with no tendency to deviation, while heterophoria signifies a tendency to deviation which requires an effort of will to control.

Asthenopia (asthenès — weak, ops — sight), as before explained, is a condition in which visual acuteness remaining good, even though all refractive error may have been corrected, there is still an incapacity for sustained visual effort.

The symptoms associated with it are various, and may be briefly summarised as: An inability to read or work for any length of time without "eye-strain," the eyes becoming hot, uncomfortable, heavy, or beginning to ache; headache either referred to the brows or the head generally; conjunctival irritation, photophobia, blepharitis, neuralgia, tenderness on pressing the globes, a feeling of tension or heaviness in the eyes, and occasionally diplopia, giddiness and nausea. Sometimes a patient may complain of the eyes feeling "like balls of fire."

All these symptoms are liable to become specially marked towards the end of the day, and may be particularly noticeable when working in artificial light.

A not uncommon cause is the wearing of wrong glasses, more especially such as are incorrectly centred with respect to the pupils, in consequence of badly-fitting frames. A de-centred lens in front of one eye for instance, acts as a prism and means a displacement of the retinal image, necessitating an effort of squinting proportinate to the displacement in order to effect binocular single vision.

Causes.—(1) General.
(2) Local.
Both of which often co-operate.

(1) *General.*—Any debilitated state of the system inducing premature exhaustion of the neuro-muscular apparatus of the eye, *e.g.*, influenza, recovery from an illness, childbirth, the various forms of anæmia.

Local.—*(a)* Accommodative.
(b) Muscular.
(c) Nervous.

(*a*) *Accommodative.*—This is, perhaps, the commonest form, and is not to be confounded with the natural fatigue of the ciliary muscle through excessive use of the eyes.

It may be met with in any refractive condition, but is especially apt to occur in astigmatism and anisometropia; in both these cases because the patient tries to correct the refractive error by unequal contraction of the ciliary muscles.

It is particularly liable to develop after influenza, childbirth and recovery from an illness.

Symptoms.—The images of print and of all near objects become blurred, as the exhausted ciliary muscle relaxes and cannot maintain a state of sustained contraction; pain in the eyes and forehead; headache. At first these symptoms may be noticed only towards the end of the day, but after a time they often become chronic.

(*b*) *Muscular.*—This form of asthenopia is generally known as *muscular insufficiency* or *heterophoria,* and is due to a weakness of the extra-ocular muscles, more especially of those concerned in convergence,

---

(*a*) *Gr.* asthenes—weak, ops - sight.

the internal recti, and hence is most frequently found in connection with *myopia*, though it may occur in emmetropia, hypermetropia, or astigmatism. In this variety of asthenopia there is a *latent tendency on the part of one eye to deviate from its fellow*, and so cause diplopia. This constant tendency to deviation *can only be overcome by a forced muscular effort*, the result of increased innervation, *i.e.*, in excess of that normally required. It is accordingly *a condition of forced equilibrium*, and so is on the borderland of squint, and was called in consequence *latent squint* by von Graefe. (In real squint the deviation of the axis of the eye cannot be overcome by a forced muscular effort.)

Varieties of Heterophoria.

Taking as our standard perfect muscle-balance, orthophoria, we have:—

(i) Exophoria — a tendency to outward deviation.
(ii) Esophoria — a tendency to inward deviation.
(iii) Hyperphoria — a tendency to upward deviation.
(iv) Hypophoria — a tendency to downward deviation.
(v) Hyperexophoria — (i) + (iii).
(vi) Hyperesophoria — (ii) + (iii).

As a very rare clinical condition *cyclophoria* or "rotatory" heterophoria may be found. It is usually met with in astigmatism when the principal axes are oblique.

Muscular asthenopia may occur with any form of ametropia, and even emmetropia, but when of purely local origin is generally associated with myopia or hypermetropia; for in both of these conditions there is a lack of the natural harmony between accommodation and convergence, the myope being called upon for an effort of convergence in excess of accommodation, and the hypermetrope for an effort of accommodation in excess of convergence.

Symptoms.—The eyes soon become fatigued, and ache. There are often vague sensations of discomfort referred to the eyes and head generally, and there may be indefinite feelings of languor and disinclination for prolonged mental exertion, especially writing. There may also be complaint of diplopia and vertigo, and both the conjunctiva and margin of the eyelids may look reddened. If one eye be closed the symptoms of asthenopia disappear, as now convergence is no longer necessary for fixation.

Tests for Muscular Insufficiency.

(*a*) *Fixation Test.*—The normal convergence-near-point is two inches, approximately corresponding to tip of nose. Let the two eyes steadily fix an object (*e.g.*, uplifted finger or a pencil, &c.) held in the horizontal median plane thirteen inches off. Now bring the object gradually closer to the face, when it will be noticed that one eye becomes unsteady in its fixation, and after a short period of oscillation, either slowly or suddenly, deviates outwards (exophoria) *before the normal convergence near-point is reached.*

(*b*) *Screen Test.*—Whilst the patient is still fixing the object, cover one eye and then the other alternately with a screen, and assume that there is deviation of the covered eye outwards. Suddenly withdraw the screen, diplopia ensues, as the visual axis of this eye is directed outwards. To obviate the double-vision a forcible effort will be made by the deviating eye to turn inwards in order to fix the object and so effect binocular single vision.

This muscular insufficiency requiring a forcible effort to redress the disturbance of equilibrium is sometimes known as "latent squint," as before explained.

(*c*) The normal balance, sufficiency, or fusion power, of the extra-ocular muscles is expressed by the strength of the prism that each muscle by forcible effort can overcome in order to fuse the resulting double images. It is determined in the following way:—Take the patient into the dark room and place in front of him a small flame six metres off, and on the same horizontal level with the eyes.

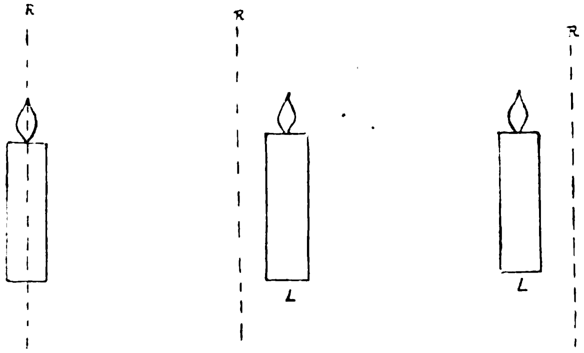
Convergence.—Beginning with a weak one, place stronger prisms in turn before one eye, each with its base towards the temple. The strongest with which the flame remains single gives the measure of the power of internal recti. In a similar way test the power of the external recti by placing the prism with its base towards the nose, and then the superior and inferior recti by placing the prisms with their bases respectively downwards and upwards.

The internal recti being the strongest (they have an insertion into the globe further forward than the others) of the extra-ocular muscles, because so much used for convergence, have a fusion-power, *i.e.*, can overcome

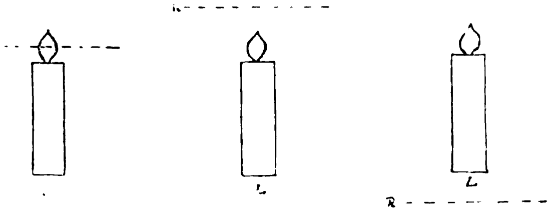
a prism of	30° to 50°
external recti	6° to 8°
superior and inferior recti	3°, but may be higher.

If diplopia results from the employment of prisms of the above-indicated powers, the case is one of muscular insufficiency.

The Maddox Rod-Test in:



Orthophoria. Exophoria. Esophoria.



Orthophoria. Left Hyperphoria. Right Hyperphoria.

(*d*) One of the most accurate and delicate tests for muscular insufficiency is by means of the *maddox-multiple-rods*. This is a contrivance by means of which the image of a flame as seen by one eye is converted *into a long streak of light that is at right angles to the axis of the rods*, which, being so dissimilar in appearance to the flame itself, has no tendency to be fused into the image formed by the other eye. It is generally made of red glass so as to make the contrast the more marked.

Method of Application.—Both eyes are kept open and uncovered, and the patient is directed to look at a flame six metres off on the same plane with the eyes, and the cylindrical bars are to be placed in front of one eye *horizontally*. If the muscular balance be correct (orthophoria) a red streak of light will be noticed situated vertically, and corresponding to the long axis of the flame as seen with the other eye.

If the red-streak be displaced laterally there is muscular insufficiency, *e.g.*, if the red streak appears to the left of the flame—crossed diplopia; if to the right—homonymous diplopia.

The amount of insufficiency is measured by the prism, which, held in front of the maddox-rods, will cause the red streak of light to correspond exactly to the long axis of the flame.

For testing the power of the superior and inferior recti the rods should be placed vertically, when the image of the flame will be converted into a horizontal streak of light, which should cut the flame at right angles. The degree is measured by prisms in the same way.

Rules for Correction by Prisms.—Find the sum of the correction for *both* eyes. If the insufficiency be less than 16°, take one-fourth as the maximum correction for each eye. This should rarely exceed a prism of 4°, under any circumstances, on account of the weight and chromatic dispersion a stronger prism entails. *Begin by prescribing half of this*, and increase the strength according to results.

Examples.—R. E. with maddox-rods placed horizontally the patient sees the red-streak 9° to the right and with L. E. 7° in the left

$9^\circ + 7^\circ = 16^\circ =$ total amount in the two eyes together.

$16^\circ \div 4^\circ = 4^\circ$

prescribe prisms of 2° with their bases out for each eye, and change to stronger (not exceeding 4°) if found desirable.

Prisms are to be regarded as affording merely a temporary relief, and are not for permanent use. It is to be understood that they do not remove the cause of the deviation, they simply *relieve* the discomfort. It is only when other means fail that they are to be employed, and under no circumstances should they be used for too long a time on account of the fact *that their prolonged use is liable to cause an increase in the insufficiency*. If spherical glasses are worn, de-centred lenses are to be preferred.

In exophoria the base of the prism must be turned *in*.
In esophoria the base of prism out.
In hyperphoria up or down.

(*c*) *Nervous.*—Other names for this are: *neurasthenic*, and *hysterical*, asthenopia. It must not be confounded with simulated blindness.

In all cases of the affection it is assumed that the visual power is good; and that if ametropia exist, the suitable correction has been supplied.

It is *to be regarded as a neurosis*, and most cases are to be found among hysterical young women.

The symptoms are those arising in connection with a complicated neurosis in which the visual phenomena play merely a part.

Diagnosis.—Alterations in the visual field, such as peripheral contraction, hemiopia, scotomata, rapid blurring or the complete blotting out from view of the object fixed; photophobia; pains in the eyes or head, so that the work has to be laid aside. The subjects are usually women suffering from anæmia, uterine disorder, or those convalescent from an acute disease. Although the symptoms may last a long time, even years, the prognosis is distinctly good.

Treatment of Asthenopia.

The general health is to be attended to. *Any ametropia that may be present is to be properly corrected*, and all near objects are to be held as far off as possible compatible with clearness of definition. If continuous near work be rendered difficult, owing to weakness of the internal recti, prisms or de-centred lenses must be worn.

De-centration of Lenses.

If ordinary lenses are necessary, but the action of a prism is required as well, the effect of a prism can be produced by de-centring, *i.e.*, grinding the lens in such a way that the geometrical centre falls upon an excentric part.

For example, if a convex spherical glass be de-centred *in*, or a concave spherical lens be de-centred *out*, the effect is that of a prism with its base *in*.

So, likewise, if a convex lens be de-centred *up*, or a concave lens be de-centred *down*, the effect is that of a prism with its base *up*.

Rules for Correction by De-centred Lenses.—A spherical lens of 1D in order to produce the effect of a prism of 1° must be de-centred at 8·7 mm. Accordingly, knowing the value of the prism necessary, we multiply it by 8·7, and divide the result by the strength of the spherical lens required.

E.g., a 6D spherical lens combined with a prism of

$$2^\circ, \text{ base } in = \frac{2 \times 8{\cdot}7}{6} = 2{\cdot}9 \text{ mm.}$$

hence in this case, the 6D lens, in order to possess the added value of a 2° prism, must be de-centred 2·9 mm. inward.

If, in spite of the adoption of the above-mentioned methods of treatment, symptoms of asthenopia still persist, the eyes should be given a long rest by abandoning all forms of near work, *and protecting them from light by the use of tinted glasses*, and, in the case of young subjects a prolonged course of atropine instillation is often necessary.

In the nervous, or neurasthenic form, hypodermic injections of strychnine and the employment of the constant current will often bring about an excellent result.

The application of the constant current to the cervical sympathetic more particularly is to be recommended.

Tenotomy.—If other methods fail, tenotomy is sometimes of considerable value in well-selected cases.

Summary of Treatment.—In the *accommodative* and *heterophoric* varieties of asthenopia, undoubtedly the most promising method of treatment is *to accurately correct the error of refraction*, if present. ·25° of astigmatism, left uncorrected, may make all the difference between success and failure. Let it be clearly understood *that the more accurate the correction, the greater the improvement*. I never hesitate to order presbyopic glasses from the age of thirty years, or even earlier, for those who have to do much reading or writing.

If glasses are unsuccessful in giving relief, completely rest the eyes for a given period, and endeavour to improve the general health. If after this the symptoms still persist, prisms, in addition to the glasses or de-centred lenses, should be given a trial. Lastly, if all these means fail, tenotomy must be resorted to.

A METHOD OF TREATMENT OF CERTAIN CASES OF EMPYEMA.

By WILLIAM TURNER, M.S., F.R.C.S.,

Senior Assistant Surgeon, Westminster Hospital; Surgeon, Royal Hospital for Diseases of the Chest, City Road; Surgeon, Seamen's Hospital Society, Dreadnought Hospital, Greenwich.

AMONG the patients suffering from empyema that the surgeon is called upon to treat, there are a certain number to whom the administration of a general anæsthetic is attended with great danger. The cause of this is probably two-fold: first, the direct mechanical action of the presence of a large collection of fluid in the pleural cavity disturbing the action of the heart, and secondly, the altered condition of the heart muscle due to the absorption of toxins, partly from the empyema and partly from those connected with the illness which precedes and causes the empyema.

Many deaths have been reported during the administration of chloroform to patients suffering from an empyema. In all text-books special stress is laid on this fact. Death is due, probably, not so much to respiratory as to cardiac failure, as mentioned above; this was certainly so in a case under my care, on whom an operation was about to be performed for the relief of a large empyema on the left side, which had been present between four and five weeks; chloroform was administered by the open method, but before one drachm had been given the heart stopped beating, and although everything was done it did not respond to treatment.

Unfortunately, gas and ether are not suitable drugs for these cases, as the congestion produced by their administration makes them dangerous indeed; and chloroform or A.C.E. mixture must be chosen, and it should not be forgotten that both these are circulatory depressants.

In cases where it is certain that the risk of a general anæsthetic is very great, I find it very useful to drain the cavity for a time by means of a cannula introduced through an intercostal space by means of a trocar, under local anæsthesia only. This obviates for a time the necessity of a general anæsthetic, and saves the patient from running extra risk thereby; though the further treatment of the condition by excision of a portion of a rib, and so obtaining free drainage and exploration of the cavity must, in most cases, be resorted to later, especially in those in which there is a large amount of lymph lining the walls of the cavity; but then the danger of the anæsthetic is much less, as the two main causes of danger are removed.

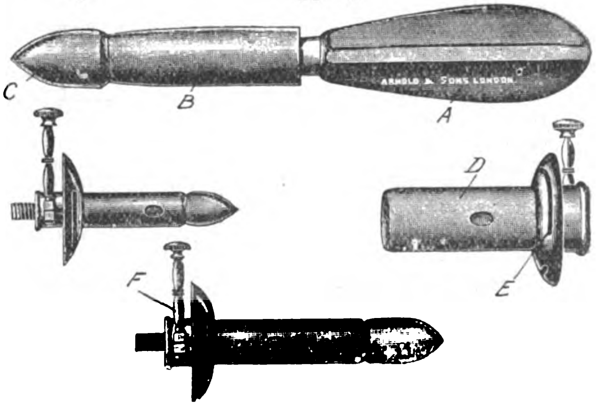
The method of procedure is as follows:—

The whole of the skin of the side affected is thoroughly purified, and rigid antiseptic precautions are observed throughout. The spot for insertion of the trocar is then chosen; if possible, the seventh space on the right side, and the eighth on the left; in the posterior axillary line, or just in front of the anterior margin of the latissimus dorsi muscle. A 4 per cent. solution of eucaine β is then injected subcutaneously, superficially and deeply, over an area of a circle of two inches radius from the spot chosen. An exploring needle is then introduced into the pleural cavity to confirm the presence of pus in this situation, and the proximity of the lung to the chest wall noted by the point of the needle. The needle having demonstrated the presence of pus, the lung being sufficiently far removed from the parietal pleura, and the part being sufficiently anæsthetic; an incision an inch and a-half long is made through the skin, with a scalpel, parallel to the margin of the rib, and gradually deepened until the external intercostal muscle is exposed covering in the space. The specially made trocar and cannula is then suddenly and deliberately plunged through the muscle into the cavity, the trocar withdrawn, and the cannula left *in situ* draining off the pus. The cannula is then fixed by means of tape round the chest, the orifice covered by a large piece of purified protective, and this again by a large antiseptic dressing, held in position by a many-tailed bandage.

The protective over the tube serves to act as a valve, allowing the pus to pass through the tube, but preventing air from entering with each inspiration, thus assisting the lung to expand. The dressing is changed as often as necessary, with strict antiseptic precautions, the protective being left *in situ*. The silver cannula is replaced by an indiarubber tube after the second day, and later on if necessary, some further operation undertaken for the cure of the case.

The special features of the instrument are seen in the accompanying diagram.

The cannula, and, of course, the trocar to fit it, is oval in transverse section and not round, to enable it to be more effectively used between the ribs, the long diameter in the long axis of the intercostal space; the cutting edge of the trocar is in the same diameter so as to prevent any risk of wounding the intercostal vessels or nerves. To allow for this long razor edge the head of the trocar is comparatively very large, and in the full-sized tube projects nearly three-quarters of an inch from the end of the cannula. In using the trocar there is therefore a certain amount of risk of wounding the lung, but this is provided against in two ways—first, by noting the distance of the lung with the exploring needle, as mentioned above, and, secondly, by adjusting the movable shield on the cannula, which can thus be used to prevent the trocar from penetrating too deeply. The shield is fastened to the cannula in the same manner as the shield of a Durham's tracheotomy tube, and the top of the cannula is fitted with a rim to prevent the shield slipping off.



A. Handle fitted with screw to fit trocars of all sizes. *B.* Trocar. *C.* Large head of trocar with cutting edge. *D.* Cannula. *E.* Shield with slots for tape. *F.* Adjustable screw for fixing shield on cannula.

In the shield there are two slots, so made that whatever the position of the tube (*i.e.*, whatever the direction of the ribs), pieces of tape threaded through them will pass horizontally round the chest and keep the tube in place. The cannula has two small openings near to its inner end on the upper and lower surface to allow for better drainage.

Below will be found notes of some cases in which this method of treatment has been adopted.

1. C. S., æt. 28, a sailor, developed acute basal pneumonia on the left side during the fourth week of a severe attack of enteric fever, and this was followed by a large empyema on the same side. The temperature was of the hectic type, the whole of the left lung out of action, and signs of fluid extended up to the third rib in front. The heart sounds were almost inaudible, the apex beat could not be made out; the pulse was very feeble and rapid; there was much dyspnœa, and he was unable to lie on either side.

A general anæsthetic was considered extremely dangerous, so a trocar and cannula was inserted in the manner described above in the eighth space as far back in the axilla as it was possible to get, as the patient could not be turned over at all. The pus was thin and drained away well; no masses of lymph appeared to be present. The tube was removed on the sixth day, and replaced by an indiarubber one of half an inch in diameter. No further operative treatment was found necessary. The cavity gradually closed, and finally healed completely. The pus was found to contain the typhoid bacillus only.

2. E. L., female, æt. 36, was admitted into the Royal Hospital for Diseases of the Chest on November 24th, 1899, suffering from pain in the left side of the chest, and on examination some indefinite physi-

cal signs were found at the apex of the left lung. On December 8th she developed acute pleuro-pneumonia at the left base. Fluid was poured out very rapidly, and this necessitated aspiration on the 15th and 16th, more than two pints of semi-purulent fluid being withdrawn on each occasion. The next day her condition was extremely serious, temperature, 102·4°; respirations, 52, shallow; pulse, 136, very soft and feeble; dyspnœa was marked and face and extremities were cyanosed.

The signs of fluid in the left pleural cavity extended as high as the spine of the scapula; the apex beat of the heart could not be made out, but the area of cardiac dulness extended well over to the right of the sternum.

A general anæsthetic was out of the question, so, aspiration having failed to give relief, it was decided to drain by means of a cannula, which, under eucaine, was introduced through the ninth space in the posterior axillary line, and forty-five measured ounces of pus removed. This was followed by slow but gradual improvement, but on the second day she complained of pain, which radiated from the wound to the middle line in front. The pain seemed to be due to the pressure of the silver tube passing through the intercostal space, so the cannula was removed and replaced by an indiarubber tube, and the pain was relieved. No further operative treatment had to be adopted, and she was discharged well on February 15th, 1900.

The pus contained the streptococcus pyogenes and the diplococcus of pneumonia.

3. A. T., male, æt. 24, was admitted to the Royal Hospital for Diseases of the Chest on July 4th, 1901. For years he had suffered from chronic suppurative diseases of the middle ear on the right side, and five weeks before admission had been operated upon for suppuration in the mastoid cells. A fortnight later he was suddenly seized with acute pain in the right side, followed by a severe attack of pneumonia with pleural effusion. On admission to the hospital he was almost moribund, the temperature was subnormal, the heart was felt feebly beating in the axilla, and the pulse was feeble and irregular. A general anæsthetic was clearly impracticable, so under eucaine a cannula was inserted in the seventh space, and five pints of pus came away. The cannula was changed for an indiarubber tube on the fifth day, and without any further operative treatment the cavity healed up, and he was discharged well on August 29th.

The pus contained the streptococcus pyogenes in pure culture.

4. D. C., a female child, æt. 4, was admitted to the same hospital on February 17th, 1902, three weeks after an acute attack of pneumonia. On admission the temperature was 99°; there was marked dyspnœa; the right side of the chest was completely out of action, and bulging of the intercostal spaces was very noticeable; signs of fluid in the pleura extended up to the clavicle. The heart was found beating feebly and irregularly in the left axilla, the apex beat being in the posterior axillary line. The condition was far from a favourable one for a general anæsthetic, so a cannula was inserted into the eighth space. Rapid improvement followed, but on several occasions the tube was found blocked when the dressings were removed. So on March 3rd, A.C.E. was administered, and two inches of the eighth rib excised, and the pleural cavity opened and explored. Large masses of lymph were found lining the whole cavity; these were removed, and the cavity drained by a short indiarubber tube of three-quarters of an inch diameter. Uninterrupted convalescence followed, and the child was discharged quite well on April 17th.

The pus contained the diplococcus pneumoniæ only.

5. G. S., male, æt. 29, had suffered two years previously from an attack of pneumonia, followed by pleural effusion which at that time had necessitated aspiration many times, but the fluid was in every instance clear.

He was admitted on February 20th, 1902, having been laid up at home for five weeks with cough, pain in the right side, and dyspnœa. The temperature was 103°, and the right side of the chest was found to be full of fluid, the heart pushed over to the left, and his general condition extremely bad. An exploring needle revealed pus, and not clear fluid as was hoped; but as his condition was urgent, three pints were removed by aspiration. The relief obtained by this means was so slight that on the next day, his condition being most unfavourable for a general anæsthetic, a cannula was introduced and five pints of foul-smelling pus removed. The tube worked out on the second day and was replaced, but as this complication occurred again owing to the patient being troubled with severe cough, A.C.E. was given three days later, and three inches of rib removed and the cavity well drained,

The discharge was most profuse; the lung showed no tendency to expand, and he left the hospital *in statu quo.*

The pus contained tubercle bacilli and all kinds of septic micro-organisms, including the bacillus coli communis.

These cases illustrate the utility of this method of treatment of urgent cases of empyema. In three of them this slight operation without a general anæsthetic was sufficient to bring about the complete cure of the case. I cannot, however, and I do not wish to, claim for this method of treatment that it will be found sufficient to cure even most cases of empyema, as by far the greater number are caused by the pneumococcus, and are accompanied by a great quantity of lymph lining the walls of the abscess, and this must be removed before a cure can be hoped for (case No. 4 is a typical example of this).

But this method of treatment is of great use as a *temporary measure* in those cases in which the administration of a general anæsthetic is obviously attended with great risk. It has been shown over and over again that aspiration does not give relief in the same manner; this is well illustrated in case No. 2.

I do not think that the cannula method is suitable in tuberculous cases, as I am sure that if possible aspiration only should be resorted to, unless, as in case No. 5, the presence of septic micro-organisms make it imperative to drain the abscess, but even then it is only temporarily useful.

Occasionally there is some difficulty in keeping the tube in position owing to the restlessness of the patient or to continual coughing; this occurred in case No. 5, coughing being incessant both before and after the operation. By inserting an elastic accummulator into the tape going round the chest this complication can in most cases, I think, be avoided.

Another disadvantage to the cannula sometimes met with is the pain produced by its presence in the intercostal space, causing some pressure on the nerves, this occurred in case No. 2. This may determine the changing of the cannula for an indiarubber tube earlier than usual.

Provided that the hypodermic injection of eucaine is thorough, the introduction of the trocar and cannula produces practically no pain, but only a momentary start and catch in the breath, and so does not preclude its use in young people.

Clinical Records.

COMPLETE REMOVAL OF URINARY BLADDER.

By A. W. Mayo Robson, F.R.C.S.,
Vice-President, Royal College of Surgeons of England.

At the Manchester meeting on July 31st, Mr. Mayo Robson described a case of complete removal of the urinary bladder in a female patient, æt. 44. The operation had been performed for universal papilloma, which had been removed by supra-pubic and urethral operations on six occasions during the previous two years, but which had recurred rapidly, and was at this time causing serious loss of blood and forming a tumour reaching within three fingers' breadth of the umbilicus. The operation had been performed in the Trendelenberg position, and it was found comparatively easy to enucleate the bladder from beneath the peritoneal envelope, ligaturing the vessels as they were divided until the ureters were reached, when they were divided and transplanted into the vagina without difficulty. The urethra, which was free, was then ligatured *en masse*, and the whole bladder removed. The urine from the ureters on being collected, showed that the left kidney was already infected, and that the urine from it was scanty, purulent, and offensive, but the urine from the right kidney was fair in amount and quite healthy. For the first week the patient progressed satisfactorily, but uræmic symptoms developed in the second week, and the patient died in a state of coma on the thirteenth day.

Mr. Robson believed that this was the first case in which the entire urinary bladder had been removed in this country, and from his experience in this operation he felt that it was much more feasible than had been hitherto supposed, for the whole operation only occupied a few minutes over the hour. Had it not been for the untoward event of nephritis having already developed before operation in the left kidney, he thought that the operation would have been a complete success.

It was quite clear that nothing short of complete removal offered the patient any chance of cure, and the specimen which he was able to show to the meeting would, he thought, convince everyone that removal of the growth could only have been completely effected by taking away the entire bladder.

CASE OF ALMOST COMPLETE GASTRECTOMY.

Mr. Mayo Robson also described a case in which eighteen months ago he removed a tumour weighing one pound, and involving nearly the whole of the stomach, from a man, æt. 38, the patient having made a complete recovery and being at the present time of normal weight and in good health. The growth removed was either sarcoma or soft cancer, but unfortunately it had been lost by the porter of a pathological laboratory where it was sent for preparation and report. He described the details of the operation, which involved the removal of the entire stomach including the pylorus, the only part left being a small portion of the dome adjoining the œsophagus on the left side; this, he thought, was an important detail of the operation, for it simplified the technique and enabled a junction to be effected between the duodenum and the cardiac orifice of the stomach, the duodenum being joined to the end of the œsophagus on the right, and on the left to the small remnant of the dome of the stomach, one of the author's bone bobbins being used as a splint over which to apply two continuous sutures. The whole procedure involved only a few minutes over the hour.

Mr. Robson referred to other cases in which he had done radical removals of cancer of the stomach with signal success, immediate and remote, and he insisted on the importance of an early diagnosis and an early exploratory operation, so that such cases might be caught in time for a radical operation to be effectually performed.

Steps are being taken to arrange for a World's Congress of Tuberculosis in St. Louis, U.S.A., in 1904. So much for the Americanisation of the study of tubercle.

France.

[From our own Correspondent.]

Paris, August 10th, 1902.

Appendicitis.

At the meeting of the Académie des Sciences, M. Lannelongue spoke on appendicitis and its causes. He said before the true nature of the affection was known it was generally considered as acute peritonitis. In order to verify this assertion he obtained a list of all the cases of non-tuberculous peritonitis treated at the Hôpital Trousseau during a period of five years commencing in 1885, and also the cases of appendicitis for a similar period from 1895 to 1899, and found the number of cases were very nearly the same. For the former 470 cases were recorded, and for the latter 490.

As to the causes of the affection, they were evidently due to the bacterian flora of the appendix. A certain value should be attributed, however, to the nature of the organ (closed vessel theory), and also to the eating of too much meat. The *role* played by worms as demonstrated by Metchinkoff appeared to the speaker beyond doubt, for those parasites loaded themselves with microbes, wound the intestine and frequently penetrate the appendix.

Ectopia of the Testicle.

M. Mignon communicated three cases of ectopia of the testicle which he treated successfully by resection all the vessels of the spermatic cord, except the vas deferens. It had been thought that section of the spermatic artery would provoke atrophy of the gland, but such did not occur in his cases.

M. Lucas said that as retraction of the cord was due to fibrous tissue developed along the vessels, such favourable results as those mentioned were frequently not permanent. He operated on a case of the same nature, and after a few weeks necrosis of the testicle set in.

M. Kirmisson was of the same opinion as the last-named speaker. He cut the spermatic artery in one of his cases, and the gland atrophied gradually.

Sutured Wounds of the Heart.

Another member related an interesting case of perforating wound of the heart treated with success by suture.

A man with suicidal intent shot himself through the heart. Carried to the hospital in a collapsed condition, he was immediately examined. The heart beats were dull and laboured, presenting evident signs of effusion of blood into the pericardium. A large opening was at once made over the region and the pericardium exposed and slit, giving exit to a considerable quantity of clots. The operator, seizing the heart in his hands, discovered a small wound near the apex, with a corresponding one on the other side, marking the course of the bullet. Both wounds were sutured and a drain placed in the pericardium. Five days afterwards the drain was removed, and the man recovered rapidly.

The French Surgical Congress, 1902.

The Fifteenth Session of the French Surgical Congress will open at Paris on October 20th. Two important subjects have been noted on the programme: (1) The surgery of the heart and of the pericardium. (2) The treatment of tetanus.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 9th, 1902.

IT may be interesting to educationalists to know that the University of Berlin registered for summer session 5,676 students, against 5,101 matriculations for the previous summer session. In the faculty of theology there were 274, of whom 211 belonged to Prussia; law, 1,714, of whom 1,353 were Prussians; medicine, 1,018, but only 632 were Prussians; philosophy, 2,670, of whom 1,925 were Prussians.

For the summer session there were 370 females admitted, against 303 the previous corresponding summer session.

A further analysis showed that among the 1,353 law students educated in Prussia 1,316 came from the Gymnasialabiturienten, leaving only 31 from the Realgymnasium and 6 from the Oberrealschulen.

Of the 632 Prussian medicals 615 came from the Gymnasium and only 17 from the Realgymnasium. It is remarked that the Real-schul-abiturienten are low, though through what cause the critic is silent.

THE ALGEOSCOPE.

Francke, of Munich, has added another term to our diagnostic implements, but we fear it is only in name, although he is earnest in claiming "all rights." Every inflammatory centre, he affirms, is susceptible to pressure—that is, produces pain on local pressure, the chest or lungs being no exception to the rule, as the yielding of the cartilages on the ribs and sternum permits of this pressure being applied to locate pain as easily as it is among the soft structures.

The intercostal spaces are self-evident, and can easily be manipulated, as every practitioner knows, but over the hard structures it is not so clear to locate beyond a general diffuse tenderness. However, he claims no specially manufactured instrument that may be had from this or that "fabric" beyond the points of the fingers and balls of the thumbs. He considers his algeoscope to be of immense importance to the clinician, as no doubt it must, but the painting with iodine and photographing the spot is carrying this utility too far. The pleura, lung, and cardiac, according to his photographic experience, is an easy, certain, and accurate method of diagnosis.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 9th, 1902.

HÆMOMETER.

As the greater number of teachers have left town to air their new ideas at the various medical meetings, we must necessarily follow to have the latest to date. Jolles went to the "Naturforscher" meeting to show his hæmometer, which he has recently improved to comprehend the measurement of phosphorus as well as iron, nuclein, &c. His ferrometer is a modification of Fleischl's more expensive instrument, only graduated between 90 and 100 for immediate convenience. The most important, he said, was the estimation of the phosphorus in the blood, as on its presence depended the condition of the erythrocytes and leucocytes as well as the quantity of protein and nucleol-albumen. Under the non-albuminous substances of the cell the phosphorus is in combination with lecithin, alkalies, and even carbonic acid, which play a very active part in the blood corpuscle; therefore to know the amount of phosphorus in a given quantity of blood will be of more value in clinical diagnosis than a more accurate knowledge of the iron present. Again, the phosphorus of the cell is drawn from the fluid, and will depend on this substance in the serum, which usually contains far less in the morbid condition than the normal, whereby the nutrition suffers and the blood cell rapidly falls into decay. The nearer the hæmatic fluid can be kept to the normal state of phosphorus found in health, the more robust and salutary will the cells be found in the performance of their function.

The principle of his instrument for measuring the phosphorus in the blood depended on the intensity of the yellow colour produced with the molybdate of potassium. The standard colours were of glass attached to the "phosphometer," and can be read off immediately.

QUANTITATIVE ESTIMATION OF FATS IN DIGESTIVE SECRETIONS.

Volhard, at the same meeting, showed how the digestion of fats could be accurately measured at any instant during the process of digestion. Hitherto the results have been so varied that no real value could be put upon them for clinical purposes. This was due to the cholin with which the secretions were mixed allowing the digestive process to proceed when placed in a warm room, as the ferment that breaks the fat up went on manufacturing more than it did in the ordinary process. Volhard places the artificial mixture such as the yellow part of an egg with the gastric secretion for a given time, when he adds 75 cc. of pure ether and shakes well. Allowing it to separate he draws off an aliquot part of the clear fluid, say 50 cc., to which again he adds other 75 cc. of alcohol, and then titrates, which gives a percentage of the fat, broken up in the digestion. By this method he and Slate found that the fat is in regular proportion to the time exposed to the secretion, and confirms Schutz and Borisson's law that the product of digestion is in proportion to the square root of the ferment present.

ALBUMINOID ASSIMILATION IN THE STOMACH.

Glaessner, of Prague, brought forward another subject of equal interest on the retrogression of albumen in the stomach. After a long introduction of literature and example he gave us the result of his experiments on dogs which he fed with meat and then killed, when the mucous membrane of the organ was examined and tested and found to correspond to the stage of digestion. The cases were roughly divided into two classes, viz., examined very soon after feeding, the others between two and three hours. The stomachs that were retained for two or three hours were kept at body heat for digestive purposes. The nitrogen in the coagulable, as well as the non-coagulable substances, was estimated as the process was checked by means of the sulphate of zinc, and thus the difference was the estimated loss of albuminose nitrogen.

In the first case the mucous membrane had the property of a retrograde action of converting the albuminoid digestive product into a non-coagulable but insoluble body which corresponded to the albumose. This transformation commences immediately digestion begins and is continued regularly for eight hours. He cannot perceive any "subferment" which many other authors have observed.

THE BRITISH MEDICAL ASSOCIATION IN MANCHESTER.

REFLECTIONS AND RECOLLECTIONS.

The Manchester meeting of the British Medical Association may well claim a large measure of success, both as regards the number of visitors and the interest of the festivities; but with regard to the scientific work accomplished the gathering can hardly be termed notable. With the recasting of its constitution it will be well if the Association realises the need for a reawakening in matters scientific, and a quickening in professional concerns. Much might be done to renew interest in the essential work of the annual meeting. For long, evidences of decay have been only too apparent. The leading scientific spirits are not attracted to these annual "picnics," faddists and mere enthusiasts loom large, serious discussion of subjects needing careful analysis is oftentimes conspicuous by its absence, papers submitted are frequently of but little interest and no permanent value, and the attendance at many of the sections is deplorably meagre. The time has certainly come when in the interests of professional decency a determined effort should be made to raise the scientific work of the Association into its proper place.

It is perhaps well to consider that the President, like the King, "can do no wrong." Certainly Mr. Walter Whitehead so far has received most loyal support. It must, however, be admitted that his address was of local rather than general interest. If it is to be the President's duty to laud the past and praise the present, as regards the Association centre, many will support the suggestion that such eulogium would find the most fitting place in the Handbook.

Certainly, it is a most difficult thing to select a subject for a presidential address, or matter for occasions where the audience is not only mixed but in an essentially frivolous state of mind. Probably means may be found whereby in the future the presidential address may be restricted to terms of general welcome, the special addresses limited to a strictly professional audience, and greater opportunity given to each president of a section adequately to review the work of the preceding year. By some such reform science would gain much and social functions would be relieved of much tedium. Much praise should be given to all concerned in the organisation and conduct of the recent gathering. In spite of exceptional difficulties, much local indifference and prejudice, peculiar perplexities and many trying circumstances, the Manchester Meeting has attained to a very high level of success. But the map provided for the guidance of strangers was so inadequate as to be almost worthless.

Manchester, as is well known, is the home of many would-be reformers, whose zeal oftentimes outruns their wit, and whose methods are apt to be conspicuous by a disregard of discretion and decency. The recent gathering has not been without its heart-burnings, but, generally speaking, discordant notes have been for a time and in great measure silenced. And this is well for visitors gain scant pleasure by watching the washing of the profession's dirty linen. But a gross breach was committed by "the powers" of the Medical Guild, who, at one of the most important social functions at the Owens College, distributed copies of their "Quarterly," containing, among much that was objectionable, serious reflection on the professional conduct of the President of the Medical Society and another greatly respected member of the College staff. Such a demonstration of "Manchester ethics" is deserving of general condemnation.

Dr. Thomas Buzzard, in opening the discussion on functional and organic paralysis, dwelt on the importance of ankle clonus and Babinski's sign as strong evidences of a definite organic lesion. The various opinions expressed well illustrated the great difficulty of adequately differentiating these cases.

Professor Curatulo, of Rome, aroused considerable interest by the description and demonstration of his new speculum, whereby the female genital organs might be exposed to the germicidal action of rays from the Finsen lamp, and lupus and epithelioma of the vagina might be submitted to treatment by the electric light.

Dr. F. W. Mott's paper on the influence of syphilis as a cause of insanity gave rise to much discussion, which focussed itself into the following practical resolution:—"That the section of Psychological Medicine thinks it ought to point out that general paralysis, a very grave and frequent form of brain disease, is largely due to syphilis, and is therefore preventable. We, therefore, the members, strongly recommend that greater efforts should be taken to moderate the transmission of syphilis and to stamp it out, and we further urge that the attention of the Legislature and of public bodies should be immediately called to this important matter."

Dr. Niven, Manchester's indefatigable medical officer of health, opened the discussion on 'Preventive Measures in Tuberculosis, in the Section of Public Medicine, and the following resolution was adopted:—"That this Section considers that the time has now come for the Local Government Board to grant more extended powers for dealing with cases of tuberculosis to such local authorities as are able to show that they are in a position to undertake the necessary work."

A noteworthy feature in the Public Health Section was the participation by two distinguished laymen in the discussion on the relation of poverty to disease. Mr. Alderman MacDougall, brother of the Chairman of the London County Council, and Mr. Seabohm Rowntree, of York. Only good can come from such cooperation.

The discussions on arsenical poisoning and the use and abuse of arsenic as a medicine were somewhat barren, no new points of importance being raised. It is to be regretted that Mr. Jonathan Hutchinson's recent suggestions as to a relationship between arsenical administration and the increase of cancer were not seriously discussed.

Dr. David Lloyd Roberts delivered an interesting address at the opening of the section of Obstetrics and Gynæcology, in which he reviewed the life work of such well-known Manchester obstetric practitioners as Charles White, John Hull, Kinder Wood, Thomas Radford, Charles Clay, James Whitehead, and John Thorburn.

General approval was expressed with the annual exhibition. Unfortunately, many of the "Association authorities" still look askance at this trade representation, and instead of trying to raise its level by "artificial selection" would seem in great measure desirous of bringing about its overthrow. Certainly there is still much room for improvement. The selection of exhibits is not always judicious, and the "ways" of exhibitors might in some instances be restricted with advantage. Although all the stands were not occupied, we understand, certain firms were "refused admission." The hall, while generally suitable, lacked all æsthetic adornment. A considerable number of the exhibitors were from Manchester and its immediate district. The show of carriages was poor and the exhibit of motors miserably meagre.

THE EXHIBITION.

The thirty-fifth annual exhibition of medical works, drugs, foods, and surgical and sanitary appliances was held in the Drill Hall, near the Owens College. The exhibits had been conveniently arranged and were thoroughly representative, and the show was well attended. Although there were few absolutely new features, old and tried preparations were attractively arrayed and the newest improvements in surgical instruments were well presented. There were about 140 exhibits, and exhibitors appear well pleased with the results of their efforts. The distribution of excursion and entertainment tickets in the Exhibition Hall, although in some ways inconvenient to members, is said to have proved advantageous to exhibitors.

Where so much is worthy of notice it is impossible to afford detailed description of the various features of interest. A brief survey is all that exigencies of space will allow. The Exhibition was formally opened by the Lord Mayor of Manchester.

Rontgen Ray and Electro-Therapeutical Appliances.

The photo-therapeutic apparatus and electrical appliances attracted much attention. The exhibit of Mr. Marshall, of Hanover Square, London, illustrating the method of treatment by electrical ozone and light and the application of currents of high potential and great frequency received much notice, and members approved the arrangement whereby no patients are to be treated without a medical man's order and under his direct supervision. It may be mentioned *en passant* that an installation for treatment has just been erected at the Royal Baths, Harrogate. The radioscopic demonstrations with Gaiffe's new apparatus were largely patronised, and Messrs. H. W. Cox, Limited, exhibited Mr. Mackenzie Davidson's new mercury break and apparatus for X-ray workers, as well as a new lamp for the treatment of lupus, of which they are the makers. The Sanitas Electrical Co. exhibited the new "Dermo" lamp for "Finsen" treatment, and other novel electrical apparatus. Dr. Brouillard's ingenious apparatus for pneumatic massage was also on show. Messrs. Mottershead and Co., of Manchester, exhibited an excellent variety of constant current batteries, X-ray apparatus, and electric motors for massage; and Messrs. Midgley, Limited, had on view an ingenious acetylene surgical lamp which can be transported from place to place with ease and is always ready for use.

Drugs and Pharmaceutical Preparations.

Messrs. C. J. Hewlett and Co. made an admirable show, which included such new preparations as acetopyrine, agurin, aspirin, heroine, thialion, and urea for the treatment of tuberculosis. Messrs. Scott and Bowne were represented by their popular Emulsion, which needs no description at our hands. William Mather, Limited, presented a well selected exhibit of their far-famed plaisters. Messrs. Corbyn, Stacey, and Co., Limited, showed Antisep, to form a new preparation for the generation of formaldehyde, hæmaformene, a new scale-like form of iron prepared from ox blood, and spirit nucis inglandis, a useful antispasmodic and prophylactic in morning sickness. The Anglo-American and Continental Pharmaceutical Co. indicated the benefits of kügloids, benzo-kinone, and other preparations. Arthur and Co. showed bromaurum, hydraurum, tamopumilio, and other useful agents. Burgoyne, Burbidges and Co. indicated the advantages of acoin, creosotal, xeroform, and some interesting new silver preparations. Zimmer and Co. brought forward euquinine, a tasteless quinine; eunatrol, eupyrine, and many important synthetic compounds. The Angier Chemical Co. were not backward in displaying their much-favoured "Angier's Emulsion." E. Summer and Co. made a great show of both pharmaceutical preparations and surgical appliances. The Bayer Co., Limited, had a large display of such important synthetic preparations as aristol, hedonal, heroin, protargol, trional, and also showed various somatose products. Hans Hoff exhibited "Ironal" and his well known malt extract. Parke Davis and Co. had an elaborate exhibit, which included Adrenalin, the active principle of the suprarenal gland, serums, toxins, medicinal elixirs, and their standardised fluid extracts. James Woolley, Sons and Co., Limited, the well-known Manchester firm, made a large and very complete exhibit, which included their sanitary powders, akolethe, phenate of soda solution, and antiseptic fumigating tapers. They also showed surgical instruments and electrical apparatus Mr. W. Martindale, of "Extra-pharmacopœia" fame, also made a very comprehensive show, which included excellent sterilised dressings and suprarenal extracts in tablet form, urea apparatus, and his well-known urine test cases. Messrs. Oppenheimer, Son and Co. showed their "palatinoids" and various concentrated liquors; Messrs. Fairchild, Brothers and Foster reminded us that the "Fairchild" products were still widely known and wisely used. Eucryl exhibited their useful toilet preparations; B. Kühn showed that much appreciated antiseptic Chinosol, papain decoction, and many organo-therapeutical preparations; Messrs. Wyleys, of Coventry, drew attention to their "Tropela," or compressed lozenges, useful ophthalmic ointment tubes, sapolette powder, which is a special soap in powder, rendered antiseptic by the addition of thymol; their standardised tinctures, and other well-known preparations; Duncan, Flockhart and Co. showed their widely-known chloroform and other products. The Chas. Phillips Chemical Co. introduced a hydrated oxide of magnesium under the name of "Milk of Magnesia."

Foods, Meat Extracts, Malt Extracts, &c.

There was perhaps a larger display in this class than in any other. "Plasmon," a recent introduction, the value of which is now so generally recognised by the profession in wasting diseases, anæmia, rickets, &c., was shown in its varied forms of powder, biscuits, cocoa and meat extracts. Messrs. Brand's popular meat extracts, meat juice, meat jellies, and lozenges and fever food were also there, and Mellin's Food Co. were represented by their renowned infants and invalids foods, food biscuits, food chocolate and cod-liver oil emulsion; and the new Essence of Mutton, "Hipi," now almost as universally known and appreciated as a change in the diet of invalids as beef extracts, was exhibited by Messrs. Nelson, Dale and Co.

Van Abbott and Sons presented foods suitable for diabetics, dyspeptics and invalids. The Universal Digestive Tea Co. urged the special virtues of their particular infusions; the Myosin Albumen Meat Extract Co. advocated the use of "Mamesin." Cosenza and Co. were there with Maggi's soups and essences. Nestlé would not allow his deservedly popular brand of condensed milk to fall into oblivion. Keen, Robinson and Co. urged the benefits of Robinson's prepared barley and patent groats as a trustworthy and nutritious diet for infants, and of Keen's mustard for adults. "Strenbo" was advertised as an advantageous meat extract. "Albene," a pure vegetable fat, was advocated by Messrs. Broomfield and Co. for all cooking and baking purposes. Billon's Ovo Lecithin was also exhibited as a new food for delicate children, and consists of stearic, oleic, and palmitic lecithin.

Callard and Co,, the invalid food specialists, made a good show, and the Manhu diabetic foods were again exhibited, and Feltoe and Stower's lime and lemon juice preparations were frequently sampled. Liebig's Extract of Meat Co. showed "Lemco," "Oxo" and "Peptarnis." The Maltine Manufacturing Co. showed their various popular malt extracts and products, and Messrs. Carnrick and Co. their well-known beef peptonoids. C. Dreyer and Co. sought attention for Swiss Brand Milk. The British Somatose Co. had an elaborate exhibit of Somatose made from beef, Iron-Somatose and Milk-Somatose, the merits of which are now well recognised by medical men; and "Virol" could not well be overlooked. This, as our readers are aware, is an emulsion of red bone marrow, malt extract, eggs and lime-juice, rich in the nitrogenous and bone-forming elements.

Various forms of mineral waters were exhibited, the most important being those of Messrs. Jewsbury and Brown, "Camwal," the Apollinaris Company, Messrs. Oppel and Company, and Messrs. Ingram and Royle. Wines by Messrs. Stephen Smith, Murray, and Sons and the South Australian Government bonded wines of the "Orion" brand. The indiscriminate use of alcoholic drinks is wisely being much restricted, but undoubtedly there is still a lack of pleasant and beneficial beverages which may adequately take their place. Manufacturers of recent years have seriously faced the problem and done much to show that non-intoxicating drinks may be provided which shall be popular and free from deleterious properties. Among the new high-class beverages is "Vinrube," which is manufactured by Camwal, Limited, and was much approved at the meeting. It claims to be made from ripe fruit, is flavoured like "claret cup," has an appearance resembling sparkling red Burgundy, and is exceeding refreshing and very palatable.

Disinfectants and various sanitary compounds were exhibited by such firms as "Jeyes" and the Izal Company. "Oowana Soap" was declared to be "supplied by special desire to H.M.S. *Ophir* for the use of H.R.H. the Duke of York and suite," and Messrs. Midgley, Limited, of Manchester, had a most interesting exhibit of medicated soaps and bath products.

Messrs. Doulton (of Doulton ware fame) had on view some novelties in the way of baths, lavatories, and water-closets. The special Hospital Bath, on wheels for the purpose of moving about from ward to ward or bed to bed, has a special wheel brake, so that the bath can be kept as firm when in use as a fixed one. Another novelty of considerable importance to surgeons was an operating lavatory with basin and top in one piece, with a waste pipe controlled by the foot. Their bath fittings for asylum use are also excellent, and so designed that they can only be actuated by a key in charge of the attendant.

Surgical Instruments and Appliances.

This branch was not so extensively represented as on some prior occasions; nevertheless, there were more than sufficient for all practical purposes. Messrs. Allen and Hanburys, who have recently added the manufacture of surgical instruments to their food and drug departments, had a large exhibit of instruments, cabinets, operation tables, bed supports, surgical electric motors, sterilisers, &c. Messrs. Down Bros. had a most attractive display, including the novel feature of an aseptic operating theatre with up-to-date furniture complete, beside recently introduced or improved surgical instruments. Messrs. Weiss and Son showed a new operation table in nickelled steel, improved instrument cabinets, sterilisers, &c., whilst the Surgical Supply Association of Manchester, which is reputed to be formed on co-operative lines by medical men, and managed by medical men, had a very extensive display of surgical instruments, trusses, bandages, poison bottles and sundries, even to crutches. Messrs. Mayer and Meltzer exhibited a portable surgical motor, designed especially for mastoid surgery and another for general surgery in hospital theatres, which attracted considerable attention. The Holborn Surgical Instrument Co. had an extensive display, and some novel and decidedly interesting cabinet and folding baths were on view by the Gem Supplies Co. Messrs. Paté, Burke and Co. exhibited their new surgical dressing, "Petanelle," in which, by a peculiarity of manufacture, the wool is rendered lighter and more absorbent than other surgical dressings. The further advantage is claimed for this material in that being derived from peat it possesses natural antiseptic and deodorant properties, and may be left on a wound with safety much longer than ordinary dressings Scotland was represented in this section by Messrs. Gardner and Son, of Edinburgh, who showed Annandale's, Chiene's, Croom's, Simpson's, and other surgical instruments, and by the Medical Supply Association of Edinburgh.

The O'Connor Extension Co. showed their excellent patent appliances for the lame, including the new support for flat foot. The "Domen" Belts Co. were represented by some particularly well and scientifically made abdominal belts and stoop-cure appliances.

Various forms of bedstead, sanitary and heating appliances were also shown. Many carriages were exhibited, chiefly by local firms. Unfortunately the exhibit of motors was inadequate.

Many of the newest books were open for examination on the stalls of such well-known publishers as Baillière, Tindall and Cox, Macmillan and Co., W. B. Saunders and Co., J. B. Lippincott and Co., William Green and Sons, John Wright and Co, of Bristol, and Rebman, Limited.

The Exhibition was worthy of the occasion. It should prove of much service to members. The catalogue was convenient in shape and will be of value for reference.

The Operating Theatres.

CENTRAL LONDON THROAT AND EAR HOSPITAL.

Temporo-Sphenoidal Abscess.—Dr. Percy Jakins operated on a girl, æt. 3½, who had been admitted into the hospital for an offensive discharge from the right ear of three years' duration; the child had on and off complained of headache, and at times had seemed stupid. However, for the first few days after admittance the headache disappeared, and she seemed brighter, but on the sixth day she became drowsy, with constant yawning and shrieking, the pupils being widely dilated; an erythematous rash appeared over the chest, right knee, and ankle. The child was immediately put under chloroform, and a semi-lunar incision was made over the right mastoid, the skin was reflected with the periosteum; the antrum was exposed, together with the mastoid cells, which only contained a little recent lymph. The lateral sinus was next exposed, it was found patent and perfectly healthy. The skull was trephined over the temporo sphenoidal region, the dura mater was slightly bulging, this was divided, and a long, thin knife carefully passed into the brain; pus immediately escaped. The wound was enlarged with a brain pus seeker, when a fair amount of pus welled up; a drainage tube was then inserted, and the patient removed to bed. Dr. Jakins said this was evidently a case of a temporo-sphenoidal abscess, and remarked that this was another sad instance which showed the danger that parents run in not having ear disease attended to at once, without waiting until serious cerebral symptoms manifest themselves; any patient, he thought, who has an offensive discharge from one or both ears, which does not improve on treatment, and is accompanied by headache, nausea, and vertigo, ought to be operated on without delay. With regard to the operation itself, he drew attention to the fact that, considering that the discharge had lasted for three years, there was so little disease found in the antrum and in the mastoid cells; the disease, he considered, must have attacked the roof of the petrous bone and so infected the temporo-sphenoidal lobe.

FRENCH HOSPITAL AND DISPENSARY.

An Old-fashioned Ovariotomy.—Mr. O'Callaghan operated on a woman (a sister) who was suffering from a large tumour; she had noticed it for about a year; it had grown very rapidly within the last year, and filled the whole abdomen, resembling a full-time pregnancy. Within the last six months she had repeated attacks of localised peritonitic pains, which was the sole cause of her seeking surgical advice. The diagnosis was that of a multilocular ovarian cyst, complicated with adhesions, as there was no mobility in the tumour. The abdomen was opened in the middle line by an incision four inches long, the hand passed into the abdomen, and the many adhesions were broken down. A trocar was plunged into the cyst, and a considerable amount of fluid drawn off, but the trabeculæ were so numerous and full of gelatinous fluid that Mr. O'Callaghan was obliged to empty the larger portion of the tumour with his hand. On delivering it the pedicle was found to be very thick, necessitating tying in three portions. Some portion of the fluid having got into the peritoneum, and the oozing from the broken down adhesions being rather profuse, it was thought advisable to leave in a Bantock's glass drain for twenty-four hours. Mr. O'Callaghan said that this ovariotomy was interesting, inasmuch that nowadays one rarely met with a cyst which had grown so large, and it was instructive because it showed the importance of prompt operation when any ovarian enlargement was discovered. As this patient, owing to her position in life (that of a sister of a religious order) had allowed this large tumour to grow to a dangerous extent, as the history and many adhesions showed, and proved by the fact that she had had several very acute attacks of peritonitis, therefore it was interesting to point out that had she been in the ordinary walk of life her condition must have been discovered long before the present time, saving her a vast amount of pain and suffering. With regard to drainage, Mr. O'Callaghan remarked that the best maxim was "when in doubt, drain," and that the best drain in deep abdominal work was a glass one. The glass drain was removed in twenty-four hours. The patient's pulse and temperature remained normal throughout, and she left hospital about a fortnight after operation.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 13, 1902.

THE EARLY DIAGNOSIS OF MALIGNANT DISEASE OF THE UTERUS.

Professor Japp Sinclair's eloquent Address in Obstetrics, at the recent meeting of the British Medical Association, which we published last week, will attract the attention of the profession to the dire disease which so far has almost completely baffled the skill of the specialist. We do not propose to follow him in his comparisons between the value of the various methods of research which must be followed in the future, or to express an opinion as to the probable route which will lead us to that "Promised Land" of ætiological certainty of which he speaks. To reach that land, a way must first be paved with clinical facts and the results of pathological investigation, and, though the opportunity for laying a stone in this pavement occurs now and then to every member of our profession, it will be some time before the road is finished. But, in the immediate present, another and equally important opportunity of benefiting the sufferers from uterine cancer is of frequent occurrence in the practice of every medical man. As Professor Sinclair tells us, our hopes of immediate amelioration of uterine cancer rest on surgery, and the possibility of the adoption of surgical methods rests in the hands of the general body of medical practitioners. The infrequency with which cases of malignant disease of the uterus, in which it is possible to adopt radical surgical methods, are now seen by the operating specialist, will in the future, when a more satisfactory state of things is reached, be almost unintelligible. The general public, at present, recognise that uterine cancer is an insidious and terrible disease, the medical profession recognise the vital importance of early diagnosis, and yet, as Professor Sinclair states, the proportion of operable cases which are seen in hospitals is about 18 per cent. The causes of this, as given by Professor Sinclair, are worthy of the most constant repetition. Briefly stated, they are: the ignorance of the patient; the lack of due insistence on the part of general practitioners on the importance of immediate local examination in suspicious cases; and popular delusions. Patients are not so well trained and disciplined in these countries as in Continental Europe, and hence, even if they consult a medical man, they hesitate to lay all their symptoms before him. Medical practitioners, even if the premonitory symptoms of cancer are hinted at or perhaps actually told, are too apt to allow themselves to be infected by the optimism of the patient, and are too ready to postpone the local examination until the boasted efficacies of some lauded drug have been found wanting. And, as if the natural ignorance of the patient and the optimism of the medical practitioner were not enough, popular delusions cloud the minds of the one and increase the difficulties of the other. Notions concerning "the change of life," "climacteric hæmorrhages," and the universality of pain in cancer, join in confusing the mind of the patient and in preventing her from submitting to the necessary examination. Indeed, we should be afraid to say how recently has the possibility of climacteric hæmorrhages been more present in the minds of many of our profession than the probability of cancer. The medical profession cannot justly be reproached because the ætiology and cure of cancer have not been discovered. Advances in our knowledge have come and will come, but they are bound to be slow. Can we, however, entirely ignore the reproach that but some 18 per cent. of cases of uterine cancer are seen whilst they are operable? So long as a medical man assumes the responsibility of treating by palliative measures cases which present suspicious symptoms, without first adopting such steps as will alone enable him to determine definitely that malignant disease is not present, so long can no inconsiderable share in the discredit which surrounds the 82 per cent. of cases which might have been cured fall to the lot of the medical profession.

THE POOR-LAW AND PADDED ROOM.

As a whole the Poor-law system of Great Britain, we are fain to believe, is administered on lines that are more or less progressive. The methods in vogue at the present day, for instance, are infinitely in advance of those that prevailed a couple of generations ago. At the same time there are blots on the present system that can only be removed at the cost of unceasing vigilance. As to many of the defects of Poor-law infirmary administration, we have felt it our duty to state our opinion in former years that not a few of them have arisen from want of proper inspection. The personal honour and competence of His Majesty's Local Government Board Inspectors are of an unassailable standard, but their methods of inspection cannot be regarded as satisfactory when tested by results. What system would have permitted such scandals as that of those of the Newton Abbott Workhouse to go on unchecked year after year? The blame for this *laisser faire* policy lies probably not so much with the inspectors as with the Local Government Board, which is content with advising when it should insist. On several occasions we have called the attention of the Board to deaths that have taken place in padded rooms attached to infirmaries in the East of London. We have made emphatic inquiries as to the absence of resident medical men, the insufficient staff of attendants, the use of restraint in improper cases, and we have strongly urged the necessity of independent and searching official inquiry. What has been the response to our representations we know not, but last week the fact that such evils still exist was proved by what the newspapers describe as "A Padded-room Tragedy" in West Ham Infirmary. The facts of the case are simple. The patient, suffering from enteric fever, was admitted to the infirmary. As deceased was delirious he was ordered a sleeping draught, and medical directions given that if he were noisy he could be put in the padded room. Deceased was later placed in the padded room and found at 1.20 a.m. with his head hanging through a hole in the door, so nearly suffocated that he died shortly after being removed from the door. The attendant appears to have made an effort to summon medical assistance, but the telephonic communication was stopped. As a matter of fact no medical man was summoned. Here we have the familiar ghastly story once more. The idea of putting a typhoid patient in a padded room in itself constitutes an act of barbarism worthy of mediæval times. The facts of the case seem almost to warrant the assumption that the lack of a proper staff of nurses prompted the action of the medical man in sanctioning the use of the padded room. The fact that the medical officer was presumably a busy general practitioner living away from the infirmary would naturally render attendants chary of summoning him to attend patients in the wards. The jury found that deceased died of suffocation, and advised that an inquiry be held into the conduct of the attendant. We are inclined to go further, and to say that the safety of the public demands a stringent examination by the Local Government Board into the circumstances of the present death, and also into the whole system of padded rooms, medical attendance, and nursing staff of the Poor-law infirmaries. We venture to hope that some member of Parliament will ask the President of the Local Government Board for a return of all the deaths that have taken place in padded rooms under their supervision during the past few years, with full details as to the name and the duties of attendants, workhouse master, nature of illness of deceased, cause of death and the system of medical attendance, and name of medical officer. It is time that an end was put once and for all to a recurrent scandal unworthy of the humane spirit of the age.

LONGEVITY.

"There is a Dr. John P. Wood, of Coffeyville, Kansas, now past his hundredth year, and still engaged in the practice of his profession. On the Piscataway Farm, in New Jersey, lives Noah Raby, said to be one hundred and twenty-nine years old." So writes Roger S. Tracy, formerly Registrar of Records in the Department of Health, New York City, in a highly interesting paper which bears the title, "Longevity in Our Time." That many lives are now prolonged, which under the conditions of a quarter of a century ago would have been inevitably lost, is an unquestionable fact. The introduction of vaccination and other forms of preventive and curative *inoculation*, including, of course, antitoxins; the discovery of anæsthesia and of antisepsis, and the recognition of the importance of cleanliness, personal and circumferential, have accomplished what may fairly be described as scientific miracles in the preservation of human life. The progress of the epidemics of infectious and contagious diseases has been effectively checked; and the surgeon now fearlessly invades every cavity and recess of the human body, when the desirability of mechanical interference happens to be indicated. In considering the question of the actual increase of longevity, there are several aspects in which it may be viewed. Do we mean by increased longevity that a larger proportion of individuals attain to the centenarian rank, or that the average age at the time of death has become greater? Are we to understand that each individual lives longer than he would have lived in the conditions of one or more centuries ago? The fact is, indeed, undeniable that the "death-rate" has of recent years been decreasing in all the civilised countries. Now the mortality in every community varies with age. In infancy it is very high, in childhood very low, from ten to fifteen years of age it is lower than at any other time of life; it then continues low, but with gradual increase, until middle age is passed, after which it rises rapidly in every succeeding decade. We find that, according to the common consensus of statisticians, the only trustworthy means of conducting this inquiry to the formation of an accurate opinion is by examination of the life-tables, by which is ascertained the "expectation of life" at each year of age. Such tables form the basis of all the calculations of insurance actuaries, and are constructed from the mean population for a series of years at the various ages, and the mean annual number of deaths at the corresponding ages. Now it is known that the contagious, infectious, and gastro-intestinal diseases, which furnish so large a proportion of fatal cases in infancy and early life, do not cause even 5 per cent. of deaths after the age of forty-five. On the other hand, the deaths of persons over forty-five from alcoholism, cancer, phthisis, diabetes, old age, apoplexy, disease of the heart, and blood-vessels, of the respiratory and digestive organs, of the kidneys and bladder, and from violence, constitute about 90 per cent. of all such deaths. In fact, the deaths from some of these causes, in spite of all our modern sanitation, have increased at such a rate as to cause much misgiving. In the city of New York the death-rate from cancer and from diseases of the kidneys (commonly known as Bright's disease) has doubled in thirty years . . . so that, in some respects, the saving of life among the young, by the partial suppression of contagious and septic diseases, tends to be counterbalanced by an increased mortality after middle life from diseases which depend more upon personal habits than upon external causes. The specimen life-tables furnished by Mr. Tracy show that during the past half-century the "expectation of life" for males at birth has *increased* by nearly *four years*. The lowering of the death-rate and the increase of the expectation of life, do not, however, necessarily imply increased longevity of the race. The saving of so many fragile young lives has the necessary effect of throwing forward into the later periods of life a large number of weakly persons, and the average stamina of the population is consequently reduced, so that when the decline of life begins, and the physical powers decay, this undue proportion of weakly lives tends to increase the mortality at advanced ages. In connection with such observations it is highly instructive as well as interesting to note that: "The Ghetto in Rome was the healthiest quarter of the city, and at the present day the Jewish quarter of New York, the most crowded and, until recently, the dirtiest part of the town, has the lowest death-rate." This Mr. Tracy attributes to the elimination of the weak during the terrible ordeals of the past two thousand years, together with their "rigid adherence to the admirable sanitary code of Moses." Mr. Tracy's conclusions are, upon the whole, encouraging: "It is certain that the average man has a better chance of living long than he ever did before in the history of the world." And he considers that "the rosiest outlook is that for the diminution of the ravages of consumption, the 'great white plague' of temperate climates." And when we are told that in the city of New York alone half-a-dozen reputed centenarians die every year, we feel some assurance that even the extremest form of pressure in the struggle for existence does not cut off all hope of attaining the honoured and much-coveted distinction of centenarianism.

The Manchester Royal Infirmary poll of the trustees has resulted in the very decisive majority of 351, out of 757 papers returned, against rebuilding on the present site.

* * *

We regret to announce the death of Deputy-Surg.-Gen. J. Watts, of the Army Medical Department (retired), on Friday at Upper Norwood, after a long illness, in his sixty-ninth year. He joined the medical service of the Army in April, 1855, and served in the Indian Mutiny campaign of 1857-58. He was placed on the retired list with the rank of deputy-surgeon-general in 1884.

Notes on Current Topics.

The King and the Coronation.

The important national ceremony of the Coronation has come and gone, and the unemotional Englishman has turned once again to the even tenour of his citizen affairs. As we ventured to predict a week ago would be the case, His Majesty King Edward the Seventh was enabled to withstand the fatigues of the ceremonial in an entirely satisfactory manner. Despite the fact that his Majesty's face bore the unmistakable trace of past illness, the popular verdict was that for an invalid he looked remarkably well. For this happy issue from a serious surgical operation he has to thank in a great measure the enduring constitution, which is, happily, a kind of birthright to the average Britisher. Then, again, without undue self-praise, we may say that he has been in the hands of the greatest surgeon of a great surgical era. The brilliant certainty of the first surgical step has been equalled, if not surpassed, by the less showy bu supremely momentous decision to allow the illustrious patient to go through the postponed ceremony in the early days of his convalescence. Whatever may be the environment of his Majesty in the near future, the nation may rest content in the wisdom of the surgical advice that will doubtless guide his actions.

The King's Prizes.

The competition for the best designs for a sanatorium for the treatment of tuberculous patients in connection with the Sir Ernest Cassel Fund has been decided. No less than 180 competitors sent in their essays to the Arbitration Committee, which consisted of Sir William Broadbent, Sir Douglas Powell, Sir Hermann Weber, and Dr. Theodore Williams. The first prize of £500, on their advice, has been bestowed by the King on Dr. Arthur Latham, of St. George's Hospital and the Brompton Hospital for Consumption, in association with the architect, Mr. William West, of London. The second prize of £200 is awarded to Dr. F. J. Wethered, associated with Messrs. Law and Allen, architects; and the third prize of £100 to Dr. E. C. Morland, of St. Bartholomew's Hospital, associated with Mr. G. Morland as architect. Four other essays are mentioned as being of great excellence; they were sent by Dr. P. S. Hichens (Northampton), Dr. Turban (Davos), Dr. Jane Walker (London), and Dr. J. P. Willis (Bexhill).

The Statutory Duties of Cabmen.

Is a cabman bound by the law to carry a fare at all times and under all circumstances? If so every citizen, at some time or other, must have had the opportunity of turning the legal tables upon cab-drivers who have taken no notice of his uplifted umbrella or his excited shouts. Is a cabman bound to take up any person regardless of the damage that may be done to his cab by the wet, muddy, or otherwise objectionable state of the fare? We trow not. The law actually fines a cabman who carries any person suffering from a notifiable infectious disorder. such as small-pox, and so admits the principle that it is not for the public weal that every citizen should have the universal right of "user" of all public vehicles. The Birmingham magistrates interpret the law on the wider basis apparently, for they recently inflicted a smart fine on a cabman who refused to carry a disabled child to the hospital. We believe, although, of course, we speak as non-legal citizens, that the cabman acted within his rights. Some years ago a woman jumped over the suspension bridge at Clifton, and fell in the mud. By some miracle she was not killed on the spot. A passing cab was hailed, but he refused unless someone would pay for the damage to his vehicle. If it be compulsory for a cabman to carry persons in such a state that his cab must be injured, then the responsibility for the damage must also be defined. It is inconceivable that the Legislature would compel the cab driver to pay for damages of that kind out of his own pocket. The Birmingham magistrates could hardly have considered the bearing of the philanthropy they were enforcing at other people s cost.

Public Vaccinators and Patients' Payments.

The medical profession throughout the United Kingdom is interested in the question of the exact position of a public vaccinator with regard to private patients who may wish to pay a fee for vaccination. The Board of Guardians at St. German's, near Plymouth, have had an official correspondence with the Local Government Board upon the matter. The central authority point out that there is nothing to prevent a public vaccinator from performing the operation and receiving a fee in his private capacity. The Board, however, disapproves of any action of the Guardians that would have the effect of suggesting to the public that vaccination and revaccination are not free to all residents within their union, irrespective of social position, who desire the services of the vaccinator in his public capacity. From this official declaration it seems that a public vaccinator is justified in taking fees from anyone who wishes to pay him. At the same time in performing a private operation, he would be committing an illegal act if he were to use Government lymph for the purpose.

The Modification of Milk in Infant Feeding.

The difficulties which arise in the artificial feeding of infants owing to the unstable composition of milk, as delivered to the consumer, are sometimes so apparently insuperable that this most excellent of all infant foods is abandoned in favour of some proprietary preparation. Professor Rotch, of Harvard University, has, at the recent meeting of the British Medical Association, drawn attention to the various ways in which these difficulties can be overcome, as well as to the importance of so doing. The exact analytical methods of modern chemistry render it now possible to be more precise in our definitions and in our formulary than was possible when the empirical methods of the nurse were universal. To copy nature satisfactorily, the physician must be able to vary the percentage of proximate principles in the substitute food he prescribes, according to the requirements of the infant. Professor Rotch gave a most interesting account of the organisation in connection with the Gordon-Walker milk laboratories in America, and pointed out the various essentials which are necessary. The first of these was to secure pure milk of good quality, of known quantitative value, and free from bacterial contamination; the second was the safe transmission of such milk without change from the source of supply to the individual infant; and the third was the capacity to vary the composition of the food as the judgment of the physician directed. We have always considered that the only method by which proper feeding can be secured to the infants of the very poor, is by the establishment of duly supervised dairies from which fresh milk can be obtained in forms suitable for infants of various ages. Such dairies should be instituted and supervised by the municipal authorities, and, if properly conducted, could be made self-supporting. We should like to draw the attention of the various philanthropic societies which are interested in such matters, to Professor Rotch's valuable paper.

Atmospheric Electricity.

THE homely and inexhaustible subject of "the weather" is almost as important and interesting to the medical man as to the meteorologist and the farmer. To its variations the average member of our profession owes a great deal of the material for his practice, as does the meteorologist for his scientific investigation, and the farmer for the rewards of his annual course of labour and speculation. One of the most important items in the list of meteorological phenomena is, of course, atmospheric electricity. There is always a demonstrable amount of electricity present in the air, but its kind, as well as its quantity, varies from time to time. The results of recent investigation go to show that careful systematic observation of the electricity of the atmosphere may be made to furnish a trustworthy index to the character of coming weather. Mr. C. T. R. Wilson, who has made careful investigations in this department of physical science, in connection with the Meteorological Office, has found that when rain is falling, or about to fall, the electrometer always indicates the presence of the opposite kind of electricity to that which prevailed when the weather was steadily fine. The rule is practically universal, that reversal of the prevailing atmospheric electricity is always connected with change from fair to rainy weather. Moisture seems to condense more readily upon particles charged with one kind of electricity than on those charge with the other. Accordingly, the idea has suggested itself that the control of atmospheric electricity might prove the means to effect climatic changes beneficial both to agriculture and to public health. Having regard to the colossal conquests which science has effected in the electric dominion during the past quarter of a century, the hope might not prove altogether Utopian that in this direction something may still be done towards the control of phthisis and chronic rheumatism, the great endemic plagues of our over-moistened islands.

Decaying Woodwork.

ALL of us know the smell—often faint and musty, but always unmistakable—of decaying woodwork. It is to be found perhaps in its most typical form in the ancient chambers of some inns, where the wood of panelled walls and flooring has been solid enough to withstand the wear and tear of perhaps a couple of centuries or more. Not all of us, however, are alive to the inner meaning of the changes of which the mustiness is the outward and sensible sign. Indeed, before the disclosures of modern bacteriology were available no adequate scientific explanation was forthcoming of the phenomenon. Nowadays we know that the peculiar micro-organisms of decaying wood are the responsible agents of the destruction. There can be no reasonable doubt that decaying wood, or the conditions that accompany that decomposition, are injurious to the health of the human being. Decay is to a great extent prevented in wooden surfaces other than the floor by preventing the access of air and moisture by coats of paint or varnish. In the floor, however, the conditions of moisture from frequent washing of rough and polished surfaces favourable to the growth and lodgment of bacteria are present. Perhaps the most urgently needed reform in dwelling-houses at present is the introduction of smooth and impermeable floors.

Safety Flannelettes.

CORONERS have for long denounced the dangers arising from the use of flannelette. Every medical man knows the suffering entailed on children by the employment of this inflammable material. During the years 1899 and 1900 inquests were held on the bodies of 1,684 young children whose deaths had resulted from burning, and in 1,425 of these cases the fire in the grate which caused the catastrophe was without a guard. But flannelette is cheap and convenient, and many mothers are poor and ignorant. Medical men may talk, but it has been left to manufacturers to act, and at last it would seem that a satisfactory advance has been made in solving the problem. At the recent Exhibition in connection with the British Medical Association, the well-known firm of Messrs. Whipp, Brothers and Tod demonstrated the properties of their new non-inflammable flannelette, which is registered under the convenient title of "Non-Flam." The experiments, which were closely watched by large numbers of medical men, conclusively proved that the new material will not readily ignite either before or after washing, and that it never flashes. The nature of the material is not altered as regards its softness and comfort, and it does not in any way injure the skin. We venture to think that in this new preparation of cotton a means of removing, or at least greatly reducing, a danger to child life has been discovered, and since this "Non-Flam." flannelette can be supplied at a cost very little above that of the now popular but terribly dangerous material, it should speedily become universal. Medical men would do well to obtain some of the new safety flannelette and test its properties for themselves.

A Burglar Posing as Medical Man.

The plans of an ingenious burglar have recently been disclosed by the police in a prosecution at Liscard. The gentleman in question is described as an habitual thief. In order to cloak his proceedings he took rooms in a furnished house and stated he was a medical man attached to the Stanley Hospital, Liverpool. In pursuance of that alleged occupation he was in the habit of going out at night and not returning until the next morning. Unfortunately for himself he was not content with out-of-door operations but annexed the watch of a fellow lodger. The incident reads like a page from a sensational romance.

Canada: the New Nursery of the Human Race.

The great Dominion of Canada is rapidly becoming the refuge of the restless and adventurous, or of the rejected, citizens of the other nations. From even the prosperous and progressive neighbouring republic of the United States there has been an annual exodus of thousands during the past few years. This includes large numbers of Mormons; and the phenomenal industry, by which this very "peculiar people" have always been distinguished, is, we are informed, making the desert of their settlement—in Alberta—to, literally, blossom as the rose. Ten years ago the Census reported 86 per cent. of the inhabitants of the great Dominion as native-born; while 10 per cent. were born elsewhere under the British flag, and only 3 per cent. were absolute foreigners. We have now no less than forty nationalities represented among the immigrants of recent years: Arabs, Austrians, Belgians, Bohemians, Chinese, Danes, "Doukhobors," Dutch, English, Finns, French, Galicians, Germans, Greeks, Hebrews, Hungarians, Icelanders, Irish, Italians, Moldavians, Newfoundlanders, Norwegians, Poles, Portuguese, Roumanians, Russians, Ruthenians, Scotch, Slovacks, Spaniards, Stundists, Swedes, Swiss, Syrians, United-Staters, Welsh, West Indians, and so on. The *Doukhobors* are a sect of Russian Quakers of whom nearly 10,000 came to Canada in a body in 1899. Among the immigrants are also reckoned 30,000 Galicians and 40,000 Slavs; thus are the most widely diversified peoples coming to find their Land of Liberty and Home of Refuge in the vast prairies of Western Canada. What an immense and productive nursery in the future development of the human race has thus been opened out! Hundreds of villages are now springing up on those previously unbounded plains; agriculture, stock-raising, and road-making are progressing with giant strides. And here we are bound to have some of the most important problems in the evolution of the human race, now in their embryonic stage of existence, gradually developing for the future study of the legislator, the ethnologist, the moralist, and—the pathologist.

Itch or Eczema—or Both?

It is curious how slow the public is to realise that a medical man cannot be punished for a simple error of professional judgment Before any legal action can be sustained against him on the ground of mistaken diagnosis or treatment it must be shown that there has been also either gross negligence or want of an ordinary and reasonable amount of skill. In the face of this firmly-established principle, any client must be extremely ill-advised if he bring an action for malpraxis against a medical man except upon the clearest evidence of culpable negligence or ignorance. In a case tried recently at the Birmingham Assizes, the plaintiff, named Furstenant, a coal contractor, was wanting in both the essentials named, to say nothing of the minor qualities of charity and reasonableness. In August last, so the story ran, he suffered from a skin eruption, for which he consulted Dr. Tomlinson, who treated him for eczema. In October, finding he was not cured, he went to another medical man, who told him he was suffering from itch. Later, his wife contracted the complaint. Mr. Tomlinson, on the other hand, stated that he had the idea of itch in his mind on first seeing plaintiff, but he failed to discover any sign of that disease. The jury found an immediate verdict in favour of Mr. Tomlinson. Everyone conversant with medical matters knows the extreme difficulty that often surrounds the diagnosis of itch when masked with severe or generalised eczema. Indeed, every skin specialist falls into the pit sooner or later. It is only by a process of exclusion that a definite diagnosis can be arrived at in many chronic cases, a kind of inference that is necessarily slow.

A New Qualification for Medical Men.

The average candidate for the post of Poor-law medical officer is, we fear, a most optimistic person, who considers that he can sustain life, and work hard, on the honour conferred by his appointment, and who sometimes even thanks the country farmer who has appointed him for having done so. We wonder, therefore, how he will regard the new qualification which he is called upon to possess. The Board of Guardians of the Tullamore Dispensary District have announced that at the forthcoming election of a Poor-law medical officer they will give the preference to a candidate who is a Member of the United Irish League. That is to say, it will not suffice that a candidate for a medical position shall possess all the needed medical qualifications, but he must also place his political conscience in the hands of the guardians of the poor who appoint him. In return for the possession of the necessary qualifications—both those required by law and those not required—the Guardians will award him a salary of £100 per annum, occupy his time fully with the work for which this salary is paid, and then allow him to live—if he can. Now, as we are not a political journal we are in entire ignorance as to what may be the meaning of the demand of the Tullamore Board of Guardians, but we do know that to demand of a candidate for a post—the salary of which is paid out of the public purse—that he be a member of a political organisation, lawful or unlawful, is an insult to the medical profession. Further, it is a devotion of the public money to the furtherance of the objects of a political organisation in a manner which is far from right, and we fancy illegal. The election in question will take place before this journal is published, but in the event of the adherence of the guardians to the terms of their advertisement, we call upon the Local Government Board to declare the election void, and if they do not see their way to adopting such a step we trust the Irish Medical Association will call the attention of Parliament to the matter.

Delenda est Anopheles!

The opening attacks of the war to the death which has been commenced against the pestiferous mosquito are reported in encouraging terms from the opposite side of the Atlantic. "The result of the successful work in 1901 on Center Island, near Oyster Bay, has led to a plan of action covering a territory about fifteen miles long and five miles wide, and preliminary work has already been completed. Professor Charles B. Davenport and Mr. Frank E. Lutz, of the University of Chicago, each with an assistant, have made an entomological survey of the region, locating every water surface and determining and reporting the kind and extent of larvæ in the breeding-places." This is certainly going to work with the energy and enthusiasm which "deserve success"; and which, we venture to add, in the present instance must ultimately secure it. As in the case of all other great movements which have been initiated for the genuine improvement of the physical welfare of humanity, this work on Center Island at first received a great deal of opposition from the inhabitants, who were to be the permanent gainers by the transactions involved. The work has so far consisted mainly of the carrying out of drainage and the application of petroleum. The latter is the temporary agent of relief and requires but slight application. The use of the former must be thorough, for it is to it that we must look for the permanent cure. Eight oil stations were established on the island, and at each one or two barrels of petroleum were arranged on a platform in the shade of trees. From each, the petrolier having armed himself with his knapsack sprayer filled with petroleum from the barrel, sallied forth to scatter destruction among the enemy. Needless to say that the carrying out of this campaign to a successful issue is a laborious task. Water is absolutely necessary for the breeding of the mosquito, and the knowledge of this fact furnishes a light which illuminates the whole position. And we are glad to say that the reports of the results being obtained are thoroughly encouraging. Mr. Henry Clay Weeks, an authoritative expert on the subject, announces that "The writer has been informed that, in other years, to drive along the borders of this marsh was a perilous undertaking to man and beast, but he walked over it many times during and after the work, and did not encounter a single mosquito." The drainage, of course, was a troublesome and expensive proceeding; but the result well repays. The mosquito must disappear from the borders of civilisation: in time from the face of the earth. Delenda est!—our title *must be* correct in its latinity, as *the* enemy is *female.*

Smoke Nuisance in America.

The smoke nuisance has been recently receiving a good deal of municipal attention in some of the large cities of the United States. New York, indeed, has since the application of its smoke-destroying law in 1898, enjoyed the immense physical advantage of existing within and beneath an aerial atmosphere which is probably the clearest and purest of any great city in the world. The railroads entering New York are compelled to use coke instead of soft coal for their engines, to bring the trains within and to withdraw them from, the limits of the Metropolis. At present date, Boston exists under a smoke law which permits the production of black smoke for five minutes at a time, and for an aggregate period of three hours in twelve. This law is, of course, quite insufficient for the production of even an approximately clear atmosphere; and, accordingly, an agitation has been set on foot to procure a law compelling every manufactory to prevent or consume its smoke. In the earlier periods of the history of the great New England cities, the large proportion of water power, and, subsequently, the use of an anthracite coal, kept them practically free from the plague of sootiness. The introduction of soft coal in recent years has had the effect of making American city atmospheres distressfully like those of the "old country." The discussion on the smoke question in Boston has also had the good effect of bringing into prominence the fact that the combustion of their own soot will be actual economy to manufacturers; and that the better preservation of buildings, trees, and so on, to say nothing of human health, will be a source of genuine saving to the whole community.

Crises in Diseases.

The following statement hails from an American source:—"Long ago much importance was attached by medical men to a certain day in the course of a disease as being critical, that is, as marking the probable occurrence of the crisis. . . . The blind belief prevailed for centuries, in spite of the rude refutation that it must often have met in every day experience; in our times, however, it has altogether been abandoned." Has it, altogether? We do not know that the average case-history of typhoid and pneumonia, to take two of the most common diseases, does not occupy a certain given time, and does not present a certain sequence of events, among which is a strong tendency for the morbid process to have run through its more acute stage by the twenty-first and ninth days respectively. Whether this constitutes a crisis in the meaning of the *New York Medical Journal* is one thing, but in Europe we are still content to look upon it as such. The writer speaks airily of the rude refutation that this "blind belief" must often have been met with in every day experience, but he conveniently says nothing of the more numerous cases in which the "blind belief" was confirmed. Less happy still, however, is the writer when he remarks further on: "In the case of infectious diseases, including the septic contamination that may follow wounds, we feel simply that the patient's chances of recovery improve with each day. . . ." Since when has the "septic contamination that may follow wounds" been included with infectious diseases? And whoever would expect to find a crisis in the case of a poisoned wound? This fashion of sneering at everything in the past is evidently not always happy in its deductions.

The Part Played by Vaccination in Preventing the Spread of Small-pox.

AN interesting and important discussion at the recent meeting of the British Medical Association, on the precise part played by vaccination as carried out in this country in preventing the spread of small-pox, resulted in the adoption of two important resolutions. The first of these reads:—"That inasmuch as there is strong evidence to show that the effect of infant vaccination has largely lost its influence after ten or twelve years, it is desirable that all children should be revaccinated at the age of 12 years." The second was as follows:—"That in the opinion of this section the duties of the administration of the Vaccination Acts should be transferred from the Poor-law authorities to the county and county borough authorities." The evidence which was brought forward by the speakers in support of the former of these resolutions would go far to convince any honest and at the same time sane opponent of vaccination of his wrong-headedness. We venture to say that never in the history of any prophylactic measure has such definite proof of utility been obtained, but still vaccination is opposed, not merely by isolated individuals here and there, but by bodies of men supposed to be representative. It is generally recognised that if a series of identical phenomena possess but one circumstance in common, that circumstance is the cause of the phenomena. Still, though the confessed diminution in the size and virulence of small-pox epidemics has but one attendant circumstance common to all epidemics, *i.e.*, the adoption of vaccination and revaccination, the British public as a body appears to be opposed to the recognition of vaccination as the cause of the diminution. In other words, for reasons which to the intelligent observer are non-apparent, a certain section of the British public prefers to court the mortality which attended the Gloucester epidemic than to ensure the almost complete immunity of an Irish city, where the anti-vaccinationist does not exist.

The Teaching of Surgery.

DR. HERBERT L. BURRELL, of Boston, who wrote in January, 1901, a circular letter to the different medical schools in the world asking for information regarding the methods of teaching surgery, recently read a paper before the American Surgical Association on what, in his opinion, should be the essentials of instruction in this subject. Dr. Burrell classified the information he had received from the different medical schools under no less than eighteen heads. His conclusion is that "America in surgery stands to-day sorely in need of men who are equipped and fitted by scientific methods to advance surgery. Students should be taught along scientific lines by instructors who are completely equipped." It is not quite plain what the writer means by "men who are equipped and fitted by scientific methods," unless it is men bristling with the latest forms of surgical appliances. However, it is not safe to assume that he means exactly what his English would convey, inasmuch as in another place he states that a student's education should include, among other things, "the minimum required fundamental knowledge." Somehow, "fundamental knowledge" sounds as if it was something of which one could not have too much.

Examination Fever.

A CONTINENTAL authority has recently shown that candidates for examination are wont to lose flesh when undergoing that ordeal, a conclusion which will not surprise the medical world. We have little doubt that a careful physiological investigation would show a variety of further changes in the nervous and other systems of the body. The effect of a high standard examination is much the same as that of an infectious fever. The appetite fails, the sufferer is sleepless, he becomes pale, listless, and loses flesh rapidly. Many a time have we noted these changes in a robust, country-bred young man, who has developed the signs of examination fever as surely as if he had been down with a bad attack of typhoid. Fortunately the convalescence in these cases is as rapid. Five or six weeks spent at the seaside or in the country suffices to bring round the wasted frame of the examinee to the *status quo ante*. Were it otherwise, the moral burden of high standard examiners—heavy as it already is, if we are to believe the heavy indictments launched against them—would become unbearable. The way that students regain their health after these most unwholesome intellectual contests affords a striking testimony to the stamina of British youth.

A New Cure for Glycosuria.

To the long list of remedies for glycosuria is now added the infusion of the dried leaf of the eucalyptus. The fresh leaf has been used with benefit for some years past in Australia, and it occurred to Dr. Faulds to try the effect of the infusion of the dry leaf. He writes very favourably of its therapeutic effects. Of forty-six cases treated fifteen are reported as cured. The curative properties must be resident in the leaf, for the oil has no curative action on the disease; neither has the eucalyptus gum, which almost altogether consists of tannic acid.

PERSONAL.

SIR DYCE DUCKWORTH gives the opening address of the Owens College Medical School at the beginning of the Winter Session in October next.

THE Bissit Hawkins Gold Medal has been awarded by the Royal College of Physicians of London to William Henry Power, F.R.S., Principal Medical Officer to the Local Government Board.

MAJOR RONALD ROSS has received a shower of recognitions of his distinguished researches on the transmission of malaria by mosquitoes. Among the latest is the Cameron prize in therapeutics of the University of Edinburgh.

WE are reminded that the Law Fund is not yet closed, and that a meeting of its supporters will be held shortly. Dr. Paramore, of Gordon Square, London, W.C., the honorary secretary, will be pleased to acknowledge any subscriptions.

DR. BACCELLI has recently been presented with a presentation shield in appreciation of his discovery of the aphtha epizoötica of cattle. This distinguished member of the medical profession holds the portfolio of the Ministry of Agriculture with a seat in the Italian Cabinet.

DR. DAVID FERRIER has been appointed by the Royal College of Physicians of London, Harveian Lecturer for the year; Dr. Cullingworth, Bradshaw Lecturer; Dr. Grünbaum, Gulstonian Lecturer; Dr. T. R. Glynn, Lumleian Lecturer for 1903; and Dr. J. R. Bradford, Croonian Lecturer for 1904.

Special Correspondence.

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

GRADUATION CEREMONIAL AT EDINBURGH UNIVERSITY.

THIS year's graduation ceremony will be memorable in the annals of the University as the occasion of the conferring of honorary degrees on the Colonial Premiers. It is singularly fitting that this, perhaps the most cosmopolitan of British Universities, so far, at least, as its undergraduates are concerned, should take the lead in honouring the Colonial Premiers in this fashion, inasmuch as the Colonies send it annually a large proportion of its students. The degree of LL.D. was conferred on General the Right Honourable Lord Grenfell, Governor of Malta; the Right Honourable Sir Joseph West Ridgeway, Governor of Ceylon; Sir Edmund Barton, Prime Minister of the Australian Commonwealth; the Right Honourable Richard John Seddon, Prime Minister of New Zealand; Lieutenant-Colonel the Right Hon. Sir Albert Henry Hime, Premier of Natal; the Right Hon. Sir Robert Bond, Premier of Newfoundland; Sir Walter Joseph Sendall, Governor of British Guiana; Sir William Macgregor, Governor of Lagos; the Right Hon. Sir John Gordon Sprigg, Premier of Cape Colony; and the Right Hon. Sir Wilfrid Laurier, Prime Minister of the Dominion of Canada. Of Sir William Macgregor the Dean of the Faculty of Law said:—"Our illustrious compatriot furnishes in his life and work an inspiriting illustration of what can be accomplished by a Scottish graduate of medicine. Having taken his degree in the University of Aberdeen, he began his career as a Resident in the Glasgow Royal Infirmary. Thereafter he held a succession of medical appointments under the Government at the Seychelles, Mauritius, and Fiji, and I would mention here that it has not been by the physicians' arts alone that he has proved a benefactor, for he holds the Albert and Clarke medals for gallantry in saving life at sea." After the recipients of honorary degrees had been capped, various degrees in medicine, science and arts were conferred, and prizes and scholarships awarded. The degree of M.D. was granted to sixty-seven graduates, and that of M.B., Ch.B., to a hundred and forty-one, in both instances a number of women being among the recipients. The customary address was delivered by Professor Schäfer, who prefaced his speech by sundry remarks on the best methods of employing the earlier years of professional life, and the altruistic spirit which the practice of medicine tends to produce in the characters of those pursuing it. Successful leaders of armies were recompensed, and rightly so, not only with titles, but with still more tangible marks of gratitude and appreciation. But though "A wise physician, skill'd our wounds to heal, Is more than armies to the publick weal," almost the only instance of pecuniary reward being conferred on a medical man for public service was the Parliamentary grant of £30,000 to Jenner for the introduction of vaccination. Speaking of the changes in medical problems which the increasing knowledge of the last half of the nineteenth century brought with it, Professor Schäfer said that those whom he was addressing were fortunate in that it was not probable that during their lifetime would there occur any such complete change in the manner of viewing nearly all the problems of medicine and surgery as had been the case in that of their predecessors of his (the speaker's) own generation. The doctrine of the parasitic nature of disease bears a no less important relation to medicine than the principle established by Darwin does to biology. The problems of health and disease must be attacked in the future, as in the past, by the method of experiment, for clinical and pathological observations in man are, as a rule, by themselves insufficient for the definite establishment of any important principle in medicine. The problems which are at present offering themselves most prominently for solution are of a chemical nature. The chemical characters of the products which the disease-parasites form in the body, their physiological action, and their mode of formation, and the chemical characters, modes of formation, and actions of the ante-products which are formed by the organism for purposes of defence are all questions awaiting solution. The subject is one requiring a thorough mastery both of chemistry and physiology and pathology, a combination which is almost unknown, in this country at least. The difficulty must be met by the establishment of chairs of physiological and pathological chemistry, to be occupied by men who are primarily chemists, but who also have some knowledge at least of physiology. In this matter, as in others, University College, London, has been a pioneer, a chair of pathological chemistry having been established there in 1896, in which the first occupant, Professor Vaughan Harley, notwithstanding deficient accommodation, equipment, and finances, has done most excellent work. With this exception there has hitherto been no chair in any British

University dealing with this important branch of medical science, although the Universities of Oxford and Cambridge have established lectureships on physiological chemistry. But it has been left to one of the newest Universities—University College, Liverpool—to lead the van in this movement, and to endow a chair of biological chemistry, through the munificence of one of the citizens of Liverpool. The need for such a chair at Edinburgh is very evident, and no one entertains a doubt that when we recognise and state our needs the means of providing them will be forthcoming.

It may be mentioned as an interesting feature of this graduation that for the first time in living memory one of the warders carried the ancient unwieldy bâton or staff, which is perhaps several hundred years old. It is made of rosewood, is silver mounted, and has on it a shield with the University arms. It was discovered lately by the chief janitor, stowed away among some lumber, and was, through the intervention of Sir Ludovic Grant and the University Clerk, restored and again made fit to be carried in a procession.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

GARLIC AND PHTHISIS.

To the Editor of The Medical Press and Circular.

Sir,—It may be of interest to Dr. Minchin to learn that my experiences with garlic, like his, have been favourable. I first drew attention to the value of garlic (especially in cases of diluted bronchi (with fetid expectoration) in a clinical lecture delivered at University College in January, 1894. This lecture was published in the *Clinical Journal* for January 31st, 1894, and was incorporated in a volume entitled "Nervous Affections of the Hand and Other Clinical Studies," published by Smith and Elder in 1897. The remarks on garlic will be found on pp. 274—280. I am inclined to say that I have more often seen improvement occur after garlic than after any other internal remedy.

I give the crude, raw vegetable, chopped up in salad, or bread sauce, or beef tea. If the patient dislikes the flavour I give it in rice-paper cachets. Many hospital patients relish garlic immensely, while others loathe it. To these latter it seldom proves useful.

I have read Dr. Minchin's letter with much interest, and have thought that he and your readers might be glad to have a reference to the experiences of others.

I am, Sir, yours truly,
G. V. Poore.

24a, Portland Place, W., August 10th, 1902.

PROLONGED NITROUS OXIDE ANÆSTHESIA.

To the Editor of The Medical Press and Circular.

Sir,—I have read with great interest Dr. Kirkpatrick's able paper on "Prolonged Nitrous Oxide Anæsthesia by Paterson's Method," which was published in The Medical Press and Circular of July 16th. Dr. Kirkpatrick's modification of Paterson's apparatus is obviously a very great improvement on the original, the disadvantages of which Dr. Kirkpatrick describes so lucidly, and which therefore I need not repeat. I feel bound, however, to point out that the underlying principle of either method is a wrong one, inasmuch as it depends upon the necessity of supplying gas at the anterior nares under considerable pressure; for, to use Dr. Kirkpatrick's own words, "I had to return to Paterson's original model of the nose-piece, so that by increasing the pressure in the gas bag I was able to raise the gas pressure in the naso-pharynx to such an extent that the soft palate was pushed forward against the tongue, so closing the mouth-way from behind. . ." This means that all the cavities of the nose, with its accessory chambers and sinuses, are forcibly distended with gas, with the attendant risk of setting up inflammation, particularly if there already be a condition of catarrh existing at the time of the administration, for it would thus be an easy matter to blow disease germs from the nasal meatus into the frontal sinuses or maxillary antra. The upper meatus are not used in normal breathing, but when gas or air is forced into these passages under pressure, a very unpleasant feeling is experienced in these regions during the administration, which often causes shouting, struggling, or other signs of excitement, not infrequently followed by acute frontal headache after recovery from the anæsthetic. Not only this, but there is also the great disadvantage of the necessity to keep the nose-piece fitting accurately, which hampers both operator and anæsthetist; while the apparatus is distinctly in the way of the former, particularly while operating on the front of the maxilla or upon the right side of the mandible.

Although I am fully alive to the excellent anæsthesia it is possible to attain, in many cases, by Dr. Kirkpatrick's method, yet I am strongly of opinion that the principle is not a good one, and should not be adopted so long as there are means of obtaining as good results without the attendant risks to which I have alluded.

I am, Sir, yours truly,
Harvey G. Gilliard.

30, Wilton Place, S.W., July 31st, 1902.

PROFESSOR McHARDY'S ESCAPE.

To the Editor of The Medical Press and Circular.

Sir,—In your last issue you alluded briefly to the stirring adventure of Mr. McHardy. The news of the incident had already reached the world through the medium of the lay newspapers, and from the latter point of view I venture to ask permission to append a few remarks. In these days when everything that savours of undue publicity with regard to the social life of medical men is unsparingly condemned, it behoves us to inquire into the cause of such publicity when it occurs, with a view to future prevention. In this case it must have been clearly due to the indiscretion of Mr. Philip Herbert, who rescued his friend from a watery grave. Mr. Herbert's discretion, however, has apparently not been equalled by his caution. The information to the newspaper men must have presumably come from him, for it is hardly likely that any of the yachtsmen would have communicated with the Press. The information must have come from someone intimate with Mr. McHardy's private affairs, for it was announced to the world not only that the rescued gentleman was professor of ophthalmology at King's College, but also that he held the post of senior surgeon of the Royal Eye Hospital, St. George's Circus, London. The wonder is that this incautious friend did not add to the completeness of the record by giving the Professor's private address, with particulars of past appointments.

Heaven preserve us from our friends!

I am, Sir, yours truly,
Honi Soit.

London, August 8th, 1902.

P.S.—The statements as to the present appointments I have seen both in a London evening paper and in the *Yorkshire Daily Post*. The latter says the Professor will be well enough to resume professional work after the holidays.

SUNSTROKE AND DIETARY.

To the Editor of The Medical Press and Circular.

Sir,—Pray allow me one word of correction as regards my letter on this subject and your comment thereon.

The word "thin" was omitted before "cranial bones," which made all the difference, as my point was that in India, although the bones of the skull were thin and the hair fine and closely plastered down (in contrast with the woolly-haired, thick-skulled negro races), yet sunstroke was uncommon among the hardy classes who ate sparingly and took but little fluid.

I do not suggest that sunstroke is *common* among horses, but that while it occurs not unfrequently among highly-fed draught horses in cities like New York and London, it is almost unknown among animals in their hardy wild state.

The problem therefore that I raise is whether the "microbic cause" of sunstroke answers the difficulties of the case, and I only modestly suggest that the presence of much fluid in the tissues, which canbe considerably affected by extreme temperatures, may have also some predisposing cause.

It appears to me that there is sufficient probability to make it worth while suggesting that fruitarianism and total abstinence may have an effect on tending to prevent sunstroke, in so far as they encourage the use of a drier dietary and discourage the imbibition of excess of liquids.

I have the honour to be, your obedient servant,
Josiah Oldfield, D.C.L. (Oxon.), M.R.C.S.
5, Harley Street, W.

Obituary.

SURG.-LIEUT.-COL. H. LAMB, R.A.M.C.

We regret to announce the death of Surg.-Lieut.-Col. H. Lamb, of the Royal Army Medical Corps, who died on Saturday of angina pectoris, at Thorpe Lodge, Shirley, Southampton, at the age of sixty-four. He joined the medical service of the Army in October, 1860. He served during the New Zealand War and the Zulu Wars, for both of which campaigns he had the medal.

Literature.

CLIMATE AND BATHS OF GREAT BRITAIN. (*a*)

The first chapter in this book, by Dr. Wm. Ewart, treats of the climate of London and Middlesex. The information is well condensed and full of interest and encouragement for all dwellers in London and its vicinity.

London air, water, and fogs are all subjects very fully discussed, and some interesting results as to variations in purity of the air and causation of fog are brought to the reader's notice. The meteorological tables, extending over ten years, represent much labour and observation, and bring out numerous comparative facts as to temperature, rainfall, &c. The first chapter would form a very valuable little book if issued in separate form.

The second chapter, on the climate of the East Coast, by Dr. Wm. Murrell, treats of the climates of Essex, Suffolk, Norfolk, and part of Lincolnshire. The rising watering places of these counties receive fair and impartial notice.

In this, as well as in subsequent chapters, it will be noticed how the authors, while not unmindful to record average temperatures, elevation, dryness of soil and air, and so forth, give also information as to the diseases prevalent in each locality. They also indicate the cases that are not likely to do well at certain stations.

The bracing tonic air of the East Coast is getting a good name for curing cases of phthisis. At Mundesley-on-Sea is the well-known sanatorium of Dr. Burton-Fanning, where the open-air treatment is most thoroughly carried out. In cases where there is tendency to bronchial spasm and asthma this East Coast air is often too stimulating, while the more sedative air of London is well known often to relieve markedly. We rather wonder that this is not alluded to by the writer. Dr. Plowright, of the West Norfolk and Lynn Hospital, gives the death-rate from phthisis as 1·1 per 1,000 of population; further statistics show that this disease is more influenced as to prevalence by moisture of the soil than by its special composition.

With regard to the prevalence of calculus, Dr. Plowright finds that in High Norfolk, that is east of the Ouse, one case occurs in 2·5 square miles; while in Marshland, west of the river, one case occurs in 8·2 square miles. In Marshland the natural water supply contains a large amount of salt, and salt increases the solubility of uric acid.

The climatology of Lancashire, by Dr. Maguire; of the Midland counties, by Dr. Horton Smith; and of Northumberland, Yorkshire and the Lake District, by Drs. Lazarus Barlow and Brooksbank, teaches much that is worth learning by all.

North Wales falls to the share of Dr. Leech, and Dr. Theodore Williams treats very completely of the South Wales climates. The tables of rainfall and of isothermal lines given in this article bear witness to the care and industry of the writer.

The concluding part of the book, from the pen of Sir John Moore, describes fully the climate of Ireland, and Dr. Norman Moore gives a short chapter on the mineral springs of that country.

As the Report of the Royal Medical and Chirurgical Society of London this work is one of great value and utility.

The reports are drawn out with care, being based on replies to circular letters sent out to medical men in the various localities, and the work of arranging the information thus obtained must have been considerable. The tables and maps have been executed with attention and deserve all praise.

ELEMENTARY ZOOLOGY. (*a*)

The fact that the date of the preface to this second issue of Mr. Masterman's "Zoology" follows that of the preface to the first edition by an interval of less than one year is, probably, the very best practical testimony to the fact that the text-book before us has been found to fulfil—definitely and usefully—the function for which it was intended by its author when he undertook the preparation. As the writer very sensibly remarks in the preface to the first issue of this work: "It is questionable whether it is possible to provide the student with a book which can entirely take the place of oral instruction." He judiciously emphasises the importance of practical instruction; and, of course, everyone who knows anything of any scientific subject knows that it is only as an adjunct to practical instruction that any text-book can be used with genuine profit. It is with this fact in his mind's eye that he tells us: "Hence I have written the descriptions of the types in this book, and in the majority of cases have drawn the figures, with the animals (or the parts of them) before me, in order that the work may be found an aid to dissection as well as a preparation for written examinations." It is, of course, somewhat humiliating—if not aggravating—to a specialist to have to admit, as in the present instance, that "our whole system of zoological classification is in such confusion that the adoption of any particular scheme appears at present to be purely arbitrary." But we consider that he has acted with the best discretion by maintaining "a very definite limit to the introduction of new features of classification or even of new types." Having regard to the wants of students, for whom it was primarily intended, we consider that the author has made a most judicious and conscientious selection of his material; and that, used in connection with the oral and practical instruction - in which we will presume that the author is as finished an adept as he is in the book-wright department—the present volume must be allowed to offer a very fair approximation to the features of the hopelessly unattainable perfect scientific text-book. In this second edition the author has inserted about fifty new figures, and added a short description of a type of rotifera. A careful revision of the text and former figures has, however, enabled him to keep the volume to practically the same bulk as before, without omission of anything essential. With such indications of its general features we leave this attractive manual—looking forward to the appearance of a third edition in 1903.

(*a*) "The Climate and Baths of Great Britain, being the Report of a Committee of the Royal Medical and Chirurgical Society of London." By C. Theodore Williams, M.D., Chairman, P. Horton Smith, Hon. Secretary. Vol. II.—Climates of London, Central and Northern England and Ireland. London: Macmillan and Co., Ltd. New York: The Macmillan Society. 1902. Price 12s. 6d.

(*a*) "Elementary Text-book of Zoology." By Arthur T. Masterman, M.A.Cantab., D.Sc.Lond., D.Sc.St.And., F.R.S.E., Lecturer on Zoology and on Biology in the School of Medicine of the Royal College, Edinburgh. Second Edition. With 441 Illustrations. Crown 8vo. Pp. xxiv. and 628. Price 12s. net. Edinburgh: E. and S. Livingstone. 1902.

THE HEALTH ASPECTS OF LINEN WORKERS. (*a*)

This portly octavo of x. and 463 pages contains the reported results of a skilled professional investigation of the conditions of existence connected with the manufacture of linen in Belgium. The verdict arrived at is that the occupation of those employed "dans les filatures de lin" is an insalubrious one, but that the degree of unhealthiness varies greatly with the particular employment in which the individual is engaged. In their conclusions the authors of this report condemn employment at too early an age, working at night and on the seventh day, resumption of labour too soon after parturition, and the careless ventilation of the apartments in which the combing is carried out. "Le travail de cardage est le plus insalubre de ceux qui s'exécutent dans les linières." We are also told that "Le filage du lin à l'eau chaude est une opération très insalubre; les filles et les femmes qui s'exécutent sont, en grande majorité, atteintes d'un certain degré d'anémie." The work is richly illustrated by a series of photo-lithographs of the special departments of linen factories. And there are excellent ones of "Eczéma lichénoïde des fileuses de lin (mains en griffes)," "Dermite ulcéreuse des fileuses de lin (degré léger)," " . . (degré moyen)," " . . degré extrême," "Retraction permanente de l'auriculaire," and "Ulcere traumatique des fileuses de lin." The volume is, throughout, a very instructive one.

THE PERITONEUM. (*b*)

This portly and well-printed octavo is the first instalment of what promises to be by far the most exhaustive work on the peritoneum which the world has yet seen. It is well written and copiously illustrated. The author—a most refreshing characteristic, which carries the over-read reviewer breezily over the pages of a new scientific book—has evidently dealt with his subject *con amore*. The *occasional* author who does so does not himself feel weary of his self-imposed task; and, accordingly, does not convey that very infectious yawn to his reader. By the way, we cannot help observing in this connection that to us, year by year as we are growing older, that "occasional" author to whom we have just referred is growing more and more occasional with every successive revolution of the earth in its orbit; in fact, we have now come to regard his appearance as an accident. At his present rate of progressive disappearance we should be disposed to prophesy his complete extinction by the middle of the twentieth century.

In his preface the present writer tells us that "The present volume in the outcome of a half-dozen years of personal labour in experiments on the peritoneum, in the study of its anatomy and in microscopical research. The labours of others have been consulted and credited." And we cordially congratulate Dr. Robinson on the result of his labours, as so displayed to the scientific world. The contents of this volume surely represent the well-spent efforts of half-a-dozen years. It is only those of us who have made some efforts in parallel directions who can ever form even an approximately just opinion on such questions.

The first chapter of the volume before us is devoted, we are glad to see, to a "Historical Sketch." The "occasional" medical practitioner who possesses a tolerable knowledge of the history of his profession is perhaps even a rarer specimen than the "occasional" scientific writer to whom we have already referred. We consider that no man—or woman—should be allowed to practice our profession who is not *devoted* to it in the highest sense of the word. And how anyone can be devoted to so engrossing an object, without making every effort to know its past history as well as its present attractions, is far more than we can comprehend.

Dr. Robinson has given us a very interesting sketch of the work of the principal contributors to the common fund of our knowledge of the structure and functions of the peritoneum. We found it a little strange, however, not to meet the name of Winslow, nor any allusion to his "foramen," in a historical sketch of the progress of the discovery of peritoneal structure.

In the second chapter, the author opens to us the wide field of the "Anatomy and Physiology of the Peritoneum," which he treats with the hand of a past master of his subject. The third chapter deals with the "Endothelia of the Free Peritoneal Surface"; the fourth with "Subperitoneal Tissue"; the fifth with the "Blood Vessels of the Peritoneum"; the sixth with its "Lymphatics"; the seventh with its "Nerves"; the eighth with its "Physiology"; the ninth with "The Technique"; and the tenth and concluding chapter is devoted to "A Résumé of the Physiology of the Peritoneum." A splendidly-exhaustive "Bibliography" of the subject concludes the volume. In the necessarily narrow limits of a notice like the present it is idle to attempt to criticise in detail the individual sections of the work of a master who has left his readers so little to criticise. The work is exhaustive, and, so far as can be, original; and we trust that it will be read as widely as it deserves. Its subject is of the greatest practical as well as theoretical importance; the historic cases of the late President M'Kinley and of his Majesty Edward VII. have emphasised its importance to the last degree—to professional readers on both sides of the Atlantic.

SCHAFER'S ESSENTIALS OF HISTOLOGY. (*a*)

The sixth edition of Professor Schäfer's well-known manual will prove even more valuable to students than the former editions. It has been considerably enlarged, partly by additions to the text and partly by the provision of new illustrations. A full description of the central nervous system, in accordance with the results of modern investigations, has been added. The book is so well known that it is unnecessary to review it at length. For the convenience of students it is divided into forty-six divisions, each of which is intended to serve as a separate "lesson." As it is an elementary work, all unimportant details are wisely omitted, and, as a rule, references to authorities are similarly treated, while only those methods are recommended which experience has demonstrated to be of value. The illustrations are particularly good, and are well chosen. Professor Schäfer's work will long continue to be the standard text-book for students.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last monthly list:—

Baillière, Tindall, and Cox (London and Dublin).

Death and Sudden Death. By Prof. P. Brouardel and F. Lucas Benham, M.D., B.S.Lond. Second Edition. Pp. 336. Price 10s. 6d. net.

A Manual of Practical Medical Electricity, the Rontgen Rays and Finsen Light. By Dawson Turner, B.A., M.D., F.R.C.P.E. Third Edition. revised and enlarged (University Series). Pp. 396, with 168 illustrations. Price 7s. 6d. net.

Aids to Practical Dispensing. By C. J. S. Thompson. Third Edition, enlarged, with illustrations (Students' Aids Series). Pp. 92. Price 2s. 6d. cloth, 2s. paper.

Aids to Dental Anatomy and Physiology. Second Edition. By Arthur S. Underwood, M.R.C.S., L.D.S., Professor of Dental Surgery in King's College, London. Pp. 124. Price 2s. 6d.

The Journal of Obstetrics and Gynæcology. Vol. I., January to June, 1902. Pp. 713.

Chicago Medical Book Company (Chicago).

The Peritoneum. By Byron Robinson, B.S., M.D. Pp. 510, with 247 illustrations.

J. and A. Churchill (London).

A Textbook of Medicine. Vol. II. By Charles Hilton Fagge, M.D., F.R.C.P., and Philip Henry Pye-Smith, M.D., F.R.S. Fourth Edition in two volumes. Pp. 1050. Price 21s.

A Manual of Bacteriology, Clinical and Applied, with an Appendix on Bacterial Remedies, &c. By Richard T. Hewlett, M.D.

(*a*) "Les Filatures de Lin." Etude d'Hygiène Professionelle. Rapport d'Enquète présenté a M. le Ministre de l'Industrie et du Travail. Par le Dr. D. Gilbert, Inspecteur-Médecin du Travail à l'Administration centrale. Bruxelles. 1902.

(*b*) "The Peritoneum." By Byron Robinson, B.S., M.D.Chicago, Ill. Part I.—Histology and Physiology. With 247 illustrations. Imperial 8vo. Pp. 406, with 103 pp. of Bibliography. Chicago: Chicago Medical Book Company. 1899.

(*a*) "The Essentials of Histology, Descriptive and Practical, for the Use of Students." By E. A. Schäfer, LL.D., F.R.S., Professor of Physiology in the University of Edinburgh; formerly Jodrell Professor of Physiology in University College, London. Sixth Edition. Pp. xi. and 416, with 463 illustrations. London: Longmans, Green and Co. 1902.

M.R.C.P., D.P.H. (London). Second Edition. Pp. 533. Price 12s. 6d.

The Force of Mind or the Mental Factor in Medicine. By Alfred T. Schofield, M.D., M.R.C.S., &c. Pp. 309. Price 5s. net.

Clinical Essays and Lectures. By Howard Marsh, F.R.C.S. Pp. 303. Price 7s. 6d.

St. Thomas's Hospital Reports. New Series. Edited by Dr. Hector Mackenzie and Mr. G. H. Makins, C.B. Pp. 445. Calendar 127. Price 8s. 6d.

Ventilation as a Dynamical Problem. By W. N. Shaw, F.R S. Pp. 24. Price 1s.

Henry J. Glaisher (London).

Eczema and its Congeners. By Edward Blake, M.D. Pp. 136. Price 3s. 6d.

Small-pox: How it is Spread and How it may be Prevented. By James Wallace, M.A., M.D.Aberd. Pp. 69. Price 2s. 6d. net.

Charles Griffin and Company, Limited (London).

Diseases of the Organs of Respiration. By Samuel West, M.A., M.D., F.R.C.P. In two volumes, with numerous diagrams and illustrations. Pp. 913. Price 36s. net.

Lippincott and Company (Philadelphia and London).

A Practical Treatise on Small-pox. Illustrated by Coloured Photographs from Life. By G. H. Fox, A.M., M.D., with Collaborators. In Two Parts.

International Clinics. Vol. I. Edited by Henry W. Cattell, A.M., M.D., with Collaborators. Pp. 306. Price 10s. 6d.

Longmans, Green and Company (London).

Report of the Yellow Fever Expedition to Para of the Liverpool School of Tropical Medicine and Medical Parasitology. By H. E. Durham. With illustrations and plate. Pp. 79. Price 7s. 6d.

Macmillan and Company (New York and London).

Clinical Psychiatry, a Text-book for Students and Physicians. By A. Ross Defendorf, M.D., of Yale. Pp. 420. Price 16s.

Young J. Pentland (Edinburgh and London).

Text-book of Anatomy. Edited by D. J. Cunningham, F.R.S. Illustrated with 824 wood engravings from original drawings, many in colours. Pp. 1309.

The Edinburgh Medical Journal. Edited by G. A. Gibson, M D., F.R.C P. Ed., and Alexis Thomson, M.D., F.R.C.S.Ed. Vol. XI. Pp. 604.

W. B. Saunders and Company (Philadelphia and London).

Illustrated Medical Dictionary, with Pronunciations, Derivation and Definition. By W. A. N. Dorland, A.M., M.D. Pp. 770. Price 19s.

Scottish Medical and Surgical Journal, Limited.

Vol. X. January to June. 1902. Edited by Norman Walker, M.D., F.R.C.P.Ed., and Harold J. Stiles, M.B., F.R.C.S.Ed.

Smith, Elder, and Company (London).

Medical Lectures and Aphorisms. By Samuel Gee, M.D., F.R.C.P. Pp. 296. Price 6s.

Societe d'Editions Scientifiques (Paris).

De la Conjunctivite Granuleuse. Par le Dr. Z. Hourmougiades. Avec Preface par le Dr. A. Trousseau.

Williams and Norgate (London).

Studies in Heterogenesis. By H. Charlton Bastian, F.R.S., M.D. Part Second, with 244 illustrations. Price 7s. 6d.

Medical News.

New Examination System of the Institute of Chemistry.

We are glad to learn that the important step has been decided upon by the Institute of Chemistry of holding examinations in Dublin at which chemists and others may present themselves for examination. These examinations will be held at the laboratories of the Royal University of Ireland, in Earlsfort Terrace. The next intermediate and final examination of the Institute, in Ireland, will be held in July, 1903.

Apothecaries' Hall, Ireland.

At the annual meeting of the General Council of the Apothecaries' Hall, Ireland, on August 1st, the following were elected to hold office for the year ending July 31st, 1903:—Governor, Geo. A. Stritch; Deputy-Governor, Arthur Atock, M.D. Directors: Hugh A. Auchinleck, F.R.C.S.I.; John Evans, L.R.C.S.I.; William V. Furlong, L.R.C.S.I.; Thomas D. Finucane, M.D.; Edward F. Hanrahan, M.B.; Michael F. McNamara, F.R.C.S.I.; Robert Montgomery, M.R.C.S.E.; Robert John Montgomery, M.B.; Richard G. O'Flaherty, M.B.; James Raverty, L.R.C.S.E.; James Shaw, L.R.C.S.I.; Joseph Ryan, L.R.C.S.Edin.; C. R. C. Tichborne, L.R.C.S I. Representative on the General Medical Council: C. R. C. Tichborne, L.R.C.S.I. Secretary: Robert Montgomery, M.R.C.S.E.

The Society for the Study of Disease in Children.

The following office-bearers have been elected for the Session 1902-1903.

Council:—Henry Ashby, M.D. (Manchester), Fletcher Beach, M.B., Herbert L. Carre-Smith, Edmund Cautley, M.D., Wayland C. Chaffey, M.D. (Brighton), Clinton T. Dent, M.C., Walter Edmunds, M.B., Leonard G. Guthrie, M.D., Robert Hutchison, M.D., Francis Jaffrey, T. Sinclair Kirk, B.Ch. (Belfast), David B. Lees, M.D., Charles J. Macalister, M.D. (Liverpool), Lewis Marshall, M.D. (Nottingham), Robert G. McKerron, M.D. (Aberdeen), Henry Betham Robinson, M.S., A. Ernest Sansom, M.D., George E. Shuttleworth, M.D. (Richmond, Surrey), Harold J. Stiles, C.M. (Edinburgh), George A. Sutherland, M.D., James Taylor, M.D., Alfred H. Tubby, M.S., Richard H. A. Whitelocke, C.M. (Oxford), William A. Wills, M.D.

Honorary Treasurer: R. Clement Lucas, B.S.

Honorary Secretaries: Sydney Stephenson, C.M., George Carpenter, M.D. (London), Theodore Fisher, M.D. (Provincial).

New Zealand and the University of London.

Mr. Seddon, Premier of New Zealand, has cabled home the announcement that out of four exhibitions and gold medals offered at the recent intermediate examination in Medicine of the University of London three have been secured by New Zealanders studying at Guy's Hospital. Mr. A. B. O'Brien, who obtained the exhibitions and medals for both anatomy and chemistry, is the captain of the Guy's Hospital Rugby Football Club, whose team are the holders of the Inter-Hospital Challenge Cup. Mr. R. W. Allen, the exhibitioner and medallist in Materia Medica, was this year the winner of the quarter-mile race in the Inter-Hospital Sports competition.

Royal College of Physicians of London.

At the ordinary quarterly *comitia* of the College the following were selected examiners in the subjects indicated for the ensuing collegiate year:—Chemistry and chemical physics—J. M. Thomson, F.R.S., H. Forster Morley, D.Sc., F.C.S., Harold B. Dixon, F.R.S., F. D. Chattaway, Ph.D., D.Sc., and H. M. Kellas, F.C.S.; Materia medica and pharmacy—F. Willcocks, M.D., E. C. Perry, M.D., W. E. Wynter, M.D., H. A. Caley, M.D., and F. W. Tunnicliffe, M.D.; Anatomy—B. C. A. Windle, M.D., and A. M. Paterson, M.D.; Physiology—R. A. Young, M.D., J. S. Edkins, M.B., and L. E. Hill, M.B.; Medical anatomy and the principles and practice of medicine—F. De H. Hall, M.D., Sir Isambard Owen, M.D., S. H. West, M.D., P. Kidd, M.D., J. Abercrombie, M.D., Nestor Tirard, M.D., Donald MacAlister, M.D., S. P. Phillips, M.D., William Pasteur, M.D., and J. R. Bradford, M.D.; Midwifery—A. L. Galabin, M.D., G. E. Herman, M.D., Amand Routh, M.D., W. R. Pollock, M.B., and E. Malins, M.D.; Public health—A. P. Luff, M.D., and W. H. Hamer, M.D.

Royal Army Medical Corps.

The following were mentioned in Lord Kitchener's recent official despatch:—Surg.-Gen. W. H. McNamara, M.D., C.B., C.M.G., Lieut.-Col. H. H. Johnston, M.D., Lieut.-Col. H. J. R. Moberley, Lieut.-Col. F. W. Trevor, M.B., Lieut.-Col. S. H. Carter, M.B., Lieut.-Col. G. E. Twiss, Lieut.-Col. O. Todd, M.B., Lieut. Col. G. T. Goggin, Lieut.-Col. R. Jennings, M.D., Lieut. Col. J. M. Irwin, M.B., Lieut.-Col. G. W. Brazier-Creagh, C.M.G., Maj. S. Hickson, M.B., Maj. C. Birt, Maj. M. P. C. Holt, Maj. M. W. Russell, Maj. C. H. Burtchaell, M.B., Maj. F. W. C. Jones, M.B., Maj. J. R. Mallins, M.B., Surg.-Maj. J. F. Bateson (Coldstream Guards), Maj. T. G. Lavie, Capt. W. W. O. Beveridge, M.B., Capt. A. F. Tyrell, Capt. J. C. Jameson, M.B., Capt. G. St. C. Thom, M.B., Capt. W. E. Hardy, Lieut. T. C. MacKenzie, Lieut. W. A. Woodside, Lieut. L. W. Harrison, M.B.

Royal Army Medical Corps (Militia).—Capt. A. F. Benson.

A New Pathological Scholarship.

It was mentioned at the meeting of the British Medical Association, recently held at Manchester, that Mr. J. Francis Mason, of Freeland Lodge, Woodstock, Oxfordshire, had, through Dr. Caverhill, of Edinburgh, offered a scholarship of £200 a year, with extension to two or three years if further study seems to promise good results, for the purpose of carrying on investigation into the physiology and pathology of the thymus gland, including, if necessary, collateral investigation on the other ductless glands. The founder of the scholarship has associated with himself Dr. Caverhill and Prof. Woodhead to act as a small committee for the purpose of selecting a suitable candidate. In filling up the scholarship preference will be given to those who have already made a study of the thymus or other ductless glands, or have given some evidence of their fitness to carry on this or similar work, and who will devote the whole of their time during the tenure of the scholarship to the special research mentioned. Every facility for carrying on this work in the Pathological Laboratories, Cambridge, will be placed at the disposal of the scholar.

London Hospital Medical College Prize List.

At the distribution of the prizes and certificates to the successful candidates for the Session 1901-1902, the following were awarded:—Price scholarships, in science, £120, J. Owen; in anatomy and physiology, £60, H. T. Thompson. Entrance science scholarships, £60, A. H. Pollard; £35, E. H. R. Harries. Buxton scholarships, arts, £30, B. R. Billings; £20, L. Edwards. Epsom scholarship, C. H. Scott. Clinical medicine, £20, scholarship, C. U. Aitchison; honorary certificates, E. H. Harrison and R. Spearman. Clinical surgery, £20, scholarship, F. S. Kidd; honorary cerrificates, J. H. Porter and W. W. Holtzmann. Clinical obstetrics, £20, scholarship, J. E. Frere; honorary certificate, H. R. Cran. Andrew Clark prize, £26, C. E. Ham; honorary certificate, L. Bousfield. Senior Letheby prize, £20, R. Milne; honorary certificates, E. J. Roberts and A. Salmon. Junior Letheby prize, £10, E. H. R. Harries; honorary certificates, S. J. A. Beale and A. H. Pollard. Sutton scholarship, £20, A. C. Le Rossignol; honorary certificate, H. W Kaye. Hutchinson prize, £35, A. W. S. Fisher. Anatomy and physiology, £25, scholarship, R. Milne; honorary certificate, R. A. Worthington. Anatomy and biology, £20, scholarship, J. Owen; honorary certificate, E. H. R. Harries. The usual minor prizes were also awarded.

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, August 2nd, 1902, represent an annual mortality of 22·7 in every 1,000 of the population. There were thirty deaths from diseases of the respiratory system, nine from diseases of the circulatory system, sixteen from diseases of the nervous system, and eighteen from measles. In the city proper the death-rate in the Clarence Street, North district, the South East Street district, and the Grand Canal Street district were 29·4, 25·3 and 26·9 per 1,000 respectively.

St. John Ambulance Association and the Coronation.

The St. John Ambulance Association, whose resources for the rapid treatment of accidents have become an absolute necessity in times of great public rejoicings, made unique arrangements for the handling of cases during the Coronation festivities. At every available nook and corner a small ambulance party was stationed whose resources, comprising ambulance, stretchers, bandages, splints, and supplies of "Oxo" (Liebig Company's Meat Extract) were as complete as the necessarily limited space would permit. The Association renders signal service at such times as these, when accidents are far more numerous than individual observers can conceive.

Medical, Sickness, and Accident Society.

The usual monthly meeting of the committee of the Medical, Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on 25th ult. There were present Dr. de Haviland Hall in the chair, Dr. J. B. Ball, Mr. Fredk. Wallace, Dr. M. Greenwood, Mr. J. Brindley James, Dr. W. Knowsley Livesey, Mr. Wm. J. Stephens, Dr. Fredk. S. Palmer, Mr. H. P. Symonds, Dr. A. J. Rice Oxley, Dr. Walter Smith, and Dr. St. Clair B. Shadwell. The records of the Society during the first six months of this year show the business to have been exceptionally active. The advantages which membership in the Society confer are beginning to be better realised by the medical profession, and the number of new entrants is increasing. A considerable number of the present members are applying to have their assurances raised to the largest amount, £6 6s. per week, at present allowed by the rules, and there seems to be a general desire to increase the scope of the business in this direction. The sickness claims have been somewhat heavy, a considerable number having arisen from accidents caused by riding and rowing and not a few by cycling, and in some cases the injuries sustained have been severe. A substantial addition has, however, been made to the funds of the Society, which now amount to nearly £160,000. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Cancer Research.

Messrs. N. M. Rothschild and Sons have contributed, through Sir Alfred Cooper, F.R.C.S., a donation of £1,000 to the Cancer Research Fund now being raised under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England, of which fund the Prince of Wales is the president.

Cholera in the Far East.

Cholera is spreading from Manchuria to the Amur region. Last week there were 161 cases, and 101 deaths at Blagovestchensk.

Presentations to Dr. D. F. Rambaut, Richmond Asylum, Dublin.

On Friday last, at the Richmond Hospital, Dr. D. F. Rambaut, late clinical assistant, was presented with several handsome and valuable gifts from the different sections of the Richmond Asylum staffs on the occasion of his appointment as Medical Superintendent of the Salop and Montgomery Asylum at Shrewsbury. The presents included a handsome silver cup from the medical officers, tea service from the clerical and working staff, a beautifully illuminated address and silver cigar case from the attendant staff, some pieces of silver from the patients. In presenting a very handsome bowl, the gift of his medical colleagues, to Dr. Rambaut, Dr. Conolly Norman, resident medical superintendent, said that the staff were sorry to lose Dr. Rambaut, but all were glad of his promotion, and they heartily congratulated him. Several Irishmen had occupied positions at the head of English asylums, and of late years the Richmond had sent assistant medical officers trained in wards to asylums all over the sister island, north, south, east, and west, and to a great scientific hospital in London it had recently sent a former clinical assistant, who had also made his mark in a famous German laboratory. Dr. Rambaut is the first assistant medical officer who has been appointed directly to the superintendency of an English asylum. Dr. Rambaut replied in suitable terms. He was going to what he might call Dr. Norman's latest colony in England, for without Dr. Norman there would be no Shrewsbury.

Pass Lists.

Conjoint Examinations in Ireland.

The following candidates have passed the Final Examinations by the Royal College of Physicians and Royal College of Surgeons:—

Final Examination (passed in all subjects).—T. A Dillon, Miss H. A. Hall, Miss M. E. M. Logan, J. J. Moore, W. B. A. Moore, J. Murphy, J. Murray, M. A. A. O'Brien, J. O'Doherty, C. E. O'Keeffe, G. C. Robinson, F. C. York.

Completed the Examination.—H. M. Clarke, T. P. Cormack, Jas. Dwyer, R. W. Richards, G. J. Sexton, J. H. White.

Diploma in Public Health.—J. D. Wynne, M.B. (Honours), R. D. Booth, M.B., C. D. H. Rygate, M.R.C.S., Hugh Woods, M.D.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

W. A. Smith (Oxoniensis).—If the cancer be inoperable you had better try what can be done by the use of the X-rays or the high-frequency current. Really wonderful results have been reported with both methods in cases that have been given up as hopeless. Hardly any case of cancer need be regarded as too far gone to admit of some chance of successful treatment. This kind of treatment, moreover, almost invariably affords relief from the pain and from the distressing symptoms that render life intolerable. If you wish we can communicate the name of a medical man who is an expert in both kinds of treatment.

CANCER RESEARCH.

An advertisement will be found in another column for a General Medical Superintendent in connection with the Cancer Research Fund. The amount of remuneration is not stated, but as the gentleman appointed will have to devote the whole of his time to the duties of this very important office, and for which very special knowledge and training are necessary, the salary attached should be a handsome one. We would suggest to the Executive Committee that if the proposed remuneration were stated, it might determine the class of candidates for the post.

Stockton (M.D.).—No system of clothing can be regarded as observing the elementary rules of common-sense unless it is pervious to the sweat-at any rate to the insensible sweat. On the other hand, it is obviously farcical to make collars, braces, and ties of permeable material. No really scientific handbook exists so far as we know, upon this important subject; nor do we for the moment recall any competent writer likely to do justice to it.

Dr. Denham.—Your letter will appear in the next number of our supplement.

Appointments.

Coaker, F. W. J., F.R.C.S.Eng., L.R.C.P.Lond., Medical Officer of Health for Bromsgrove Rural District, Worcestershire.

Edwards, Arthur Spencer, M.B., C.M.Edin., Medical Officer of Halling District of Strood Union and Public Vaccinator for the same District.

Ettles, W. J. M., M.D.Aberd., Medical Officer of Health for District No. 11 of the London County Council.

Fisher, Charles, M.B., B.S.Durham, M.R.C.S., L.R.C.P., Deputy Poor-law Medical Officer and Public Vaccinator to the Albury District of the Guildford Union.

Goodman, Godfrey, L.R.C.P., L.R.C.S.Irel., Diploma of State Medicine, Ireland, Medical Officer of Health for Glanford Brigg Rural District, Lincolnshire.

Howie, P., M.B., C.M.Aberd., Medical Officer to the Aberdeen Dispensary.

MacKenzie, W. S., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health for Normanton Urban District, Yorkshire.

Martin, Ernest W., M.B., Ch.B., Assistant Physician to the Sanatorium, Crooksbury Ridges, near Farnham, Surrey.

Meggs, T. Hugh E., M.R.C.S., L.R.C.P., Public Vaccinator of the Slough District, Eton Union.

Monro-Home, G. H., M.D.Edin., Honorary Anæsthetist to the David Lewis Northern Hospital, Liverpool.

Nicholson, E., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Urban District Council of Fenny Stratford.

Sweeny, William James, M.B., B.Ch., B.A.O. Royal University, Ireland, Deputy Medical Officer for the Hornby District and Workhouse (Gloucestershire).

Valentine, W. A., M.D., B.Ch. Univ. Dubl., Surgeon and Agent of Sick Quarters, under the Admiralty, Appledore, Devon.

Vacancies.

Bury Infirmary.—Junior House Surgeon. Salary £90, with board, residence, and attendance. Applications to the Hon. Secretary, Dispensary, Knowsley Street, Bury, Lancashire.

Cancer Hospital, London.—Pathologist. Salary £250 per annum. Applications to the Secretary at the Hospital, Fulham Road, S.W.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £130, rising to £160, with board, furnished apartments, laundry, &c. Applications to the Medical Superintendent.

Dundee Sanatorium for Consumption.—Medical Superintendent. Salary £250 per annum. Applications to Thos. Thornton, Hon. Secretary, City Chambers, Dundee.

Gravesend Hospital.—House Surgeon. Salary £90 per annum, with board and residence. Applications to F. H. Stevens, Hon. Secretary, 146, Milton Road, Gravesend.

Halifax Union Poor-law Hospital.—Resident Medical Officer. Salary £160 per annum, with apartments, rations, and washing. Applications to Arthur T. Longbotham, Solicitor and Clerk to the Guardians, 4, Carlton Street, Halifax.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist. Salary £200, with furnished rooms. Applications before September 1st. (See Advt.)

Lanark County, Middle Ward District. — Resident Physician, Middle Ward Isolation Hospital. Salary £140 per annum, with board, &c. Applications to the Subscriber, J. B. Ferguson, Hamilton.

Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum, with board and apartments. Applications immediately to Sam. B. Leicester, Secretary, 56, Vauxhall Road, Liverpool.

Liverpool Stanley Hospital.—Third House Surgeon. Salary £70 per annum, with board, residence, &c. Applications immediately to the Chairman of the Medical Board.

Nottingham General Dispensary.—Senior Resident Surgeon. Salary £200 per annum. Furnished apartments, attendance, light, and fuel are provided. Applications to Secretary, Martin Snell Preston, Journal Chambers, Nottingham.

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £120 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

St. Andrew's Hospital for Mental Diseases, Northampton.—Junior Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Urlingford Dispensary District and Workhouse Hospital.—Temporary Medical Officer. Salary £3 3s. per week for the former, and £1 1s. per week for the latter office. Immediate application to M. P. Dowling, Clerk of Union. (See Advt.)

Births.

Clark.—On August 3rd, at 51 Parliament Hill, Hampstead Heath, N.W., to Dr. and Mrs. L. Pierce Clark—a daughter. U.S. papers, please copy.

Watson.—On August 7th, at 3 Mount Ephraim Road, Tunbridge Wells, the wife of George Trustram Watson, F.R.C.S., of a daughter.

Marriages.

Bond—Nunneley.—On August 7th, at Holy Trinity Church, Gray's Inn Road, by the Rev. F. Thorne, M.A., Rector, William Arthur Bond, M.A., M.D.Cambridge, Medical Officer of Health for Holborn, eldest son of W. Bond, Shrublands, Heigham, Norwich, to Constance Louisa, eldest daughter of E. M. Nunneley, Orlingbury, Northamptonshire.

Penton—Green.—On August 7th, at the Parish Church, Langham, Essex, Lt.-Col. Hugh Penton, D.S.O., (R.A.M.C., P.M.O. Egyptian Army, to Kathleen Rosa, youngest daughter of Lt.-Col. R. S. Green and Mrs. Green, of Stonylands, Dedham, Essex.

Thyne—Young.—On August 6th, at Metheringham, William Thyne, M.A., M.D., Barnet, to Kate Christian, youngest daughter of the late Thomas Young and Mrs. Young, of Roewath, Cumberland.

Death.

Henery.—On August 6th, at Bath, Edmund Thornton Henery, M.B.Cantab., of Plantation Providence, Berbice, in his 82nd year.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m. Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. AN OPERATION FOR GALL-STONES,

WITH THE AFTER-HISTORY OF A SERIES OF CASES OPERATED UPON. (a)

By RUTHERFORD MORISON, M.B., F. R.C.S.,
Surgeon, Royal Infirmary, Newcastle-on-Tyne.

IN a previous paper (b) I drew attention to the anatomy of the right hypochondrium in relation to gall-stone surgery, and suggested then that an incision in the transverse direction was better than the vertical one usually advocated.

In the wards of the late Dr. John Duncan, of Edinburgh, I saw for the first time an incision in the transverse direction; but the one he used was not strictly transverse, it was oblique, for it skirted the costal margin and it was short. My incision is transverse, is long, and is designed to expose the pouch I described by opening up the space between the liver above and the transverse colon below.

The weight of authority is still, so far as I can judge from the published papers, all in favour of operation through an anterior vertical incision in or about the linea semilunaris. The object of my paper is to emphasise more strongly than before my suggestion that this is not the best approach.

The operation I am about to describe allows of free access to the gall-bladder and its ducts with a minimum of disturbance of the abdominal viscera, free drainage is assured by it, and the chances of hernia of the scar are less, I believe, than when the incision is vertical.

The skin incision, when a difficult common duct operation has to be done, begins one inch below the tip of the twelfth rib and ends in front in the middle line, at the upper part of the middle one-third of a line drawn from the ensiform cartilage to the umbilicus. All the layers of the abdominal wall, including the rectus muscle, are divided, and the cut edges of the peritoneum are caught in clip forceps. A thick gauze pad or sponge is then packed into the abdomen under the lower flap of the wound over the colon and omentum, shutting off access to the general peritoneal cavity in this direction, and on the inner side and in front the stomach is covered and protected by a gauze pad.

The wound may be more thoroughly opened out by making the ilio-costal space convex to the right and pushing the hips and shoulders to the left.

Drainage is secured by indiarubber tubing, which, in the case of the gall-bladder, is fixed to it by a catgut suture, and a thick gauze strand brought through the wound posteriorly, the gauze being essential to secure the patency of the opening left. Drainage of the common duct is effected by leaving the opening in the duct unsutured with a large tube apposed to it.

Drainage of the hepatic and common ducts by a tube in the lumen does not appeal to me. A tube in the healthy rectum or nose or urethra is badly tolerated, and it seems improbable that the inflamed biliary ducts would be an exception to this rule, and possible that stricture might follow ulceration produced by prolonged tube pressure. If a soft drainage tube be used alone it soon becomes kinked from the tendency of the ext. oblique muscle to draw the opening in it upwards over the ribs.

In the paper previously mentioned I pointed out that biliary fistula not infrequently followed suture of the gall-bladder to the abdominal wall as a reason why this should never be done. The wound is closed either with four tiers of catgut or with two of catgut and one of silkworm gut. The first layer of catgut brings together at the sides the peritoneum, fascia, transversalis and internal oblique muscles, the second the external oblique muscle, the third secures the fat and skin subcutaneously to the external oblique, the fourth is subcuticular for the skin edges. If silkworm gut is used the first layer of deep far distance interrupted sutures attach the skin to the ext. oblique muscle, and bring the skin edges together roughly; the second intermediate interrupted sutures through the skin edges complete the apposition. In front the rectus muscle and aponeurosis receive the same care. To form a just estimate of the value of such an operation we require not only the information that the patient recovered from it, but to know the after-history for some considerable time.

To one who has not attempted such work as this it may seem easy enough, but in a colliery district patients are constantly "flitting," and we have found it to be no mean task. Our efforts to trace a case have too often been unavailing, but in all probability the accompanying table of after histories, for which I am indebted to Mr. G. Grey Turner, Surgical Registrar, Royal Infirmary, Newcastle, represents our average results, for every case we could find is recorded in it.

The total number of cases available is forty-three

All with the exception of the first two were operated upon by transverse incision.

The results generally confirm the surgical belief that gall-stone operations in the majority of cases are followed by permanent relief and by great improvement in the general health. They also bear out the expectation of every one acquainted with the results of post-mortem examination of gall-stone cases that in some instances stones will be left behind after the most careful and thorough operation, for it is impossible to remove stones from some of the hepatic ducts or stones embedded in certain parts of the liver.

(a) Read before the British Medical Association Meeting, Manchester, August, 1902.

British Medical Journal, November 3rd, 1894.

The first consideration was given to the question of recurrence of symptoms after operation, and the conclusion forced upon us was that a return of the symptoms meant gall-stone trouble.

Of the forty-three patients seven complained subsequent to operation. In one case (2) a stone was known to be left in at the time of operation. The patient was very ill, and the operation an early experience.

In two cases (8 and 5) recurrence of symptoms was probably due to new stone formation, for there was no relapse till four years and six years after operation.

Case 8 is of special interest because the gall-bladder and cystic duct with an impacted stone were excised.

In one case (7) it is not certain that stones were the cause of the illness as none were found at a second operation, though the symptoms were so typical that our belief was that the last stone had been passed just before it.

Three cases remain, and of these it is certain in one (Case 16), highly probable in two (Cases 27 and 39) that stones had been overlooked at the operation.

Case 16 is of great importance in this connection. The patient recovered from the first operation so completely, and improved so materially in condition, that no one suspected anything wrong. All this time, however, there was a large stone lodged in one of her ducts. The stone was of hazel nut size. It could not have been left in her gall-bladder, as that was fully slit up and explored; it could not have been in her common duct, as that was sufficiently dilated to allow of examination by my finger down as far as the duodenum and up as far as the hepatic ducts. That it had been left, and probably in a hepatic duct, was proved by the previous operation and by the facet upon it, yet the operation "cured" the patient for nine months.

It is not possible to say that operation will "cure" all gall-stone cases, but as a rule with few exceptions it may be stated that any stones left after operation will be of small size and unlikely to cause serious illness.

Careful inquiry was made as to the presence or absence of hernia of the scar.

A hernia of the scar was found in four of the forty-three cases. In Case 1, small vertical incision, gall-bladder sutured to skin, a hernia was present. In Case 5 the hernia resulted from insufficient suture. The patient was so ill that the wound was brought together roughly by a few through and through interrupted sutures. In the remaining two cases (24 and 39) defective suture was the obvious cause, as in both the hernia was outlined by the scars of an interrupted through and through suture of the posterior part of the wound, the portion in front, which had been more carefully apposed, being quite strong.

ON THE VALUE OF BLOOD EXAMINATIONS IN CASES OF ABDOMINAL DISEASE.

By C. NEPEAN LONGRIDGE, M.D., CH.B. VICT., M.R.C.S.ENG., L.R.C.P.LOND.

THE value of blood examination as a guide to prognosis and treatment is beginning to be widely recognised in this country; in abdominal, especially appendix cases, it is of special value, since experience shows that it is often impossible to diagnose correctly the exact condition and state of the inflamed parts. The leucocyte count gives valuable information as to the progress of the disease: in the majority of cases a more or less accurate knowledge is, of course, gained by ordinary examination, but there remains a minority in which the clinical signs are an insufficient guide. In these the leucocyte count is of especial value.

The method consists in counting the red and white cells together, in the erythrocyte pipette of the Thoma Zeiss hæmocytometer; a mixture of 1-200 is made, the diluting fluid used being Toisson's, which, while not affecting the red cells, stains the white a deep purple colour, so that the two can be counted together on the slide. The reds are counted by means of the squares, the whites by the "field method." Films are stained with Jenner's stain and 500 leucocytes counted in order to arrive at the differential counts. The leucocytes met with are the polymorphonuclear, lymphocytes, hyalines and eosinophiles. Haldane's hæmoglobinometer was used in cases where the hæmoglobin was estimated.

Leucocytosis is a sign of acute inflammation provided that

(*a*) Resistance of patient is capable of reaction,

(*b*) Intensity of infection is capable of exciting reaction.

The outcome of these factors means that a large leucocytosis will be provoked where the patient is in a high state of resistance and the infection severe, while a patient in a low state of resistance will under the same circumstances exhibit but a feeble leucocytosis. The balance of these factors may later on be of value in determining the prognosis of a case. The author is not prepared to state that any definite relation exists between the intensity of the infection and the amount of the leucocytosis. The pathological question of the source of the leucocytes is of great interest, whether, as Virchow and Ehrlich believe, their excessive number is due to stimulation of those organs which produce them; or whether, as von Limbech and Jakob hold, the chemiotactic substances generated at the site of the lesion suffice to draw them from their lurking places in the viscera and throw them into the peripheral circulation, is a subject beyond the scope of this paper. But it is a subject which I think is of importance, since, if we knew more of the place and conditions of the leucocyte's birth, it is possible that we might find ourselves able to influence those conditions in such a way as to excite a leucocytosis at will, an arrangement which might be a valuable therapeutical measure.

If, however, bearing in mind the two factors I have mentioned, we work upon the hypothesis that a leucocytosis is the expression of Nature's effort to counteract the toxæmia, a clear grasp of the general principle will be obtained. In describing the effect on the blood generally, it will be best to take each element in turn. I have not devoted any particular attention to the red cells, or the amount of hæmoglobin. Da Costa, however, who investigated this question, came to the conclusion that in the average acute case there was a loss of half a million red cells and 30 per cent. hæmoglobin. The thickness of the fibrin network is, I believe, generally increased, but I cannot speak on this point from my own observation. The number of blood platelets is also increased; although I never counted them, my impression is that I have seen more of them in cases with a large leucocytosis. The greatest alteration is found in the white cells. The normal number may be taken as 7,500, of which 60 to 75 per cent. are polym., 15 to 30 per cent. lymphocytes, 4 to 8 per cent. hyaline, 1 to 3 per cent. eosinophiles. The great increase of the total number is of course the most prominent feature of the blood picture. Almost equal in importance is the increase of the polymorphonuclear element, and thirdly, the diminution of the eosinophiles and lymphocytes. The hyalines about keep their place. The polymorphonuclears and hyalines are the most active phagocytes in the blood.

It was found, on taking the averages of the acute and of the more or less chronic cases in the table, that the leucocytosis of the twenty-two acute cases averaged 27 990, of which 84·9 per cent. were polymorphonucleous and 0·4 per cent. eosinophiles. Of the fourteen subacute and chronic cases—I take the pathological condition as the basis of classification—the average leucocytosis was 10·614, of which 63·1 per cent. were polymorphonucleous and 2·1 per cent. eosinophiles. The average count of five acute cases after operation, and just before leaving the hospital, was, whites, 10·500; poly., 60·1 per cent.; eosinophiles, 2·5, or a condition almost exactly similar to the chronic cases.

There are certain special factors which have to be taken into consideration. First, the influence of age. An analysis of the twenty-two acute cases gives the following results :—

Age.	No of Cases.	Whites.	Polym.	Eosinophiles.
Up to 20	6	26·100	85·8	0·3
20—30	8	24·320	83·9	0·35
30—40	5	39·610	86·8	0·32
Over 40	3	21·160	80·8	0·8

The number of cases is, of course, too small for these results to be of much value, but so far as it goes the table shows that leucocytosis is most free between the ages of 30-40, and diminishes after 40.

The physiological influence of age on leucocytosis is marked in the early months of life. At birth the number averages 18,000, sinks to 12,000 at the sixth month, and reaches the normal about the fifth year. The normal percentage of polymorphonuclears in infants is from 28 to 40 per cent. Marked leucocytosis also accompanies the later stages of pregnancy. An increase of 2,000 to 3,000 leucocytes may occur after a large meal or exercise in a healthy adult.

Reference must be made to cases where there is little or no leucocytosis, although the lesion is severe. First, there is a class of case in which the toxæmia is so intense that the reaction of the patient is overwhelmed. This class of case must, I think, be rare. Case 15 may, perhaps, be regarded as an example, as the lesion was very acute and extensive, and the patient a pale, ill-nourished boy, æt. 9. Secondly, a thick wall of inflammatory material surrounding a collection of pus may prevent the escape of the toxins which in some way cause the increase in the leucocytes. But in these cases valuable information may be gained from the differential count, a high percentage of polymorphonuclears indicating the possible severity of the lesion. Case 19 is a good example of this. The leucocytosis was only 14,000 on admission, but 83 per cent. were polymorphonuclear. The count sank to 8,600 in two days, but on operation a small thick-walled abscess was discovered. In Case 31, however, where the blood picture was much the same, no pus was discovered, but the parts were the seat of considerable recent inflammation.

Other cases which I might refer to are Cases 8 and 13. In the former, a spare man, æt. 51, the leucocytosis never rose above 11,500, and yet, although there was no pus, there was most extensive ulceration of the appendix. The clinical symptoms seemed to accord with the result of the blood examination.

Case 13 is interesting. The girl came in, in no very serious condition from the clinical point of view. The leucocytosis was 25,000 with 85 per cent. polymorphonuclear, next day it was 27,300, and on operation a long and gangrenous appendix was removed. The temperature fell, the wound healed, the bowels were open, no pain was felt. The clinical picture was in all respects highly satisfactory. Yet nearly a week after the operation the leucocytosis was 29,250. The evacuation of a deep collection of pus a few days later explained this apparent anomaly. Perhaps Case 25 may be noticed as an example of the influence of age.

There are a few interesting points in the second table. In Case 1 the somewhat high eosinophile count was probably caused by the presence of worms. In the first six cases, which were tuberculous in character, the number of lymphocytes is rather high. Cases 7 and 8 are high in eosinophiles, which is said to be the distinguishing feature of the blood in hydatid cases.

Case 9 is particularly interesting. The man was seized with sudden abdominal pain about half-past one. He came in in a very collapsed state, and remained so for three hours ; he then vomited slightly twice, and there was a streak of blood in the vomit. The pulse rose from 80 to 100. The abdomen was rigid, but not tender, and there was some diminution in the hepatic dulness. At 6.30 reaction began to set in. At 7.30 I counted his blood, but unfortunately omitted to make any films. There was, however, a leucocytosis of 22,950. The abdomen was opened at 9·15, and free fluid and a little gas found. There was no lymph, but the peritoneum was injected. A perforation of the stomach was found. The interest of this case is the fact that the leucocytosis occurred with such rapidity.

In conclusion, I must express my indebtedness to the medical and surgical staff of St. George's Hospital for their kindness in placing their clinical material at my disposal. I hope that the accompanying table will serve as an illustration of the value and the shortcomings of blood examinations in abdominal diseases. And, if I may be allowed to express an opinion, I think that we cannot regard a leucocytosis as an absolute and infallible indication of the presence of *pus*, but as an indication of toxæmia its value appears to me very great. Although I do not think it possible at present to fix any definite relationship between the amount of the leucocytosis and the intensity of the toxæmia, yet the broad fact remains that an increasing leucocytosis is, other things being equal, the most scientific means at our disposal for gauging the increasing virulence of an appendicular infection. On the other hand, a decreasing leucocytosis is evidence of decreasing virulence or walling-off of the toxic products.

I cannot do better than sum up the practical moral in the words of Da Costa :—"The surgeon who attempts to use the blood count in appendicitis as a definite pathognomonic sign, will soon run afoul of diagnostic disasters, but he who regards it as only a symptom invariably to be correlated with other equally, if not more, important clinical manifestations, cannot fail to find this method of inquiry of signal value in routine clinical surgery."

Sudden and Accidental Deaths.

An inquest was held last week in respect of the death of Dr. James Rodger, of Caledonian Road, N. The deceased had for some years suffered from symptoms of cardiac angina, and after an effort he suddenly expired. A verdict of death from syncope was returned. More tragic was the death of Dr. H. W. Pepper, of Birmingham, who was knocked overboard by the boom while yachting on the river Bure, and, having probably been rendered unconscious, was drowned before assistance could be rendered. His companion, a Mr. McDougal, was saved.

THE DIAGNOSIS, PREVENTION, AND TREATMENT OF PUERPERAL INFECTION. (a)

By FREDERICK HOLME WIGGIN, M.D.,

Visiting Gynæcologist City Hospital, and Visiting Surgeon at Elizabeth's Hospital, New York; Member American Medical Association; the New York Medical Association; Fellow New York Academy of Medicine, &c.

Thomas Kirkland, Ashby, England, in 1774 called attention to the fact that the so-called puerperal fever was a contagious disease. This view was later supported by other independent observers, notably in 1843 by our own Oliver Wendell Holmes, by Sir James Young Simpson in 1846, by Semmelweiss in 1847, and by Trousseau in 1858. But it needed the teaching and practical results obtained by Lister, based on the previous work of Pasteur and by the demonstration of the latter in 1880, that streptococci are often found in the lochial discharges of puerperal women suffering from fever and other constitutional disturbances, before obstetric surgeons finally recognised it as a fact that these pathological manifestations were due to the same micro-organisms, whose entrance into wounds in other parts of the body were followed by similar constitutional disturbances, and that when the wounded maternal parts were kept free from these organisms or their products: that the puerperal woman during her convalescence was free from constitutional disturbances of a febrile nature. The practical result of the acceptance of these views and the change in technique in obstetric practice which followed in lying-in hospitals resulted, as is well known, in the practical abolition of epidemics of what was formerly known as puerperal fever, with its high mortality rate; till at the present time, when infection of the mother's wounds does occasionally occur, the constitutional symptoms are mild in character, the disease is readily controlled, and the mortality rate a fraction of 1 per cent. Unfortunately these results have not been achieved by all physicians in private practice, and it seems strange that we are obliged to admit that puerperal wound infection in the ordinary daily practice of physicians, is probably almost of as frequent occurrence and is followed by as severe constitutional symptoms and with as high a rate of mortality as it was fifty years ago. Many physicians have been slow to grasp the importance of the principles underlying modern surgical teaching, or while knowing these principles they have yet failed to apply them to obstetric work and consequently have not profited by them. They are still too often seeking consolation and explanation of the fever and other constitutional symptoms complicating the puerperal convalescence, in the possibility that the disturbance arises from the beginning of lactation, or from the specific poisons causing malarial or typhoid fever, instead of attributing those symptoms to their true cause, in almost every instance, wound infection.

Before considering the diagnosis of abnormal puerperal conditions, it is well to recall the fact that when normal conditions prevail during the puerperium, the pulse rate falls soon after delivery and is slower for a time than usual; that the respirations are normal and that there is little or no rise of body temperature; that increase of pulse rate and of body temperature due to emotional causes rapidly subsides, and that similar variations due to an overloaded colon disappear as soon as the bowels move. We should be on our guard, therefore, to quickly recognise that infection of some portion of the wounded maternal parts has almost certainly occurred whenever we find that a puerperal woman during the early days of her convalescence has a pulse-rate of 90 beats a minute or higher, accompanied by a temperature of 100·5° F. or more, especially if these symptoms continue for more than twelve hours. A careful general examination of the patient should at once be made to exclude inflammatory conditions of the breasts and other sources of error; this should be followed by a local examination, and it will probably be found that there are some ulcerating wounds on either perineum, vulva, vaginal walls or cervix, which are covered with a dirty yellowish secretion. If the patient does well for several days and then complains of headache and general discomfort, having at the same time a rapidly rising pulse-rate, a chill, a marked elevation of body temperature, and pains in the lower abdomen, and if on local examination an enlarged doughy and tender uterus be found, with its cervix patulous and the lochial discharge purulent in character, with less colour than usual, it is reasonably certain that the trouble is due to the most common variety of puerperal infection, endometritis caused by the absorption of the products of decomposition, and that on examining the interior of the uterus a retained portion of the membrane will be found; or there will be discovered a roughening of its inner surface at the placental site caused by adherent portions of the placenta. When the trouble is confined to this region, the course of the disease is limited, and in a few days the constitutional symptoms will subside and the disorder becomes chronic; or the entire endometrium may become involved in the process, in which case the condition is more serious, the constitutional symptoms more marked, the lochial discharge having more odour and less colour than in the milder form of the disease. As a rule the trouble does not extend beyond the endometrium, but, when it does, the evidences of its extension are repeated chills and a daily variation of several degrees of temperature, the usual symptoms of pus formation, the rise of temperature continuing until the abscess is opened and evacuated. The peritonitis following this form of the disease is usually circumscribed. A bacteriological examination of the uterine secretions will probably demonstrate the presence of staphylococci, and establish the fact that the disorder is due to their special action. When the cause of the septic trouble is due to the direct invasion of the tissues by the streptococci the constitutional symptoms are much more severe in character; the very rapid and weak pulse especially attracts attention, while on the other hand the local symptoms are less marked in character: the uterus on examination is found less sensitive to pressure, of proper size, the cervix is closed, and the lochial discharge diminished in quantity or absent, or free from both odour and colour. Symptoms of general suppurative peritonitis may be the first local sign of the infection to attract attention. The symptoms of this serious complication usually manifest themselves between the second and seventh days of the puerperium, and are characterised, in addition to the ones already mentioned, by intense pain, which, at first, is limited to the lower abdomen, but which gradually extends upward and is accompanied by tympanites. Septicæmia, the most fatal form of wound infection, results from the direct invasion of the tissues by virulent streptococci and the absorption at the same time by the tissues of the toxines of decomposition produced by the presence of staphylococci. Its characteristic sign is the great amount of bodily prostration which accompanies the other constitutional symptoms of wound infection. Pyæmia manifests itself by the occurrence, ordinarily in the second week of the convalescence, of recurring chills accompanied by a widely fluctuating temperature and the formation of abscesses in various parts of the body. Broncho-pneumonia is a more or less frequent consequence. Phlegmasia alba dolens manifests itself in the second week of the puerperium by pain along the course of one or other of the femoral veins, usually the left, accompanied by swelling of the limb from above downward. When the infection arises from the invasion of the wounded tissues by gonococci, it may usually be determined by the coincident occurrence of ophthalmia neonatorum. The presence of the Klebs-Loeffler bacilli in the wound may be determined by the appearance of the characteristic membrane on the wounded surfaces combined with the usual constitutional symptoms, confirmed by a bacteriological examination of the lochial discharge.

The patient's wounds may also be infected by the bacilli coli communis, the pneumococcus, and others. It is important, as soon as we are aware of the fact that the patient's wounds have become contaminated, that a bacteriological examination, when practical, be made of the lochial discharge, as the information derived therefrom will aid us in deciding the form of treatment to be carried out. Malarial infection can be excluded, as a rule, by remembering the fact that in septic poisoning the pulse-rate is higher than the temperature, and by the absence in the blood of Lavaran's bodies, whereas in malarial infection they are present and the temperature is higher than the pulse-rate.

(a) Read before the New York County Medical Association, and inserted by request.

Typhoid fever may be excluded by the absence of the characteristic eruption and the negative result of Widal's reaction.

The causes of puerperal wound infection having been proved to be the result of the introduction into the parturient canal of septic material either before, at the time of, or subsequent to delivery, the great responsibility therefore devolves upon the obstetric surgeon of preventing its occurrence, which can ordinarily be done by his bearing in mind a few easily-comprehended principles, by the exercise of watchfulness, and by attention to a few simple details, which are easily carried out even in the homes of the poor. It should be constantly borne in mind by the physician that these germs may be brought in contact with the parts by the act of copulation, by the hands of the patient, nurse, or physician, especially if wounds exist in the canal, or by means of unsterilised instruments, syringes used for both enemas and vaginal douches, dirty bedding, linen and towels, neglect to properly care for the patient's body, and to empty the intestinal canal.

The nurse selected to attend an obstetric case should be chosen with as much care, if practicable, as one would be for a patient on whom an abdominal operation is to be performed, or, in other words, she should understand the prime importance of cleanliness, and be sufficiently trained to carry out the necessary details, as well as to be able to care for the infant; it is as well when possible to have the nurse in attendance on the patient a short time before the expected delivery, and the necessary instructions should be given to her to empty the patient's bowels and to get her skin in good order by means of hot baths, especially that of the external genitals and the anal region, before the expected delivery. At the first indication of labour the rectum should be washed out by an enema of soap suds, and as soon as this has been accomplished the mother should be given a final hot bath, after which the genitals and the anus should be washed with a solution of carbolic acid and the parts protected by a sterilised napkin—or what is better, an obstetric pad—until the end of the second stage of labour has been nearly reached; after this preparation each act of urination or defæcation should be followed by again thoroughly cleansing the external genitals and the anal region, by washing them thoroughly with an antiseptic solution.

The physician on his arrival should be careful to disinfect his hands before making a vaginal examination, and this he can readily do by scrubbing his hands and arms in hot running water, preferably using tincture of green soap, and scrubbing them for ten minutes with a fibre brush. The hands should next be immersed in alcohol, the nails being cleansed with a piece of sterilised gauze wet in the alcohol; they should next be immersed in an alcoholic solution of bichloride of mercury of the strength of 1-500, which solution should be removed from the hands by sterilised water before the lubricant is applied to them, which lubricant should be contained in a collapsible tube, or the physician after cleansing his hands may put on rubber gloves that have been boiled for at least half an hour and have then been soaked in a 1 per cent. solution of lysol. As few vaginal examinations should be made as possible during labour, the required information, after the position of the child has been determined, can be obtained by external examination, with the exception of that relating to the duration of labour. As the second stage of labour draws to a termination the obstetric pad should be removed, the patient placed on a sterilised sheet, and her thighs and abdomen protected with sterilised towels, or with those which at least have been recently washed, and the obstetrician should wear a gown or an improvised one made from a sterilised sheet.

It is, of course, of the utmost importance that the membrane and placenta should be removed intact; the physician should make certain of this by carefully inspecting them after they have come away, and if he finds that portions of either have been retained he should, after thoroughly sterilising the external genitals, the vagina, and his hand and arm, determine this by an intra-uterine examination, removing them if found; this procedure should be followed by an irrigation of the uterine cavity with sterile salt solution followed by hydrozone. This complication will, however, seldom occur if the physician abstains from administering ergot to his patient until after the delivery of the placenta.

As soon as the labour is over and the patient has had time for a little rest, the physician should make a careful inspection of the perineum, vulva, vaginal and cervical tissues, and if any lacerations of the parts are found they should be at once repaired and the parts washed with sterile salt solution and hydrogen peroxide, and protected with sterilised pads. No intra-uterine douche should be given unless it has been necessary to introduce the hand into the uterine cavity. In the after treatment of the patient under normal conditions, vaginal douches should be omitted, the nurse being directed to keep the external genitals and the anal region in good order by carefully washing and disinfecting them after each act of urination and defæcation.

If, on visiting the patient the physician finds an accelerated pulse and elevated temperature, he should carefully examine her, and afterwards make a local examination, first disinfecting his hands and instruments. If he finds an ulceration of the perineum, vagina or cervical tissues, he should thoroughly wash out the vagina with salt solution and follow this with hydrozone or other strong solution of peroxide of hydrogen. If, in the judgment of the physician it is necessary to follow this treatment with other irrigations of the vagina, he should administer them himself and not leave them for the nurse. If the septic trouble is more serious in character, and is due to the retention in the uterine cavity of decomposed septic material, the patient should be put on a table and placed under the influence of an anæsthetic, and after the external genitals and vagina have been carefully disinfected the uterine cavity should be explored with the finger, which has also been carefully disinfected—or if the operator is trained and skilful with the curette—and the offending material removed. The cavity of the organ should then be thoroughly washed out with saline solution followed by hydrogen dioxide and an application of Monsell's solution if the cavity has been curetted. If the operation has been well performed the patient's constitutional symptoms will probably disappear and no further uterine intervention will be necessary. It will, however, probably be best for the physician to give the patient a vaginal douche of saline solution, followed by hydrogen dioxide once or twice a day for several days. If, however, the constitutional symptoms persist and the condition becomes chronic, it may be necessary to again explore the cavity of the uterus. If the trouble extends beyond the endometrium and an abscess forms, it should be evacuated by means of a vaginal incision, or if there be a bilateral pyosalpinx to deal with, it may be necessary to open the abdomen and remove the diseased tubes and uterus. If it be determined after careful examination that the septic condition of the patient is due to the direct invasion of the tissues by the virulent streptococcus, the physician should, in the writer's opinion, after thoroughly cleansing the external genitals and the vagina of the patient, dilate the cervix and explore the uterine cavity with the finger or with the curette, and then after thoroughly irrigating the cavity with saline solution and hydrozone, should make an application of Monsell's solution. If the constitutional symptoms of the patient as the result of treatment do not show improvement in a few hours, an intravenous infusion of a considerable quantity of saline solution should be given, and the advisability of opening the abdomen and removing the uterus considered;

bearing in mind, as has been pointed out by Vineberg, that the uterus is the focus of the disease and that the patient's system will eliminate a reasonable amount of infective material by the skin, kidneys, and intestines; therefore, if the further production of the poison can be stopped, there is a reasonable chance of that already in the patient's system being eliminated and recovery following.

Although a few observers have claimed benefit to have accrued to their patients suffering from this form of infection from the use of Mamorek's anti-streptococcus serum, the burden of testimony is against its having been of any avail in these cases; if used, from 10 to 20 cubic centimetres should be injected into the patient's body every twelve hours till she shows signs of improvement, or a reasonable quantity has been used. When, from the severe prostration and other constitutional symptoms which accompany it, there is reason to believe that the patient is suffering from septicæmia, she should at once be stimulated and given the benefit of a large intravenous saline infusion slowly administered, the temperature of the solution in the reservoir being 120° F., and if she rallies in response to this treatment the vagina and uterine cavity should be cleaned out by thoroughly washing them with saline solution followed by hydrogen dioxide, and the cavities loosely packed with sterilised gauze soaked in ozonised glycerine, which will tend still further to disinfect the parts; the gauze should be removed in from eight to twelve hours, and the application repeated. If under this treatment there are signs of improvement, it may be continued at lengthening intervals, or the propriety of more radical measures be considered. If there is no improvement in the patient's condition, further operative treatment will be of no avail. If pyæmic conditions are recognised before the onset of pneumonia, there may be some hope under favourable conditions of saving the patient by cleansing and disinfecting the external genitals and vagina, followed by the prompt performance of an abdominal hysterectomy. When thrombosis of the femoral vein occurs its course should be painted with iodine, the limb wrapped in cotton, bandaged, and kept in an elevated position, which should be maintained for two weeks after all swelling has disappeared. Abscesses should be promptly opened.

In the treatment of the various forms of puerperal wound infection there is little to be hoped for in the use of drugs except as temporary aids, the physician's reliance being placed rather on the administration of proper nourishment, increasing the activity of the skin, the kidneys, and the bowels by the internal administration of large quantities of saline solution by means of enemas, injections under the skin or into the patient's veins, according to the urgency of the symptoms, and appropriate carefully considered local treatment, which must be decided for each case as it arises.

Curettage and other operative measures should not be universally condemned because when performed by inexperienced and untrained men, or under unfavourable conditions, they have more often been followed by harmful rather than good results. The importance of an early recognition of the fact that the patient's wounds have become infected cannot be overestimated, for on this the physician must rely to institute proper local treatment at an early stage of the trouble, and before the patient's system is overwhelmed by the poison, for on this must largely depend whether or not the prognosis of the graver forms of the disorder is to be more favourable in the future than in the past.

Who Shall Decide?

The Ballachulish (N.B.) Quarries Co. recently decided to dismiss their medical officer, a step which was resented by the workpeople, who have made strong representations to the Company in opposition thereto. Failing satisfaction they have requested the medical officer to continue his ministrations, and they threaten to strike if any obstacle be placed in his way. This incident is a refreshing contrast to the conflicts which have been waging of late between working-men and their medical officers in respect of increased emoluments.

SOME SUGGESTED STANDARDS FOR PHARMACOPŒIAL PREPARATIONS. (a)

By J. C. McWALTER, M.A., D.P.H., F.F.P.&S.Glasg.

John Stuart Mill, in a passage which has greatly influenced the trend of thought among his followers, denies that medicine can be regarded as a science. It lacks, he argues, that correlation between cause and effect, that invariable sequence between antecedent and consequent, which elevates a branch of learning to the dignity of a science. In Mill's time medicine meant therapeutics, and it is to this department that the reproach may still be levelled with much justice.

All things which can be reduced to units of mass length and time may be the subjects of a science; and the object of standardisation of drugs is obviously to reduce them to definite active factors. Drugs vary in their action with different individuals, and even with the same individual at different times; but until we know that we are dealing with the same amount of active principle it is impossible to allege that the variation is due to some alteration in the drug, and not to some idiosyncrasy in the individual.

Climate, season, soil, and sun modify the amount of active constituents in a given drug, and the element of uncertainty of action caused thereby may be reduced by the expedient of standardisation. Notwithstanding its utility it is but a temporary expediency, and when we arrive at more certainty as to the source of action of each drug standardisation will naturally cease; for as soon as we know, and can isolate commercially, some active principle, whether resinoid, glucosidic, alkaloidal, oily, acid, or ferment, its galenical preparations must gradually pass away and be displaced by the chemically separated active principles. The articles in the Pharmacopœia already standardised, as nux vomica, cinchona, belladonna, ipecac, &c., have given great satisfaction to therapeutists. The effects of the drugs have been studied with an accuracy which bids fair to redeem pharmacology from reproach, and to restore scientific therapy to its proper position. But much remains to be done in the direction of standardisation of a humbler type, that, namely, wherein a given weight of extract is directed to be obtained from any sufficient quantity of a drug, of which the liquid extract of poreira is the type in the present Pharmacopœia. Hitherto the pharmacist has been directed to take a given weight of drug and produce from it an indefinite weight of extract, of a varying consistency known as "pilular," whereas now we have advanced a step by requiring him to produce a definite weight of extract from as much of the drug as may be needful. Thus to some approximate extent we guard ourselves against variations in the strength of the green root, fruit, leaf, seed, &c., which may be due to season, soil, temperature, &c. Of the more important drugs capable of definite standardisation some may be mentioned. The alkaloidal strength of coca extracts varies notoriously, and most of all the so-called soluble varieties used for coca wine making; commercial extracts vary in strength of total alkaloid from ·182 to ·613 per cent. The bulk of fairly well made ones reach about ·4 per cent., and this would be a reasonable standard. One-half per cent. has been suggested, but there is a danger in encouraging too potent an article as a drug for popular consumption, and a limit of about ·35 to ·40 per cent. would be fair. Jaborandi will never obtain that honourable place in therapeutics which pilocarpine has been granted unless a system of standardisation be adopted. The proportion of the latter is usually estimated at 1 in 200, and hence ·5 per cent. would seem a proper percentage. On the other hand, if this limit were adopted, as Merck has pointed out, makers would stuff their extracts with a sufficiency of that alkaloid to pass the test; whilst jaborine and pilocarpidine might be wanting. A total alkaloid yield of one-half per cent. would then probably be preferable.

Belladonna.—The fluid extract and tincture are now so satisfactorily standardised that many practitioners have been rather alarmed at their activity. It remains to standardise the green extract, and 1 per cent. of alkaloid separated and weighed is generally advised.

(a) Paper read before the British Medical Association, Manchester, July 30th, 1902.

Ammoniacum.—Only that with an essential oil and of strong odour should be used in pharmacy. To ensure this a limit of insolubility in 90 per cent. alcohol should be laid down, perhaps 20 per cent.

Anisi Fructus.—Much of the seeds and fruits of commerce is contaminated with dirt, and to restrain this within reasonable limits an ash limit ought to be stated, certainly not more than 10 per cent.

Araroba is a drug decidedly useful, which has got into disrepute through samples being so largely adulterated: an exact ash limit should be mentioned—probably 20 per cent.

Calumba.—This also requires an ash limit, say 7 per cent.

Cantharis.—There is no living medical man but has been at some disappointment in the action of a fly blister or other preparation of cantharides. This would be largely overcome if preparations were standardised as to cantharidin, according to the method of Greenish and Wilson. Any varieties of blistering beetle could then be used if they yielded, say, ·5 per cent. of cantharidine (1 in 200).

Cascarilla was at one time somewhat prized as an aromatic adjunct of more potent remedies for skin and stomach affections; that it should be condemned as untrustworthy is not wonderful, seeing that the proportion of extractive varies from 5 to 14 per cent., and the ash from 8 to 24 per cent.; probably, if a limit were fixed of 8 per cent. of extractive and 10 of ash, pharmacologists might again become reconciled to its use.

Digitalis.—There is scarcely a drug of more vital importance than digitalis, and every effort should be made to have it of uniform strength. Hence the official directions as to the growth of collections of digitalis leaves are justifiable, although digitoxin is possibly not the active principle, and probably not the sole active principle; but its proportion is a good guide for standardisation. It has been shown to vary from ·533 in June to ·381 in August, diminishing till scarcely a trace is left. Hence, if a minimum of ·5 per cent. of crude digitoxin were officially required, with not more than 8 per cent. of ash, an approach to uniformity would be acquired.

Cascara Sagrada.—Practitioners have found this drug to vary very much in effects, which is no wonder when commercial specimens of the fluid extract yield from 15 to 30 per cent. of extractive. As it tends to deposit the limit of solid extract, yield by it should not be too rigidly fixed, but 24 per cent. would be a satisfactory amount, which ought to be insisted on.

Extractum Ergotæ.—Some indication of potency is urgently required. Until a satisfactory assay process may be devised, fluid extracts prepared according to the official modes should be made to yield 20 per cent. of extractive when dried to 212° F.

Extractum Taraxaci Liquidum.—This preparation, as found in the pharmacies, is notoriously variable. A gravimetrive method ought to be adopted showing 25 per cent. of residue per fluid ounce.

Ferri Sulphas Exsiccat.—The B.P. standard for this, 92·5 per cent., is somewhat too high. Commercial standards average about 90 per cent., and the lower figure is preferable, as when too high a per centage is sought for the salt is rendered insoluble and partly inert.

Fœniculi Fructus.—Not more than 9 per cent. of ash should be present.

Galbanum.—Not more than 50 per cent. ought to be insoluble in 90 per cent. alcohol, and the ash yield should not exceed 10 per cent.

Guaiaci Resina.—To detect colophony or other adulterations acid numbers should be given. The crude lump 90 to 95, natural tears 70 to 75, &c, and an ash limit of not over 1 per cent. are fair figures.

Infusa.—The infusion is generally looked on as a method of preparing medicines only fit for a housewife. There has been no appreciable improvement in their method of making for the last century, except in a couple of instances, as cinchona and roses. They are notoriously variable in their strength, and untrustworthy in their action, whilst the different colours which they show when prepared by different chemists are a constant source of trial to nervous patients and annoyance to harassed physicians. If figures were laid down for the amount of extraction some approach to uniformity would be obtained. Gadd, a maker, gives the following as fair averages:—

	Per cent. extraction.
Infusion of orange	1·43
Infusion of calumba	0·54
Infusion of cascarilla	0·27
Infusion of cloves	0·59
Infusion of buchu	1·25
Infusion of digitalis	0·28
Infusion of serpentary	1·38
Comp. infusion of gentian ...	1·02
Infusion of senega	0·88
Acid infusion of roses	0·73

Pulvis Glycyrrhizæ Compositus.—This article has now become so popular a remedy, and is turned out in such large quantities and under such competitive conditions, that a test is required for an article strictly conforming to the B.P. directions. The moisture should be 4 to 6 per cent. ash, not above 5, and soluble ash not exceeding 3 per cent. Not less than 4 per cent. should be yielded to 70 per cent. alcohol

Liquores Concentrali.—The concentrated liquors of the present Pharmacopœia are a great advance of the concentrated infusions of the shops. They would be still more satisfactory if a definite strength of extractive were directed for each, as those now sent out vary with the strength of every maker's press, as well as the character of the crude drug. Thus calumba should give 4 per cent. of extractive, senega and rhubarb 10, gentian the same. Other concentrated liquors might well be added, as cinchonin, cinchona, digitalis, serpentary, uvæ ursa, &c.

Oleum Caryophylli.—The specific gravity test is scarcely sufficient as a criterion of the purity of this oil. There ought to be added a requirement that it shall yield not less than 80 per cent. to 10 per cent. potash solution.

Tincturæ.—As regards tinctures much is to be said for and against the recognition of a definite specificity, gravity or proportion of total extractives. But where a comparatively definite substance can be recognised its proportion ought to be insisted on as of aloes, which should show 7 per cent. and asafœtida 10 per cent. Colchicum should be standardised to ·075 per cent. of colchicine, and conium to ·1 of total alkaloids.

Cubebs should yield 2 per cent. of oleo, resin, and gelsemium ·025 per cent. of gelsemine, hyoscyamus ought to be of a uniform strength of ·01 of total alkaloid per cent., jaborandi of ·05 pilocarpine.

Lobelia has sunk in the estimation of physicians on account of its untrustworthiness. It would recover its reputation if it were standardised to ·075 of lobeline.

Myrrh should yield 6 per cent. of resins, and squills 10 per cent. of total solids.

Stramonium ought to give not less than ·05 of total alkaloid and strophanthus ·3 per cent. of strophanthine.

Tolu should be standardised to 2 per cent. of benzoic and cinnamic acids.

Special Article.

PRIMITIVE, PRE-HISTORIC TREPHINING.

The exceptional interest attached to the operation of trephining is partly due to the fact that this method of surgical procedure deals especially with the environments of the organ of thought—the healthy functions of which furnish the elevating factor that assures to man the distinctive position of "Lord of the Creation"; partly, to the thrilling feeling of danger which was connected with its performance before the introduction of antisepsis; and partly to the hopeless uncertainty regarding its applicability in cases other than depressed fracture, which continuously hovered over the mind of the surgeon before the brilliant dawn of "cerebral localisation." The possibilities of latter-day trephining hardly require critical discussion in the opening years of the twentieth century; but the archæology of the procedure has, from time to time, of recent years thrown some twinkling rays into the dark recesses of pre-historic surgery. The interest attached to the consequent revelations has been further emphasised by the recent discoveries which have demonstrated the preservation of those old-time methods of primitive man in search of relief from physical suffering, in the remote corners of the world whose inhabitants have hitherto escaped the enlightenment, or the contamination, of the habits and results of modern civilised life. This attractive subject of pre-historic trephining has attracted a good deal of attention from archæologists and surgeons, more especially since the lead in that direction was taken by the illustrious bearer of the name of Paul Broca—the brilliant and many-sided professor of medicine, the thoughtful and conscientious French senator, and the keenly-scrutinising archæologist. Prominent and permanent landmarks have since been raised along the same scientific route by Prunèires, Paris, Chouquet, Gassie, Wankel, Virchow, and other distinguished investigators. And, in the recently issued number of the *Journal of the Anthropological Institute of Great Britain and Ireland* (July to December, 1901), we find a most interesting communication on this subject which hails from the far-away "South Seas," to the trephining practices of whose island inhabitants M. Broca himself called attention a good many years ago. The author of this interesting and instructive contribution to our knowledge of the subject of primitive methods of trephining is the Rev. J. A. Crump. He has well and profitably utilised the spare hours which his clerical duties have left on his hands by collecting important material for the enlightenment of his scientific brethren and friends in the old countries. We congratulate him, as well as the members of the Anthropological Institute—and ourselves—on the fact that his paper and specimens were submitted by Mr. (now Sir) Victor Horsley, who has devoted so large a share of the best energies of his professional life to the advancement of our knowledge of cerebral localisation, and of the applicability of the surgical procedures connected therewith. In his original communication on the subject, M. Broca told his readers that "until quite recently trephining of a primitive kind was in use among some of the South Sea Islanders for the treatment of epilepsy, insanity and even headache, and the operation was done by scraping with a piece of flint or broken glass, when the latter was to be had from Europeans. In much the same way, and with similar instruments, the operation was done in the neolithic or polished stone period, the age following the so-called quaternary, and preceding the bronze epoch. This period corresponds with the burial in dolmens, the use of agriculture and the employment of domestic animals, the making of hatchets of polished flint, though rough chipped instruments were still in use." The scrutiny of the skulls which were examined by Broca and Prunèires in this connection displayed to them that there had been a practice of post-mortem, as well as of ante-mortem, trephining among those primitive islanders. It also appeared that the ante-mortem—surgical—operation had, in nearly all their specimens been performed in the first few years of life. And—that the posthumous operation had been performed only on those who had undergone and survived the other. In many of the skulls which bore unmistakable evidence of subsequent development it was found that a number of pieces of bone had been artificially chipped off from the margins of the orifice. Some of these detached pieces were actually found, which had been shaped as amulets, or perforated for purpose of suspension. M. Broca's hypothesis of the existence of these facts seems to have been borne out by all subsequent discoveries, and they are largely corroborated by the paper now before us. His explanation was found by referring to the primitive notion that very pronounced head symptoms—such as insanity, epilepsy, melancholy, and even violent headache—were due to demoniacal possession; that the artificial cranial orifice was made to promote the exit o the evil spirit; and—that for the remainder of life the individual would be regarded as a sacred personality, with the superadded distinction that his relics after death would be greedily sought as "charms" and miraculous agents for the warding off or the expulsion of evil spirits. The evidence of such beliefs was further complicated by the fact that in all the cases of this post-mortem trephining noted by those distinguished observers, a certain proportion—usually about one-fourth—of the circumference of the original opening had been left undisturbed; and that the vacancies left by the removal of the amulet material had been, in each specimen, approximately filled by similar pieces from some other skull. In discussing this very curious point M. Broca expands his hypothesis by offering the fact as an indication—the earliest that he knew of—of a belief in an existence after death. It proves, to his mind, that those primitive trephiners believed that the "individuality" was maintained after the death of the body; in religious deference to which faith they would not rob him "in the other life of the glorious evidence of the operation which he had undergone in his youth."

But another feature of perhaps even more inexplicable interest is offered by the fact that the great majority of the trephine holes found in the skulls which had been the subjects of prehistoric surgery were placed in the parietal region—over Ferrier's motor area. Since the attention of medical men (and of antiquarians) was directed to this subject by Broca, a large number of cranial specimens have been discovered and described which bear evidence of primitive operative interference of a similar character. Most of the reports are referred to in a neat little monograph on trephining, published by Dr. J. F. Horne in 1894. Many such skulls were found in the famous cavern of L'Homme Mort in La Lozier. Some were discovered in the grottos of Baye. M. Prunèires found, in 1868, in a large dolmen near Aiquiens, a skull, of which a large portion of one side had been removed. M. Chouquet discovered in a mound near Ecuelles, specimens of both ante-mortem and post-mortem trephining. In 1875 a trephined skull was found in a tumulus at Bougon, near Niort, in the South of France. In the cloisters of Guérin, on the Seine, not far from Paris, the skull of an old man was found, which presented a completely filled-in trephine aperture. Several neolithic skulls in corresponding condition were found near Bage in 1880. M. Gassie found a trephined skull in a mound at Entre Roche; M. Guigan another at Etang-la-Ville. In 1878 Prunèires found in Beaumes-Chaudes (La Lozier) more than sixty specimens of trephined skulls. An extensively diseased skull was found in a grotto of the neolithic period, which displayed unmistakable evidence of trephining. A few prehistoric specimens of trephining have been found in Germany. The skeleton of a girl of about twelve years old was discovered in the Bytchiskala grotto in Bohemia; the skull had been the seat of an ante-mortem trephining operation. And in the immense ossarium of Beinhaus, at Sedle, in Bohemia, a great number of trephined skulls have been found. Some have been discovered in a Criquoian cave near Ziemerin, in Poland. A skull was taken from a tumulus at Bogdauoff, Russia, in which an unmistakably ante-mortem perforation had been made. In Denmark one was exhumed from a dolmen at Boneby, and another from a dolmen at Nois, in the island of Falster. A number of very choice specimens have been recovered at Rokina, in Algeria. An excellent one was found in a collection of human remains belonging to the stone age, which was discovered in the grotto of Casa da Mouva at Penicher. The first trans-Atlantic specimen placed on record was taken from the Tuca cemetery in the valley of Yucay, Peru. American experts pronounced the specimen to be of, at least, ante-Columbian date; and the skull was forwarded to Broca. The result of his examination was, that we are "authorised to conclude that there existed in Peru—before the European epoch—an advanced form of surgery." Dr. Robert Fletcher, in discussing this subject, observes that "The numerous specimens which have been found in Michigan suggest several inquiries. Many more prehistorically trephined skulls have been found in Michigan than in any other State of the Union."

Illinois and Ohio come next in order in respect to the number of such discoveries. Either these States have made more researches than others, or the valley of the Great Lakes contained a race of people who practised trephining, just as there is now a race in the north of Africa who practise it, while the other populations do not. The Kabyles of North Africa are, by some anthropologists, thought to be the remains of the ancient Phœnicians. They practise trephining as a purely surgical measure. Michigan has fewer mounds than any of the States in the great central basins of the United States. Everywhere these mounds have been opened and studied, and the results have shown very few trephined skulls outside of this region. The openings in all Michigan skulls, and in fact in all American skulls, have been near the vertex. They have rarely shown any evidence of cicatrisation, and for those reasons are generally believed to have been trephined for religious rather than surgical purposes." However this may be, the net result of all this distinguished observer's inquiries has been to lead him to believe "that the valley of the Great Lakes once contained a people who practised surgical trephining." Broca's original suggestion that the pre-historic operation of trephining was performed with the aid of a piece of flint or shell, has been well borne out by subsequent revelations. He presented to the Paris Society of Anthropology some skulls on which he had produced appearances very similar to those presented by the neolithic ones, by scraping with a piece of glass. It has been critically observed that the incisions of the "Inca skull" from Peru appear to have been made with some cutting instrument, "something like an engraver's burin, and not with a saw." Sir Victor Horsley—in connection with Mr. Crump's paper—showed three photographs of American specimens. He regarded the traces as those of saw-cuts. They were all in the frontal region; and, taken in connection with the recent evidence supplied by Mr. Crump, he thinks that the conditions found give "reasonable ground for believing that the Peruvian operation was probably done for headache."

The short paper furnished by Mr. Crump gives some very interesting new facts, and throws explanatory light on some old ones which had previously been obscure. In New Britain, as he had previously reported, the operation of trephining is performed for fracture—only. The instrument used is formed of a piece of shell or a flake of obsidian, and the operator is the wizard or "tena-papait" of the tribe or district. A blow from a sling-stone is usually the cause of the fracture for which the operation is performed, the sling being the most formidable weapon used by the pugnacious natives in their tribal fights—"a smooth stone as large as a pullet's egg being thrown with moderate accuracy but considerable force." It is found that death almost invariably follows in cases where the injury is not promptly treated. "Injury caused by the stone-headed club is almost instantly fatal, but the flat, two-edged club is not so deadly, and permits of an occasional operation. A V-shaped or Y-shaped incision is made over the seat of fracture; and, while assistants hold back the scalp, any loose fragments are picked out with the finger-nail. The other portions involved in the fracture are then scraped, cut and picked away, leaving the brain exposed to the size of half-a-crown. Then, all loose pieces having been removed, the scalp is carefully laid down and the wound bandaged with strips of banana stalk, about four inches wide. These strips are when dry of a spongy nature, the water which formerly filled the cells being replaced by air. Moreover, the inner surface is silky to the touch, and forms an admirable dressing for tender surfaces. It is astringent in its action and non-absorbent, all discharge escaping below the bandage. Sometimes a few bruised leaves are applied before bandaging. The patient is generally insensible from the time of the injury, and, if consciousness returns during the operation, soon faints away again. In five or six days the bandages are renewed, and in two or three weeks a complete recovery is the result. The number of deaths is about 20 per cent., most of these resulting from the first injury, and not from any complication after the operation. Nearly all the deaths take place during or immediately after the operation, and I am assured that if a patient once becomes conscious he never fails to make a good recovery." And the writer has recently discovered that in New Ireland (Neu Mecklenburg) the operation is also performed for the cure (or relief) of epilepsy, and some forms of insanity which are attributed to pressure on the brain. He has in his possession one skull "which has been successfully trephined in no less than five places, the man meeting his death some years after the last operation by a blow from an axe." This man had suffered from severe, local, throbbing headache. Although the cure would not appear to have been forthcoming, the operation was, in each instance, "successful." He reports a case of cure—at least up-to-date—of an epileptic patient by (or following) trephining. On Gerrit Demp Island and in the central part of New Ireland the usual form of operation—often performed for throbbing or beating headache—is in cutting two or three channels down the frontal bone, each of three or four inches in length.

"After trephining has been performed there is frequent partial temporary paralysis which almost invariably passes away, though in a few cases it is permanent. Idiocy is an occasional result also. But the natives affirm that while the cures of insanity and epilepsy are many, the instances where either malady supervenes after the operation are exceedingly few." The writer forwarded three skulls on which the operation had been performed. The first was a sling-stone case, in which the patient died two hours after the operation without having recovered consciousness. The second was also a sling-stone case, in which the damaged portion (of anterior wall of frontal sinus) had been removed, apparently without the use of instruments—seven years before the patient's death. The third specimen was that of a skull in which a gutter operation had been performed in the region of the frontal eminence for the relief of headache. Sir Victor Horsley points out that it was "almost an exaggeration of a linear osteotomy." There was "an opening made of the inner table in a slight degree." In connection with this case, Mr. Crump informs us that "There are many persons in this village [Olotai, in New Ireland] who have been trephined. It has become fashionable, and a handsome girl or boy is generally persuaded to submit to the operation as an aid to longevity, there being no absolute need for its performance." Such is the present state of our knowledge of primitive methods of trephining—whether pre-historic, or (correspondingly primitive) contemporary. And interesting it is to note in this connection, that the utility of obsidian, which, as Mr. Crump tells us, is so usually employed by the South Sea Islanders in this operation has been recognised in Europe since the dawn of the Christian era. It was first specially described under its present appellation by the elder Pliny. The name was given to it from that of Obsidius, who discovered it in Ethiopia. It is really a natural glass, so far as any substance of volcanic origin can be called "natural"; for it is, in fact, a species of lava. *Trephining—natural glass*—is there anything new under the sun?

THE
BRITISH MEDICAL ASSOCIATION
IN
MANCHESTER.

LITERARY PRODUCTS.

The recent Manchester meeting of the British Medical Association has given occasion for the issue of several notable works, which will prove not only of interest in recalling pleasurable memories, but when this year's annual gathering has been long forgotten will be prized and consulted as works having a permanent value.

The first place must be accorded to Professor Sterling's sumptuous volume on "Some Apostles of Physiology," being an account of their lives and labours—labours that have contributed to the advancement of the healing art as well as to the prevention of disease.

The work is dedicated "To Walter Whitehead, President of the British Medical Association, 1902, Consulting Surgeon to the Royal Infirmary, Manchester, late Professor of Clinical Surgery in the Victoria University and the Owens College, whose love of Art and whose liberality have made it possible to issue this volume in a manner worthy of the event it is designed to celebrate. MCMII." It is impossible to praise too highly this very beautiful and. as we venture to think, unique work. The accounts of the lives of many of those who, directly or indirectly have contributed to the advancement of physiology, or to use the old phrase, the "Institutes of Medicine" are full of interest and characterised by high literary merit, but the plates, which are very numerous, are of the highest excellence. The photogravure of "The Queen's John Hunter" is simply superb. The printing, binding, and general get up of the work makes for distinction, and is worthy of Messrs. Waterlow and Sons.

Professor Stirling has been favoured in obtaining the hearty co-operation of many "physiological friends" in the formation of his galaxy of "physiological apostles," but all who are privileged to see this noble work and fortunate enough to possess a copy will not only render congratulations where these are so richly deserved, but will tender loving thanks for bringing into life again the great human forces which have given to physiology its "Apostolic Age." The work has been privately printed, and we have been favoured with a copy through the courtesy and kindness of Mr. Walter Whitehead and Professor Stirling. We venture, however, to express the hope that means will be found to issue a future edition which may be available for physiologists, students and art lovers throughout the world.

"The Handbook and Guide to Manchester," prepared for the recent meeting, and edited by John Howson Ray, F.R.C.S., is of much more than ephemeral interest. It is a series of essays by experts on matters not only of interest to the casual visitor, but likely to prove of service to all who study phases of life in busy centres. Mr. Sutton, the well-known Librarian of the City, deals with the History and Antiquities of Manchester, while Mr. W. A. E. Axon writes on its Political History. A sketch of the physiographical and geological features of the district is given by Professor Boyd Dawkins. The medical officers of health for Manchester and Salford write on the meteorology and health of their charges. Mr. Thomas Hudson details the development of municipal law in the city. Phases of modern Manchester are portrayed by Mr. Charles Sutton. The parks are described by Alderman Birkbeck and Councillor Ward. The libraries of Manchester are pleasant features amidst much that is gloomy. Several articles describe Manchester as a centre of education, Victoria University being dealt with by Professor Withers. In spite of its ugliness Manchester is not devoid of artistic evidences, as Mr. Phythian seeks to show. The commercial and industrial life is also well presented. Professor Stirling describes the work of the medical school. The Owens College is treated of by Dr. Hartog. Dr. Renaud deals with the medical charities of Manchester and Salford. Other features of interest receive due consideration. The book is well illustrated, but lacks a satisfactory map.

"The Evolution of Artificial Mineral Waters," by William Kirkby, F.L.S., Lecturer on Pharmacognosy in the Owens College, was issued by the well-known house of Jewsbury and Brown, of Manchester. It furnishes an admirable account of the initiation and development of the mineral water industry. Detailed technical descriptions of machines and processes have been avoided as much as possible. It is not intended to be a manufacturer's handbook, but a popular account of how artificial mineral waters came into being and how they are manufactured to-day. The work is excellently illustrated, and furnishes much trustworthy information on a subject in which we are all interested.

The Address of the President was a valuable contribution to the local history of medicine. We hope Mr. Walter Whitehead will see fit to reprint it in convenient book form.

Dr. Lloyd Roberts's interesting address on Manchester's early obstetricians and gynæcologists is worthy to be perpetuated in booklet shape.

France.

Paris, August 16th, 1902.

Ligature of the Axillary Vein.

At the meeting of the Société de Chirurgie, M. Dumoulin related a case of rupture of the axillary vein during ablation of a ganglion in this region. A ligature was placed on the wounded vessel, and the patient recovered without presenting any œdema of the arm.

Foreign Body in the Stomach.

M. Cerné communicated the case of a patient who, ten years ago, swallowed a long narrow spoon, and never felt any inconvenience from it. Ultimately, however, gastric disturbance set in, and palpation revealed the presence of a foreign, quite mobile, body in the stomach. A lateral incision was made through the rectus muscle and the spoon removed without difficulty. No obvious lesion was found in the stomach, contrarily to what might have been expected.

Treatment of Vertigo.

For the treatment of vertigo Prof. Vires recommends special and general treatment. The special treatment should be directed to the different causes of vertigo when they can be traced to affections of which vertigo is but one of the symptoms; syphilis, malarial fever, gout, gastric affections, &c.

As regards general treatment he recommends iodide of potassium, ten to twenty grains daily for months, with periods of rest, and quinine as advised by the late Professor Charcot. However, the quinine should only be tried when other methods fail, as it affects hearing, and leads, if prolonged, to absolute deafness. About six or eight two-grain pills should be given daily for a week. During these days the noises in the ears and the vertigo increase considerably, but if the drug is suspended for a similar period, a notable improvement takes place. Given again for eight days, the quinine produces less effect, and a second rest of eight days is followed by a still more marked improvement. Treatment should be continued in this manner until a cure takes place. The vertigo due to arterio-sclerosis should be treated with small doses of iodide of potassium.

Iodide of potassium, ʒj;
Water, ℥x.

Two tablespoonsful daily for three weeks in the month, at the same time three drops of a solution of nitro-glycerine (1-100) might be given morning and evening, and a milk diet be prescribed for eight days every month, while purgatives should be given frequently.

If tachycardia be present, one or two of the following pills should be ordered daily:—

Extract of convallaria, gr. ij;
Sulphate of sparteine, gr. j.

Insomnia is best treated with trional, and œdema of the limbs by theobromine, ten grains four times a day. If in spite of this treatment the œdema persisted and increased, digitalis should alternate every five days with the bromine, and the patient should be placed on milk diet. A purgative of jalap and scammony should be prescribed once a week.

A Case of Antero-posterior Crush of the Thorax

has been made the text for a very interesting and instructive communication to a recent number of the *Gazette des Hopitaux.* A young man, æt. 20, when in a state of intoxication was crushed against the wall by the wheel of a large vehicle. He was brought into hospital in a state of collapse, with a small, intermittent pulse and irregular staccato respiration. Palpation of the thorax revealed the existence of fractures of the third, fourth, and fifth ribs of the right side, at the junction of the anterior and middle thirds; and of the second and third ribs of the left side near the sternum. Thoracic resonance seemed to be exaggerated on the left side. The area of præcordial dulness appeared normal. There was a cardiac bruit, difficult to describe; but the "bruit de moulin"—characteristic of the effusion of blood and air between the pericardium and inner surface of left lung was not discoverable. This pericardial, or pleuro-pericardial effusion ("epanchement") was suspected on account of the disappearance of a bruit, "de crépitation ou de frottement," which had been noticed when the patient was first brought into hospital. The injured man had passed into a state of somnolence; for a moment he seemed to drop into a state of fatal syncope; the respiration appeared to have stopped, the pulse became almost inappreciable, and the whole surface blanched. From the symptoms Dr. Maclaure suspected that a collection of extravasated blood interfered mechanically with the heart's action; and, accordingly, in order to give him the only chance that appeared available, he explored the cavity of the pericardium. This was done by making an incision from the xiphoid cartilage to the umbilicus, through which the left lobe of the liver was drawn downwards, and the stomach pressed downwards and backwards. The movements of the heart were then visible through the diaphragm, which was now incised at a distance of five or six centimetres to the right of the point of cardiac impulse. Great care was requisite in making this incision on account of the movements of the heart. The pericardial cavity was then explored with the finger through the opening. No traces of extravasated blood were found. Air was drawn into the pericardium through the incision when the diaphragm descended, and expelled during the return movement. The first whiff of air so expelled seemed diagnostic of pneumo-pericardium from a communication established by laceration of both serous membranes. The patient sank at 1 a.m. on the following morning, and the autopsy showed that no such communication existed. There were merely patches of congestion and of ecchymosis—with a slight effusion of blood between the adjacent surfaces of pericardium and left pleura. Dr. Maclaure had, in November last, recommended exposure of the heart through a diaphragmatic opening in cases of chloroform accidents—for the purpose of applying massage directly to the failing organ. He believes that there is a future for this procedure of incising the pericardium by "la voie épigastrique extra-péritonéale," which was recommended by Baron Larrey about a century ago.

The International Central Committee of the Crusade against Tuberculosis meets at Berlin on October 22nd.

Germany.

[From our own Correspondent.]

Berlin, August 16th, 1902.

Abnormalities of the Heart.

At the Medical Society Hr. de la Camp showed six children of a family, two boys and four girls, all of whom showed similar abnormalities of the heart. They were more marked in the girls than in the boys. The heart was dilated laterally, and there were systolic murmurs plainly both to be heard and felt. Left of the sternum a band shaped dulness was present, which showed as a distinct shadow under Röntgen illumination. This could be seen to pulsate. Except measles, the children had had no illnesses, and nothing pointed to any past endocarditis. They were more probably cases of retained ductus arteriosus Botalli.

In a previous discussion it had been pointed out that rachitis played a certain *role* in the occurrence of this abnormality; in the case of weakly children the obliteration of the duct was still further delayed by the rachitis. It was further to be observed that both the girls suffered also from epilepsy, the eldest 17 years of age, was also tuberculous, and one of the boys was very backward mentally—almost idiotic. The father of the children died from accident, and whether he had suffered from any cardiac affection was not known; the mother was healthy.

Action of Albuminous Bodies on Blood Clotting.

At the same meeting Hr. Brat introduced this subject. The action of peptones on the blood consisted, as had been long known, in arresting the clotting power of blood; the blood corpuscles fell to the bottom and the plasma remained fluid, and frequently the blood clotted equably or in mass, but without, as in normal blood, any distinct separation into a blood cake. Antipeptone, tryptone, somatose, as the speaker had ascertained, were not in a position to nullify the peptone action. In a similar way to peptone, as further experiments showed, gelatine and gelaton also acted. If gelatine or gelaton delayed the period of blood clotting, it was very questionable whether their employment as hæmostatics by production of thrombi was correct, and whether there was not really a contradiction in their employment for the purpose. In order to determine he made a series of observations.

Biernacki had shown that the sinking of the blood corpuscles was dependent on the fibrine constituent of the plasma; the greater this was the more rapidly the sinking took place. In peptone blood also the fibrine constituent was increased. The falling of the blood corpuscles was not equable, the blood corpuscles rather clustered together in small lumps. This agglutinating property could be called out by adding plasma of the same animal to the blood employed, whilst an addition of serum had not the same effect. From this he had concluded that chemical changes in the blood corpuscles had called forth this phenomenon of agglutination. It had been proved that the presence of globulin and especially fibrinogen increased the agglutination; in peptone or gelatine blood, according to this, the globulin of the plasma must be increased. Alex. Schmidt had shown that cytoglobin, a constituent of the red blood corpuscle, like the fibrinogen of the plasma delayed clotting. From this was explained the contradiction that the bodies named delayed the period of blood clotting and yet were of therapeutic value in the formation of thrombi.

On the living animal, after injury of the intima of the carotid there was a stronger thrombus formation when the animal had been injected than when it had not. After ligature of the vessel without injury to the intima a thrombus formed about the site of ligature only in animals that had been injected.

As the clots after injection of albuminous bodies did not contract, there was a better possibility of their becoming organised from the endothelium of the vessel against which they lay.

At a previous meeting Hr. Krönig introduced the subject of

LUMBAR PUNCTURE IN THE TREATMENT OF PURULENT MENINGEAL EXUDATIONS.

A young man suffering from the spinal form of purulent meningitis had recently been admitted into his department. He had slight headache, but great stiffness of the neck, moderate fever and slowing of pulse, contracted abdomen, &c. By lumbar puncture a pressure of 500 mm. was indicated. The fluid withdrawn was purulent and contained the Jager-Weichselbaum bacillus. Eleven ccm. of fluid were withdrawn and another puncture made a few days later. This time the fluid did not rise in the ascending tube, and not even when aspiration was used. A small quantity of saline solution was now allowed to flow in drop by drop; after a few days pus came; the discharge then stagnated, when some drops were again instilled, and in a short time 6 ccm. had been got in.

After two days another puncture was made, and the exudation was now almost clear, a few pus cells could only be distinguished microscopically, and in another couple of days these also had disappeared, and the patient was now quite well. The speaker believed that the absorption of the pus would not have been possible except for the dilution, and that a chronic meningitis had been prevented by it. Instillation, if carried out carefully, was free from danger, but it could only be useful in the spinal form of meningitis.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 16th, 1902.

CHRONIC NEPHRITIS, PERICORDIAL ADHESIONS, ETC.

AT the "Verein Deutscher Aerzte," Liebscher showed preparations of the liver, spleen and cardia from a young woman, æt. 26, who had died after three months' illness.

About a year ago she suffered from a heart affection, and the diagnosis of her condition comprised mitral insufficiency, chronic nephritis, pericardial adhesions, chronic localised peritonitis, pulmonary tuberculosis, albuminuric hæmorrhagic cystitis, and she ultimately died of general dropsy.

Liebscher assures us that the clinical diagnoses were confirmed by post-mortem examination. The peculiar interest of the case lay in a punctiform deposit of calcareous matter throughout the body, which was easily demonstrated with the microscope. It was found in the intima of the arteries extending in many places to the deeper structures of the vessel. The calcification seems to have been at first located only in the fibrous tissues, and becoming retrogressive it was absorbed and redeposited in the internal organs, which gave a gritty feeling to the heart, spleen and liver at the post-mortem. This led to a closer examination of the tissues, particularly in all the serous and mucous coverings.

In regard to the ætiology, it is assumed that the kidneys became early affected, and chalk being locally deposited and then absorbed was locating in the blood at the time of the renal attack, being arrested and deposited in the mucous and serous membranes, as it was present in equal amount in the bronchi, alimentary canal and internal ducts, but *not in the veins*, as the presence of carbonic acid in the venous blood would prevent any deposit by holding the chalk in solution.

PERLSUCHT OR DIPHTHERIA?

Weleminsky showed a pleura and pericardium with "perle" nodules which he had taken from a cow, and which yielded typical tubercle bacilli as well as diphtheritic bacilli repeated in pure cultures. After different tests of colour and animal injections it was concluded that the bacillus was a degenerate form or pseudo-diphtheritic bacillus, as it had no virulence when injected into guinea-pigs, and did not react to Neisser's staining.

He also showed three preparations of actinomycosis of the lower jaw in cattle, from one of which he obtained a brick-red form, which seemed to be a degenerate variety.

TETANUS.

Zupnik related the history of a case of tetanus presenting many points of interest. The patient was a male, æt. 42, who, in consequence of a fall from a scaffold, sustained fracture of the sacral bones and extensive contusion, which caused paralysis of the lower part of the body, and subsequently acute purulent cystitis, associated with hæmorrhage. A 2½ per cent. solution of gelatine was injected to relieve the symptoms, but thirteen days later an unexpected attack of tetanus set in. Within twenty-four hours from the first appearance four full doses of Behring's antitoxin were injected, but in spite of every effort to relieve he died, after forty hours' suffering. The tetanus bacillus was found in the urine during life as well as on the surface of the mucous membrane after death. Its cultures were made and injected into animals with a positive result. The tissues in the neighbourhood of the wounds were examined with a negative result so far as the presence of the tetanic bacillus was concerned.

Zupnik concluded that only one hypothesis of the entrance of the toxin was admissible, viz., by the bladder from the gelatine, which he said would be the sixth recorded case from the same cause. He would therefore propose that henceforth all gelatine for medical use should be carefully sterilised before being employed.

He further added that the lower extremities, which had been four weeks paralysed by the accident, remained quite free from the muscular spasms, and this, he thought, confirmed the pathogenesis of the disease, as the paralysed muscles, being inactive and in a condition of degeneration, were virtually cut off from the body. Sero-therapy must be considered useless, he said, as the quantity required in animals varied with the sensitiveness of the animal; for example, an infected guinea-pig on the first symptoms had 250 A. E. injected, which is taken as the unit or standard, as to which man is calculated to be ten times more sensitive, an estimate which leaves the experiment somewhat indefinite. Repeated doses are worthless.

Another example actually under observation may be recorded where 1,000 A. E. was administered in puerperal tetanus without the slightest effect.

Chiari remarked that tetanus sometimes became epidemic, as it did recently in the Lying-in Hospital of Prague, thus proving the presence of the tetanus bacillus in the floor of all the wards. In this way instruments, if not carefully sterilised, might convey the germ.

Hering asked whether the gelatine injection used was examined for the tetanus bacillus, and whether any of it had been injected into animals. He expressed himself dissatisfied with the explanation of the cord lesions being attributed by Zupnik to degeneration of the muscles. If the contractions came from the cerebrum it is evident that they would not reach the legs, as the nervous connection was divided in the lumbar region, and all motor impulses cut off. It is generally understood that the brain is the principal habitat of the tetanus bacillus, which would not have involved the cord at death.

Bonn had no doubt about the presence of the tetanus bacillus on the ward floors, and thought not only gelatine should be sterilised, but also the linen, bandages, &c., which were just as dangerouss in wound and during parturition.

Weleminsky referred to the ubiquity of the germ, and to the occurrence of epidemics which he thought ran parallel with typhoid and scarlet fever, which led him to believe that sanitation had much to do with the occurrence of these fatal cases. Removal of sewage or anything that tended to lower the vitality was the best means of sterilising, while the best prophylactic was to immunise with tetanus serum, but it must be sterilised at the time and not kept in stock. Personally, he thought he had got as good results from the testicular juice of the horse.

Schwarz urged that nothing short of repeated boiling of the gelatine was effectual to obtain sterilisation. He had lost a patient recently owing, he believed, to the bacillus or ova not being quite destroyed before use. It was a severe case of melena neonatorum, gelatine was injected with the best result, but the germ lurking in the clot induced tetanus shortly afterwards with a fatal result.

The meeting finally agreed to Zupnik's proposition that pharmacists should keep nothing but perfectly sterilised gelatine for immediate use.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

Malignant Disease (Epithelioma) of Antrum.—Mr. Mayo Collier operated on a woman, æt. 63, the subject of a large malignant growth of the left upper jaw. This growth had apparently commenced in the antrum, and had extended downwards so as to involve most of the alveoli and adjacent portions of the bone. It extended from the left lateral incisor tooth to the last molar, and was invading the palate and outer aspect of the jaw. An examination of a small portion of the growth proved it to be of the epitheliomatous type of malignant disease. A pin having been previously passed under the facial artery, which was then compressed by a loop of silk, an incision was made in the middle line of the upper lip and carried round the alæ nasi to the margin of the orbit, and from thence outwards to the root of the zygoma. Mr. Collier rapidly removed the soft tissues from the upper jaw without encountering any troublesome bleeding. Care was taken not to open the nose cavity in removing the flap from the side of the alæ nasi. The central incisors having been removed, the saw was introduced into the nose, and the hard palate divided in the middle line. The malar bone was next sawn through, and the incision carried into the outer wall of the orbit with a pair of fine bone cutters. The nasal process of the superior maxillary bone was the last to be divided. The orbit with its contents was gently lifted up from the orbital plate of the superior maxillary bone, and the soft palate carefully separated from the hard palate with curved scissors. Up to this there was no trouble with the bleeding or difficulty with the anæsthetic during the operation, the patient, having been kept on her left side with the head slightly dependent. The whole upper jaw being now free, it was grasped and removed entire, without fracturing any of its surfaces. The soft parts were carefully adjusted, and the patient returned to bed with the face downwards, to facilitate drainage. Mr. Collier remarked that this was an unusual growth. It had evidently commenced in the antrum and after nearly filling the cavity had extended downwards so as to involve the avleoli and adjacent parts of the palate and jaw. Although serious difficulty with the bleeding and with the removal of the softened upper jaw was to have been anticipated, with a little care both these troubles had been avoided. He pointed out that the temporary occlusion of the facial artery was a great help, and the position of the patient facilitated the rapid performance of the operation without fear of suffocation from the entrance of blood into the respiratory tract.

Irish Medical Schools' and Graduates' Association.

The summer general meeting of the above association was held at Owens College, Manchester, on Wednesday, July 30th. In the absence of the President (Sir Philip Crampton Smyly), the chair was occupied by Dr. Richard Fegan (Blackheath). Among the other members present were Drs. P. S. Abraham, J. Chestnutt (Howden), W. Douglas, Stanley Gill (Formby), Sidney Gramshaw (Stillington), T. Adrian Greene (Ennis), J. Mills (Ballinasloe), A. Morton (Halifax), J. Goodwin Shea (Chesterfield), Oscar Wood (Cork), and the two honorary secretaries, Dr. J. Stewart (Clifton) and Dr. J. H. Swanton. The Council reported that Wednesday, November 26th, had been fixed for the banquet to be given to the Commander-in-Chief by the Association, at the Hotel Cecil, London, and that the Countess Roberts and their daughters had also accepted invitations to dine on that evening. The Council also reported that a considerable accession to their numbers had been made since the annual general meeting, and that there was a prospect of the total number of the roll reaching 1,000 members before the date of the banquet to Earl Roberts. A vote of thanks to the Council of the College for the use of the room terminated the proceedings.

Women Doctors in Germany.

During the years 1901 and 1902 only one lady took her degree as a doctor at the Berlin University, but altogether during last year no fewer than fourteen ladies have taken medical degrees at German universities. Of these lady students only six were Germans. Five passed at the Halle University, three at Heidelberg, two at Göttingen, one in Berlin, one in Breslau, one at Freiburg, and one at Munich.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 20, 1902.

THE VACCINATION MOVEMENT.

IT is really high time that the problem of ensuring universal and efficient vaccination should be removed from the sphere of politics and brought back to its proper domain—that of intelligent public opinion. Londoners have had a sharp lesson in the epidemic upon which the hatches are now well-nigh closed down. It will have taught them, and through them the world at large, with what readiness small-pox spreads among an imperfectly protected community, and with what difficulty its spread is checked, in spite of a system of notification, removal and isolation unsurpassed anywhere in the world. The cost of even this comparatively small epidemic—small, that is, compared with the number of inhabitants—has added half a million sterling to the burden of the ratepayer, who can derive little satisfaction from the reflection that he is paying the penalty of ignorance, indifference and neglect. Small as it has been, compared to what it might have been, this epidemic has cost 1,500 lives, besides endangering and probably embittering nearly 8,000 more. There is an universal consensus of opinion among those best qualified to judge as to the protective influence of vaccination, and every succeeding epidemic affords conclusive and irrefragable evidence of the immunity of the vaccinated; yet, in this country, owing to the exaggerated influence of a small but active minority, the enforcement of this invaluable safeguard is subordinated to purely political considerations. Under these circumstances, we are pleased to chronicle the formation of the Imperial Vaccination League, with the declared object of promoting the study of the laws regulating vaccination, in view of such improvements and modifications as may appear desirable. The Vaccination Act (1898) expires at the end of next year, so that fresh legislation of some kind will become necessary within the near future. The experience obtained in Germany, where vaccination and revaccination are rigidly enforced, affords ample justification for a determined effort to avert future epidemics of small-pox in this country. It is not proposed to go back on the exemptions at present accorded to "conscientious objectors," though no doubt steps will be taken to remove the irritating ambiguity of the present law in reference to this creature of prejudice. The number of children who have escaped vaccination since 1898 has considerably diminished under the new dispensation, although in three years (1898-1900) some 276,000 passed unhindered through the wide mesh of the law. It is generally recognised that something must be done to encourage, and, if possible, to enforce, revaccination, and this could be done by providing for the compulsory revaccination of school children at a specified age, a plan to which the freedom from small-pox in Germany is in large measure due. Then, too, the whole system of administration of the Vaccination Laws will have to be reconsidered. Public opinion, on the whole, seems to be favourable to the transference of authority from the guardians to the local sanitary authority. In this way the question of vaccination would be eliminated from the sphere of parochial politics, and the measure would be methodically enforced, just as with any other sanitary precaution. Then, too, it behoves the Government to make adequate provision for a supply of standard vaccine lymph. It is little short of scandalous that the medical profession should be left to the tender mercies of foreign institutions without any attempt to control the activity and the prophylactic efficacy of the products sold by them. Incidentally, no doubt, the desirability of perpetuating the office of public vaccinator under existing conditions may be called in question. The matter is one of national interest, and ought not to be left in any degree at the discretion of local authorities; indeed, the propriety of creating a special central department expressly to carry out the Vaccination Laws, is one of the questions to be considered by the League. One of the first duties of such a body would be to define "efficient vaccination," and to take steps to secure that standard of protection. The League will work in harmony with the Jenner Society, which has done so much good work since its foundation at the time of the Gloucester epidemic, and if it receive suitable financial support, much can be done in the direction of educating public opinion by the time the subject comes before Parliament. The influential list of signatories to the initial statement published by the League will command the respectful attention of all who are not blinded by unreasoning prejudice, and its propaganda will certainly receive the hearty and practically unanimous support of the medical profession. Let us then be up and doing!

TRADE UNIONISM AND THE MEDICAL PROFESSION.

THE attitude of journalists, as a class, can hardly be called sympathetic with regard to the medical profession. Otherwise we should not find them ready at every opportunity to hurl the taunt of trade unionism at the devoted heads of the "doctors," as the man in the street loves to call his learned medical advisers. In this way many of the points discussed at the recent meeting of the British Medical Association have drawn forth the familiar sneer in question from newspaper men on all sides. Thus a leading Liverpool journal says that the Association fulfils at least some of the functions of a trade union. Unfortunately, the accusation is not sustained by particulars, so that it is impossible to discuss the grounds on which it has been advanced. Clearly the imputation of a spirit of trade unionism is intended to convey more or less serious reproach, and it may be well therefore to consider calmly and reasonably what is the inwardness of this attitude on the part of a large section of the lay press. The definition of trade unionism is simple enough; it may be taken to mean the organisation of any given body of persons engaged in a particular pursuit, for the protection and furtherance of their peculiar common interests. In that sense trade unionism has been an enormously potent factor in the social life of the community. Although a weapon of modern introduction, at any rate as applied by the masses, it has played a most important part in the welfare of the industrial population of the United Kingdom. To take a particular instance, say, that of the colliers; by organisation they have secured for themselves reasonable hours of labour and a fair living wage. In the days before the principles of trade unionism had been grasped by the artisan his lot was for the most part deplorable. The results of trade unionism, then, have certainly sufficed to show that the movement is able in some instances to enforce what may be termed the natural rights of the workpeople engaged in various trades. So far, there would not appear to be anything heinous even if trade unionism were adopted forthwith by the medical profession, which has its interests to protect no less than other professions and pursuits. As a matter of fact, the lawyers have long established a trade union of the closest texture, with rules of the most stringent and detailed kind. In their case they have taken care to secure protection of their professional interests both by adequate legislation and by the machinery of what is probably the strongest trade protection society, if we may use that term, in the world, namely, the Incorporated Law Society. The result is that unqualified legal practice is practically non-existent in the United Kingdom. That is trade unionism with a set purpose and a definite outcome, yet we never hear the newspaper men inveighing against the lawyers and their trade unionism. What then, is the difference as regards the medical profession, which is protected with feeble laws and by an invertebrate and non-representative General Medical Council? The difference is that there is practically no protection of the interests of the medical profession. They are faced with wholesale competition from unqualified practitioners, and from the medical charities themselves, their fees are inadequate and often depressed to starvation pitch from sheer lack of common-sense organisation of the kind that has long ago been adopted by miners, and carpenters, and lawyers, and other sections of the community. If the evils springing from a lack of organisation are to be met with an application of the principles of trade unionism, then there is much to be said in favour of establishing medical unions of that nature forthwith. The fact of the matter appears to be that the public has got accustomed to the unbusinesslike muddle in which the medical profession keeps its domestic affairs. The journalists simply echo that sentiment when they sneer at any attempt on the part of medical men to remedy some of their manifold grievances. We should like to know how much benefit the journalists have derived from their own trade union? Apparently for some mysterious reason the medical profession alone is to be denied the right of organisation to protect its professional rights. The sooner medical men face the matter squarely and call a spade a spade the better for the dignity, the honour, and the social and material welfare of the profession as a whole. Let them have their Incorporated Medical Society on the model of that of their legal brethren.

PROGRESS IN RENAL DIAGNOSIS.

The endeavour to devise some trustworthy means and method of obtaining the urine of either kidney separately has for some years exercised the intellectual and mechanical skill of a good many surgeons. And very deservedly; for the object is one of the most important for obtaining a trustworthy diagnosis and prognosis in many obscure cases of renal trouble. The condition of "the other kidney," in many cases which suggest nephrectomy, cannot by any known means be even approximately guessed at without obtaining an unmixed specimen of the secretion of the latter. Simon, "the first surgeon to deliberately do the operation of nephrectomy," recognised the importance of obtaining the renal fluid from a single ureter, and for this purpose suggested compression of the other ureter against the brim of the pelvis—by the hand introduced into the rectum. Davy's lever was afterwards substituted for the hand. Next appeared Ebermann's forceps, which was made to compress the ureter between one blade in the bladder and the other in the rectum. Tuckmann's forceps was introduced into the bladder, and with it the vesical end of the ureter was seized and compressed. Then came Polk's S-shaped catheter, between which and a finger in the rectum the ureter was seized and occluded; next arrived, for female patients, Silbermann's vesical rubber bag, which was arranged on one side of the bladder and then filled with mercury for gravid pressure on the end of the ureter on that side. Fenwick's curved catheter with a lateral orifice was made to catch the urine as it escaped from the ureter. Neumann invented a double catheter, the canals of which were intended to draw off the urine, respectively, from two vesical pockets made by the forward pressure of a finger in the rectum. Hegar suggested cutting down upon the ureter in the anterior vaginal fornix, when it could be directly compressed. Ventral cœliotomy was advocated by some surgeons; Edebohes, so late as 1898, recommended exploration of the kidney through the loin, and Mr. Henry Morris, in his recent book, teaches us that it is more desirable to explore each kidney through the loin than to expose the ureter to infection by direct catheterisation. Simon devised a speculum which was introduced into the bladder, by means of which light was reflected and utilised in catheterisation of the ureters; and Howard Kelly introduced, and successfully practised, some improvements in his method. All these procedures, except that of Howard Kelly, have now been abandoned—and deservedly so. There is no doubt that the extreme difficulties and—very obvious—dangers which attend catheterisation of the ureter make it an unsatisfactory and undesirable procedure. The whole subject has been made the text of an important and well-thought-out communication to the *Australasian Medical Gazette* (May 20th, 1902) by Mr. H. L. Maitland. This writer judiciously indicates the difficulties and dangers of ureteral catheterisation, and recommends for the examination of the separated urine the recently devised "segregator" of Professor Malcolm Harris, of Chicago. This instrument consists of two metallic catheters enclosed in a sheath. When so introduced into the bladder, they are separately rotated till the respective ends dip into pouches formed on either side of a longitudinal projection produced by the pressure of a septum introduced into the rectum—in case of a female patient, into the vagina. The distal ends of the catheters have, each, a small bottle connected to it by tubing; from which the air is then abstracted by means of a bulb. There is, of course, some danger that the secretion so obtained on either side is not quite pure and unmixed; or the tricklings from the lining of the bladder cause some impurity—both from the previous contact of the mixed renal secretion, and from that of the vesical mucous membrane, if abnormal. But with repeated examination these objections can be pretty fully removed. Mr. Maitland is satisfied that the results are trustworthy—by demonstration: first, in the case of a patient with but one kidney, from whom the other had been removed; and, secondly, by the facts elicited in connection with subsequent operation. His conclusions, with which we entirely agree, are as follows:—"The segregator will aid in making a diagnosis in any of the following conditions:—First, in pyuria it will establish the source of pus. Secondly, if the pus be renal in origin, it will show us from which side it comes. Thirdly, in hæmaturia, if it be renal in origin, it will also tell us from which side it comes. Fourthly, it will aid in localising obstructions to the ureter, and determining whether such obstruction be permanent or intermittent. Fifthly, it also establishes the presence of both kidneys. Sixthly, it will aid us in a differential diagnosis of some abdominal tumours. Seventhly, it also enables us to find out the capacity for secretion of each kidney." In conclusion, we feel it our duty to express the opinion that Mr. Maitland's communication speaks highly for his own surgical enthusiasm and attainments, and for the progress of surgical knowledge in the far-off Australian Continent.

Notes on Current Topics.

Cancer in India.

The subject of the extent and prevalence of cancer in India, which has recently been receiving a good deal of attention, is dealt with in an interesting and instructive article by Captain W. I. Niblock, I.M.S., in the May number of the *Indian Medical Gazette*. The data are extensive, and consequently important and instructive. Captain Niblock has gone carefully through the registers of the Madras General Hospital, and "noted down all cases of carcinoma, sarcoma and rodent ulcer which have been admitted into the hospital during the past ten years. I have also made out a separate list of cases shown as suffering from 'malignant disease,' which term I take to be synonymous with 'cancer' in its broader sense." Among the very interesting results obtained by this investigation we find that "carcinoma of the cheek alone accounts for almost one-third, and carcinoma of the cheek, jaws, and tongue, taken together form more than one-half of the total admissions. The cheek is the part most commonly affected in Hindus and Mahommedans, males and females. The disease affects the buccal surface of the cheek, generally commencing opposite the teeth of the lower jaw and spreading with varying rapidity." Captain Niblock refers the frequency of cancer in this position to the national habit of chewing betel. This item of Oriental luxury is said to be made up of "(*a*) the *essential* constituents—viz., betel leaf, areca nut, and caustic lime (chunam); (*b*) *condiments*, such as cloves, nutmeg, cardamoms, cubebs, &c. Dry powdered cocoanut and oil are also sometimes added. The above components are mixed in varying proportions, rolled up in a betel leaf, and placed in the mouth. They are then chewed and rolled about by the tongue and cheek for a period varying from ten to thirty minutes, and then spat out." Cancer of the cheek is specially prevalent on the West Coast—particularly in Malabar. This great frequency is ascribed by the writer partly to the fact that the people of that part of the peninsula are in the habit of chewing betel which contains a large proportion of caustic lime. So that the chewing of betel in India corresponds to the smoking of the short black *dhudheen* in Ireland, as a cancer-generator. We must, however, also observe that Captain Niblock notes that "on the West Coast the chewing of tobacco is also very prevalent." Another fact offering an interesting contrast is that "*rodent ulcer*" is "extremely rare in the Madras Presidency." Yet another specially significant item of contrasted information is supplied by the fact that there were 201 admissions for cancer (epithelioma) of the penis, all of whom were Hindus—there was not one Mahommedan. The Hindus are not circumcised except in special instances, whereas all the followers of the Prophet are submitted to this operation at an early age. The value of the hygiene of circumcision, especially in the lower orders, may be said to be proved by this evidence alone.

The King's Visit to the College of Surgeons.

Last week his Majesty paid a visit to the museum of the Royal College of Surgeons of England, and although the visit was strictly private we are probably not committing any indiscretion in stating that its object was to enable his Majesty to understand more fully, from an examination of the numerous specimens of appendicular lesions contained in the museum, the nature of the affection which has cost him so much suffering and the nation so much anxiety. He was accompanied by Sir Frederick Treves, who no doubt explained the anatomical and pathological peculiarities of this disease, which, so far as as our knowledge of it goes, is distinctly of recent creation. This is probably the first occasion on record on which a member of the Royal Family has directed his attention to the, to the general public, gruesome collection which owes its inception to the enthusiasm of the great John Hunter, a collection which possesses associations other than genial for many practitioners who, at some period in the unforgotten past, have been subjected to the ordeal of naming possibly the very specimens which Sir Frederick Treves discoursed on to his Majesty, presumably in tones very different to those which he assumes when his audience is limited to a mere candidate for the diploma of membership.

Curious Censure of an Asylum Staff.

Broken ribs in asylum patients demand most careful investigation as to the way in which they have been caused, and the frequency of their occurrence in any given institution forms a serious indictment of its methods. At the same time it is absolutely impossible to prevent the occasional fracture of ribs in violent maniacs. So far as can be judged from a perusal of the account of an inquest reported in another part of the present issue the five broken ribs found post-mortem in deceased belonged to the unpreventible margin. The patient appears to have been in such a condition that he fought everyone he came near, including the police who brought him to the asylum. He was there placed in a refractory ward, where he at once knocked down an attendant and engaged in a desperate fight with another patient, by whom he was seriously knocked about. It was only after these exhibitions of violence that he was placed in a padded room. The jury probably were influenced in their verdict by the fact that so dangerous a patient was turned loose into a ward with other inmates. At any rate, they censured the officials, and explained that they meant to include both medical staff and attendants in their censure. The verdict would hardly be sustained by a Court of Appeal.

The King's Sanatorium.

The fact that 180 schemes for the King's Sanatorium were submitted for competition is abundant proof of the widespread practical interest which is now being taken in the rational treatment of the consumptive. It is satisfactory to find that the fortunate physician who has gained the first place in the international competition is an Englishman, and although perhaps slow to initiate new movements as a people, when thoroughly moved we certainly "take a deal" to stop us. We suppose the prize schemes will be duly published, but we venture to suggest that much benefit would accrue from the publication of all the schemes submitted, or at all events all except those that are manifestly worthless. The minds of physicians and architects are being turned to the matter in all parts of the world, and suggestions and material for criticism of all kinds are to be welcomed. We trust that means may be found for the publication of all the schemes worthy of consideration, without delay.

Mortality Returns of Animals.

Man spends much of his life in close association with domestic animals. It is only of recent years that we have begun to realise the importance of the spread of disease from animals to man, and at present we know but little regarding the converse. Comparative pathology as a serious study is but of yesterday. Our knowledge of human ailments is still very limited. The mortality returns as regards man are ludicrously imperfect. But the time will doubtless come when haphazard procedure will give place to methods directed with scientific precision. And meanwhile it may be well for us to remember that it will be necessary to secure sooner or later adequate returns as to the diseases of animals, and at least approximate statistics as to the mortality among domestic animals. Is it not possible for some enthusiast to attempt some such unauthorised return in a village or sequestered hamlet where every dog and horse is as well-known as the few inhabitants?

The Coronation Gift.

The Coronation Gift, amounting to £115,000, has been presented to his Majesty by the Lord Mayor of London, who expressed the pleasure he felt at the fact that the tribute embraced the offerings of the poorer classes of his subjects equally with those of the rich. His Majesty added that his object was to free the hospitals from debt, a purpose which, until it was accomplished, he should not cease to strive after.

De-nicotined Tobacco.

WE learn from a contemporary that a German chemist, Herr Gerold, has discovered a means of preventing the ill-effects which sometimes arise from the excessive use of tobacco, which is liable to produce attacks of vertigo, a particular form of dyspepsia, palpitation, and diseases of the chest. His procedure consists in steeping the leaves of tobacco, before being made up, in a solution of tannic acid, which combines with the nicotine and forms a substance quite inactive and harmless. In order to increase the flavour of the tobacco, it is then treated with a decoction of marjoram. The flavour of the tobacco prepared as above described differs in no way from that of ordinary tobacco; and experiments made with it on weasels, frogs, and even human beings, have demonstrated that its use produces no toxic effects on the organism. The pressure of the blood remains normal, the heart beats regularly, and the paralysis which overtakes animals who have been poisoned with nicotine is entirely obviated. Our contemporary adds that all smokers will hail with satisfaction the discovery of Herr Gerold. We fear that, as a smoker, we can scarcely agree with this optimistic statement. Supposing that Herr Gerold succeeds in removing all the nicotine, what is left? We doubt that the vast proportion of tobacco smokers suffer from consequent dyspepsia, palpitation, and diseases of the chest, and believe that they will prefer to continue the use of tobacco than to adopt Herr Gerold's substitute. If, on the other hand, a smoker does suffer as our contemporary suggests, he had better refrain from the "noxious weed" altogether.

The Educational Number of "The Medical Press and Circular."

THE Educational Number of THE MEDICAL PRESS AND CIRCULAR will appear in the second week of September, a fact to which we beg to draw the attention of Hospital Registrars and Secretaries of Medical Boards. This number will, as usual, contain all necessary particulars and information regarding the medical curriculum which may be of use to intending medical students, and will devote special space to notices of the different hospitals and medical schools. In order that we might be able to lay the latest information regarding these various schools and hospitals before our readers, we some time ago sent to the secretary of each of them a copy of the paragraph dealing with their school or hospital which appeared in our last Educational Number, with the request that all needed alterations should be made, and the slip returned to us. Some of these slips have been returned, but up to the present others have not been returned. We would point out to the secretaries of those hospitals from which returns have not been received that it is to their own interest that all information regarding their hospitals should be as accurate as possible and that we cannot be responsible for errors if no return is sent to us. Following the example of other journals, we shall in each case mark with an asterisk the names of hospitals from which returns have not been received. All such returns must reach the office of the Journal before September 1st, otherwise they will be too late for use.

Municipal Humanised Milk Depots.

ON many occasions we have advocated in this journal the importance of establishing depôts for the sale of sterilised humanised milk to the poor. The number of infants who die from diarrhœal diseases of a removable origin in our large cities is appalling, and has so far been unaffected by the best wishes of humanitarians. The futility of lessening this mortality by such well-meaning efforts as the instruction of the mothers as to the necessity for suitable infant food, without at the same time providing them with such food, is recognised by most people, but so far, with one exception, few attempts have been made to remove this stumbling block. The Borough Council of Battersea have established municipal depôts for the sale of sterilised "humanised milk" exactly on the lines which we have advocated, following the example of Manchester. The milk is supplied in stoppered bottles, each of which contains sufficient for one meal, and from six to nine of these are fitted into a small wire basket. The cost of a week's supply is one shilling and sixpence, or about twopence-halfpenny per diem. The Battersea Borough Council are certainly to be congratulated on having adopted the only practical means of diminishing infant mortality in their district. Is it too much to hope that the Municipal Councils of some of our Irish cities will spare sufficient time from political matters to enable them to look after the well-being of the youthful population in their charge?

Testicular Cyst containing Acari.

To the many dangers which attend the passage of an imperfectly asepticised catheter must be added a new one, the possibility of carrying living acari into the urethra. Mr. R. J. Pye-Smith, F.R.C.S., in the current issue of the *Quarterly Medical Journal*, records a unique case in which a colony of acari of a hitherto undescribed species was found in the contents of a testicular cyst in the neighbourhood of the epididymis. The patient, a medical man, had spent a short time in India, whilst there he had been catheterised for retention of urine, and not long after that the cyst appeared. Mr. Pye-Smith tapped the latter and drew off two and a half ounces of a watery fluid, part of which he sent to Dr. Hector, University College, Sheffield, for examination. On microscopical examination a single drop of the fluid spread on a slide showed on an average ten acari in each field, and also rounded bodies which were probably ova. Recognising that the acari were specimens of the itch mite, and being unable to identify them, Dr. Hector sent them to Dr. E. Trouessart, of Paris, who has made a study of this special field of biology. In the course of a long report Dr. Trouessart says that he was convinced that the acarus was a sarcoptide, of the sub-family Tyronliphinæ (Sarcoptides detriticoles), nearly related to Histiogaster carpio, Kramer, but a new variety, which he proposes to call Histiogaster spermaticus. The acarus had probably been introduced along the catheter, and passed thence on to the urethral mucous membrane, from which it had journeyed along the ejaculatory ducts and vas deferens to the epididymis.

Carcinoma a Cause of Appendicitis.

Among the etiologically distinct diseases grouped under the term appendicitis, primary carcinoma of the appendix is one which has of late attracted some attention. The existence of a primary malignant condition of the mucous membrane and its extension to the other structures of the appendix has been established in about thirty cases, but in only ten or eleven was the disease obviously limited to that organ. It is impossible to decide the exact relationship of the carcinoma to the appendicitis, and we are fain to fall back upon the generally received view that chronic irritation favours malignant degeneration. The fact that in a large proportion of the cases surgical intervention, with ablution of the diseased appendix, afforded permanent relief, suggests a doubt as to the trustworthiness of the diagnosis based, as it is, purely upon microscopical examination of the tissues. Useful as are the data afforded by the microscope it is a matter of common knowledge that such evidence falls short of absolute certainty, and clinical observation not unfrequently belies the prognosis based on microscopical examination.

Grape Juice.

The unfermented juice of the grape, taken in large quantities, produces very marked physiological effects, advantage of which has been taken in the treatment of various diseases. Experimental investigation shows that its administration is followed by a marked increase in the secretion of urine, the acidity of the urine being reduced not only qualitatively but absolutely, the proportion of uric acid undergoing considerable diminution. On the intestinal tract it acts as a laxative, and it is also stated to restrain intestinal fermentation, this no doubt being a collateral result of its evacuant properties, and not directly due to any antiseptic action of its own. In virtue of the large proportion of glucose which the juice contains in solution, it economises the metabolism of the nitrogenous elements of the tissues and thus favours the deposition of fat, a fact worth bearing in mind in the treatment of diseases accompanied by rapid wasting, such as tuberculosis. Incidentally it stimulates the hepatic functions and promotes the secretion of bile. The "grape cure" is very beneficial in various types of dyspepsia, especially those associated with constipation Although best carried out in countries where the vine is a staple article of cultivation, the treatment, in a modified form, is available anywhere.

"Pneumonia Blouses."

Nothing is more difficult to ascertain aright than the effect of dress on the health of women. If pride is never hurt, then surely fashion never fatigues and dress is faultless of disease. But at the dictates of fashion an important experiment has been conducted on a large scale this summer. For many generations the demands of evening dress have necessitated free exposure of the feminine thorax, but during recent months adequate covering of the chest of most women has been conspicuous by its absence even during morning shopping and at afternoon garden parties. And this custom has prevailed when the manly bosom has sought protection in wraps and overcoats. "Open-air" treatment, it would appear, is to have a wider significance than we have hitherto thought. We are quickly learning to shake ourselves free from ancient medical prejudices and to discard old-time hygienic considerations. Contempt for much of the so-called sanitary counsels of the past has given rise to unwarranted and reckless indulgence in "natural" methods and "savage" customs. The question now awaiting answer is how far such "exposure" procedures are to be considered detrimental to health. In short, do "pneumonia blouses" merit their name? Experiments have shown that the direct action of cold upon the skin is capable of producing extensive irritative changes. Ice applied to the thorax or abdomen will produce marked congestion of the bronchial mucous membrane. Exposure to cold and draughts after violent exercise or when the skin is acting freely is said to be a fruitful cause of bronchitis and lung trouble. But can such evils occur to a woman arrayed in a dainty, low-cut, fashionable blouse? We trust some of our readers may be able to throw light on this interesting pathological problem.

Objectionable Advertisements in Religious Publications.

It is, unfortunately, only too true that parsons and retired military men often prove the warmest supporters of "quackery." Doubtless more or less adequate explanation of the fact might be presented, but to afford such is not at present our purpose. We wish merely to direct attention to the widespread prevalence of objectionable advertisements in so-called religious publications. Papers which should have been guided by the highest ethical considerations have permitted their advertising columns to become the means for unscrupulous persons to practise the most cruel frauds upon the poor and ignorant, many of whom innocently imagine that whatever appears in a religious paper must be honest and altogether trustworthy. The editors of many of these "religious" journals cannot claim release of responsibility on the grounds of ignorance. We know that in several instances some of the most honoured members of our profession have seriously sought to abate this scandal, but hitherto, we fear, with but little success. It seems incomprehensible that "religious" papers should for the sake of financial gain stoop to accept such advertisements as a high-class "lay" newspaper would rigorously exclude. Unless those responsible for the conduct of these "religious" papers can speedily make up their minds to clear their columns of such filthy and dishonourable advertisements as now find place in them we venture to think it will become a public duty to expose them to "the wicked world" as well as to "the religious public."

Alpine Accidents.

Switzerland has been well-termed the playground of Europe, but unfortunately it still proves to many a burial-ground. And much of the loss of life occurring on the mountains or glaciers is directly the outcome of ignorance or folly, the neglect of ordinary hygienic precautions, or the voluntary acceptance of unwarranted risks. Swiss guides are rightly praised for their prudence and endurance. In some districts they receive a certain amount of instruction in the principles of first aid, but generally speaking they are guides by "rule of thumb," or should we say "rule of foot"—at all events they frequently lack a knowledge of hygienic principles, and hence when calamity overtakes them the limits of their helpfulness are soon reached. The recent calamity on Mont Blanc is clear evidence of this. If the published accounts are to be taken as correct, the two young mountaineers who lost their lives, and the guide and porter who rushed headlong into disaster, had seriously lowered their powers of resistance to the low temperature to which they were exposed during the snowstorm by indulgence in alcohol. The experience of the best climbers, and the testimony of such Arctic travellers as Nansen, have clearly demonstrated the prejudicial action of alcohol when physical exertion has to be borne at low temperatures, and yet the findings of experiment and experience are constantly set aside, and only too often with disastrous results.

Ocular Fatigue and Winking.

It is generally admitted that the incandescent electric lamp affords the light least fatiguing to the eyes by reason of its constancy and mellowness, but this can only hold good in respect of quality, since the quantity of light best adapted to secure comfort varies according to the refraction of the individual as well as his sensitiveness to luminous rays. A Russian physician points out a simple method of estimating the degree of fatigue caused by particular methods of illumination, based upon a series of experiments under varying conditions. He found that a person working by candle light winked, on an average, six times a minute, while with gas light the average of winks was reduced to less than three per minute. In sunlight, presumably diffuse, the subject winked rather more than twice a minute, and with the electric light less than twice a minute. Of course, winking is only the indication and not the cause of the ocular fatigue, and it follows that winking deliberately indulged in for purposes foreign to the useful employment of the organs of vision may be indulged in with impunity, and afford no data from which physiological deductions can be drawn.

The Tuberculosis Question and Dr. Garnault.

The reception which Dr. Garnault's attempts at self-immolation on the altar of science has met with in the press of all countries is calculated to discourage others from following his example. It is perhaps as well that this should be so, especially as the problem which it is his object to decide cannot be solved by experiments conducted on the lines which he has so painfully laid down. Dr. Garnault appears to have omitted the indispensable preliminary step of proving that he was not already the victim of tuberculosis. This alone would vitiate any conclusions to be drawn from his inoculations. Then, too, the question is not so much whether it be possible by violent and altogether artificial means to transmit bovine tuberculosis to human beings as whether such transmission can take place from the ingestion or inhalation of infected material. Professor Koch treats the experiment with a scathing sarcasm which has excited the ire of the French press in general. These, however, are conditions unfavourable to dispassionate scientific research, and if the professor's postulate is to be disproved it will certainly not be by experiments carried out in such a heated atmosphere.

Adiposis Dolorosa.

An interesting case of *adiposis dolorosa*, or *Dercum's disease*, has been placed on record by Dr. E. Angus Johnson. The subject was a female, æt. 32, married thirteen years, but still a nullipara. At the time of her marriage she weighed 7st. 9lbs. "Eight years ago she noticed that her stomach was getting larger, and very tender on pressure (the pain being compared to that of a bruise). Then the hips, chest, arms, and legs got bigger. Pains of a neuralgic nature under the left shoulder, which have been worse since the influenza; also neuralgic pains on crown of head, across the forehead, and particularly over the left temporal region. There are frequent hot flushes of the face, followed by cold, clammy sensations; also giddy sensations, with a feeling as if she is going to fall backwards. Locomotion is difficult, and a very short walk is followed by great breathlessness and palpitation, her nervous equilibrium being upset over most trivial matters. When she 'catches a cold,' the pain in the chest is so severe that she cannot sleep on its account. Standing for any length of time causes severe pain in the ankles and knees (which do not swell); this also prevents sleep." The face is not affected, and on that account has the curious aspect of looking too small. The thyroid gland, so far as its outlines can be made out, appears to be unaffected. The thoracic and abdominal walls present great deposit of adipose tissue; on the latter "whilst in the recumbent position big folds of fat are produced. This is tender on manipulation or slight squeezing, the pain, as already noted, is likened to that which follows a bruise, the skin bruising on very slightly squeezing it." The temperature and heart's action appear to be normal: pulse 96. The hands and feet appear normal except for a slight fulness of the thenar, hypothenar, and plantar eminences. No muscular wasting can be detected. The headache, vertigo, palpitation, and sleeplessness are intensified at menstruation. The *tout ensemble* suggested to Professor Watson, who saw the case in consultation, the happily descriptive epithet of ambulatory lipoma.

Kahler's Disease.

IN a recent number of the *Rivista Critica di Clinica Medica* Dr. E. Donetti reports a case of "Kahler's disease," a pathological condition so rare that only sixteen cases have been reported up to the present. The characteristic symptoms of the affection are emaciation, weakness, marked anæmia, pains in the bones, with softening and fractures, and various deformities. Heteroalbumose is found in the urine in an earlier or later stage. Post-mortem examination displays the presence of sarcoma-like growths in the ribs, sternum, and bodies of the vertebræ. This first invades the marrow, and afterwards destroys the osseous tissue. Lesions of the solid viscera—kidney, liver and spleen—have also been found. It would appear that when the bone marrow is rendered unable to perform its normal physiological functions the new substance—albumose—is formed by the established pathological conditions. This causes a true intoxication, which is the immediate cause of the fatal result.

A New Surgical Departure in Neuritis.

DRS. CHIPAULT and Le Für have recently inaugurated a new advance in the treatment of a special form of intercostal neuralgia. A man, æt. 48, had for a period of four years suffered excruciating neuralgic pains in the course of the eighth, ninth, and tenth intercostal nerves of the right side and around the umbilicus. There were violent crises, which had been proving worse as the case grew older. He had been treated at various hospitals, and heavily dosed with the usual anodynes—even up to eighty centigrams of morphia *per diem*—without any permanent improvement. He had, in consequence, lapsed into a deplorable state of general health, and had frequently contemplated suicide. The crises occurred at intervals varying from a few minutes to several hours. There was also a zone of hyperalgesia corresponding to the distribution of the nerves mentioned. There was no evidence of tabes: the reflexes were rather exaggerated, and there were none of the usual vesical or rectal complication of tabes. The diagnosis arrived at was a "névrite radiculaire"—a neuritis of the roots of the nerves in question, at their origin from the spinal medulla. Accordingly, an incision was made vertically over the sixth and seventh dorsal spinous processes, which had been found by previous experiments on the cadaver to correspond to the level of the origin of the roots of the nerves in question. This was prolonged till room was made for the removal of three of the posterior vertebral arches. The dura mater was then incised; the three nerve roots sought for were fully exposed, and found to emerge from a well-defined and sharply localised area of cicatricial arachnitis. The affected arachnoid was removed, the diseased nerve-roots excised, the dura mater sutured, and the wounded soft parts brought together *secundum artem*. The patient left the hospital thirty-five days after the operation, free from pain. There have been some recurrences of the neuralgic crises since, but not nearly so frequent or so intense as before the operation. The success, although not perfect, has certainly been a very remarkable one; and Drs. Chipault and Le Für may well be congratulated on having inaugurated a new and brilliant departure in the domain of surgery.

Intestinal Occlusion.

AT a recent meeting of the Surgical Society of Paris M. Rochaud reported two cases of intestinal occlusion due to biliary calculi. The first case was that of a woman seventy-nine years old, who was admitted on the seventh day of her illness. The case was considered to be a neoplasm, and a laparotomy performed, when a large calculus was found in one of the loops of the small intestine. A simple incision liberated the calculus and the patient made a quick recovery. The second was analogous to the former. An aged woman was admitted to hospital three days after her sickness began. A laparotomy was performed, and a large calculus was removed from a loop of the small intestine, which, however, had become adherent to the brim of the pelvis. Thirty-six hours after the operation the patient died of general peritonitis. Such cases are very obscure, and the diagnosis can seldom be made until a laparotomy allows of the sense of sight as well as touch. The result as a rule, depends on the condition of the peritoneum at the time of operation.

Pneumonia in Children.

ONE of the many difficulties that beset the young medical practitioner in the beginning of his career is the diagnosis of the diseases of children. He has commenced with a clear perception of the physical signs of pneumonia in the adult and too often he has not had the opportunity of studying this common disease in the child. Besides the patience with which an hospital patient submits to examination is not to be found or expected in a child. Without frightening or disturbing the little patient the lack of expansion of the subclavicular region of the side affected is easily recognised by placing the finger-tips of each hand on the infra-clavicular region. The sign is a valuable one, and easy of recognition.

THE International Congress on the Care of the Insane will take place at Antwerp on September 1st.

THE Congress of German Scientists and Physicians meets at Carlsbad on September 21st.

Nurse Beattie Again.

Nurse Beattie, she who attained a measure of notoriety in consequence of her persistent attacks on Dr. Cullingworth for having, as she alleged, operated not wisely but too well, has made another appearance as plaintiff, this time at the West London Police Court. She poured into the magistrate's sympathetic ear a tale of woe, alleging that she had been boycotted at all the London hospitals in that, although an operation had been declared to be necessary, she could nowhere find admission with that object in view. Really Nurse Beattie is unreasonable! Can she humanly expect any surgeon who values his peace of mind to incur the risk of the worry and expense to which she deliberately subjected the philanthropic surgeon who gratuitously placed his skill at her disposal on a previous occasion? One surgeon in her opinion operated too much, and the others not enough. The magistrate opined that if proper representations were made means would be found to secure her admission, but he overlooked the fact that though one man can lead a horse to the water twenty cannot make him drink. In deciding on an operation all the circumstances of a case must be taken into consideration, and there is one circumstance in this case which would indispose any prudent surgeon to assume the responsibility of undertaking it.

The seventy-fourth annual meeting of the Congress of German Scientists and Physicians will be held at Carlsbad from September 21st to 27th.

The annual meeting of the British Association will take place this autumn at Belfast.

PERSONAL.

Dr. Harrison, of Keynsham, sustained a compound fracture of the left arm a few days since while playing in a cricket match at Kingswood.

Surgeon General J. A. Clery, C.B., Army Medical Staff, just promoted to that rank, has been appointed Principal Medical Officer of the Transvaal and Orange River Colony.

Mr. E. Hurry Fenwick will preside at the annual dinner of the London Hospital Medical College, which will be held in the College Library on Wednesday, October 1st.

Dr. Rina Mastio has been appointed Professor of Anatomy at the University of Milan, the first occasion on which a woman has been nominated to a chair at an Italian university.

Colonel R. M. O'Reilly has been nominated to succeed to the post of Surgeon-General of the United States Army, which becomes vacant in September next by the resignation of General Forwood.

Mr. F. H. May has been appointed rector of the Hong Kong College of Medicine for Chinese, in succession to the Hon. J. H. Stewart Lockhart, C.M.G., who was recently appointed High Commissioner of Wei-hai-Wei.

Dr. Benjamin Moore, Lecturer on Physiology in the Charing Cross Hospital Medical School, has been elected by the Council of University College, Liverpool, to the Chair of Bio-Chemistry, recently founded by Mr. William Johnston.

Sir Frederick Treves has accepted the invitation of the Liverpool Royal Infirmary to open two new operating theatres at that institution. His visit was fixed for October 11th, but as that is the date for presenting the freedom of the city to Earl Roberts and Viscount Kitchener he will probably pay the visit on Friday, October 10th, or Monday, October 13th.

As the result of an international competition arranged by the *Journal of Tropical Medicine*, Dr. Attilio Caccini, of Rome, has been awarded the Sivewright prize of £10, and Dr. Bruno Galli-Valerio, University of Lausanne, Switzerland, the Belilios prize of a similar sum, for essays on subjects connected with tropical diseases. The Lady Macgregor prize was not awarded.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

Carnegie Trust and the Scotch Universities.

From time to time notice has been taken in this column of the appeals made by the four Universities to the Carnegie trustees for grants in aid of their more pressing needs. The trustees have now considered these statements, and have drawn up a scheme for the distribution over five years of £200,000 among the four Universities. The annual income at their disposal for purposes of endowment (as opposed to the Fee fund) is probably not less than £50,000, so that meanwhile the trustees do not propose to ear-mark the whole of their resources. In his report to the Committee of the Trust of his visit to the Universities, Lord Elgin (the Chairman) states that he had thought it right to draw the attention of the respective Courts to two points. The first of these was the retention in the hands of the Executive Committee of the administration of any funds for the encouragement of post-graduate research. The second was the difficulty which would attend any extensive permanent devolution of the income of the Trust. He regards it as perfectly natural that there should be an anxiety to relieve the respective University funds, especially where, as in Aberdeen, that fund is weak, from the pressure of charges, notably those to lecturers and assistants, and to make some addition to quite inadequate salaries, and he admitted that immediate relief could not be obtained if the grants must all be used as grants towards capital funds or endowments. But he holds it essential to maintain this general principle, though limited sums may be voted in relief of deficiencies of income. Lord Elgin's conclusions on these two points were approved by the Committee, and the grants now announced follow on them. In connection with the second point, what is desired by the Trustees may be illustrated by the proposal for the better teaching of modern languages at Aberdeen. An annual sum of £2,500 is set aside, which is divided into two portions, the larger one (£2,000) being allowed to accumulate for five years for the purposes of endowment, the smaller one (£500) being placed provisionally at the disposal of the University Court to meet current expenses. If this scheme is adopted, the result will be to relieve the University Fund of the whole or nearly the whole of the charges presently thrown upon it (for this particular object), and at the end of five years to place it in possession of an endowment yielding £300 a year. The system is an attempt to combine the relief of present necessities with the provision of secured and permanent endowments. The trustees hope that the latter part of the scheme, which contributes to University endowment, may tend to accelerate its own progress. There are persons willing to assist in the earlier realisation of an object if a clear and strong lead is given. It is by no means necessary that the endowment funds so created should be used for the institution of new professorships or lectureships, but existing lectureships may instead be placed on a permanent footing, or raised to the position of professorships. Schemes for the proper endowment of assistantships may also be considered, for undoubtedly there is much to be said for making the departments already existing in the Universities thoroughly efficient before proceeding to endow new ones. At present the trustees have made no statement as to how they propose to endow research, beyond the fact that they propose to retain the administration of any funds for that object in their own hands. They have not thought it expedient to go beyond the questions raised by the statements of the University Courts, which have been specially remitted to them. But they cannot shut their eyes to the fact that the operations of the Committee may more or less seriously affect the interests of some of the extra-mural Colleges and institutions which have also claims under the trust deed. It is enough to say at present that these cannot be wholly ignored, and that therefore funds must be kept in hand to meet possible expenditure during the period of the grants now proposed. The present report, therefore, deals solely with the disposal of about four-fifths of the income in the hands of the trustees for a period of five years for the better equipment of the Universities, and leaves over meantime the question of original research and the treatment of educational bodies other than the Universities. Of the money now allocated Glasgow gets £11,000 annually, Aberdeen £9,000, St. Andrews £8,500, and Edinburgh £11,500. In each case the sum allotted is to be devoted to (1) buildings and permanent equipment, (2) teaching, and (3) library. For the last-named object all the Universities are treated alike, receiving £1,000 per annum, or £5,000 in all. Glasgow gets £40,000 for providing accommodation for physics, physiology, materia medica, and forensic medicine, and the equipment of the chairs of chemistry and geology if there is any remainder. £10,000 is set apart for the endowment of teaching, of which £7,500 is to go to the chair of geology. In Aberdeen the bulk of the grant is devoted to teaching, a sum of £5,000 being set aside for buildings, and £35,000 for the former object. The greater part of this grant is to be devoted to the endowment of a chair of history, and the remainder to modern languages. In each instance £500 a year is to be used as provisional assistance for income of the chairs, the remainder to be allowed to accumulate. St. Andrews gets £15,000 towards building, disposed of as follows:—Chemistry £5,000, including endowment for upkeep: physics £2,000; extensions in Dundee £8,000. It also gets £22,500 for teaching, £10,000 for general purposes and £12,500 for modern languages. Here again a part of the grant is to be applied to income, and the bulk allowed to accumulate for five years. Edinburgh University has £40,000 allotted to it for buildings and permanent equipment in natural philosophy and engineering, alterations in library, apparatus, pathological bacteriology, and catalogue of anatomical museum. £12,500 is to be devoted to teaching—for endowment of modern languages or some other approved purpose. One cannot but feel that the Committee of the Trust have dealt with their responsible task in a wise and statesmanlike fashion, and if their dealings with the extra mural schools and colleges, and their treatment of the question of aid to original research are characterised (as there is no doubt they will be) by the same spirit of justice and farsightedness, they, no less than Mr. Carnegie, will deserve the thanks of all who are interested in higher and technical education in Scotland.

A widespread epidemic of cholera is raging in the north of China.

BELFAST.

[From our own Correspondent.]

I have alluded in this column on former occasions to the inquiry held by the Irish Local Government Board in reference to the alleged excessive expenditure on medicines and appliances at the Belfast Union Workhouse.

At a recent meeting of the board of guardians a letter was read from the Local Government Board directing the guardians to convene a meeting with a view to determine whether the medicine contractors should any longer be entrusted with the contract for supplying medicines to the workhouse. The letter also advises the guardians to impress upon their medical officers that the proper discharge of their duties involves not only skilful treatment of the sick under their charge, but also the due exercise of economy in requisitioning the articles required for their patients. In addition, it is to be expected that medical officers shall possess ordinary administrative capacity and a sense of responsibility in seeing that articles obtained under their signature are really necessary and are applied to the purposes for which they are ordered. The want of control over the nurses and their wasteful extravagance point, it is further stated, to lax discipline in the nursing staff which, having regard to the fact that the Belfast Workhouse Infirmary has become a large and important school for training, may, if not checked, have far-reaching evil effects. The Local Government Board requests the guardians to endeavour to provide for the proper supervision, education, and control of the nurses. As a result of the inquiry the Local Government Board concurs with the view of its inspector, Dr. Smyth, that the sum of £427 11s. was excessive, and it has accordingly disallowed recoupment from the Local Taxation (Ireland) account upon this sum. The reports of the medical inspector are to be carefully considered at a special meeting of the guardians.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE NOMENCLATURE OF SURGICAL OPERATIONS FOR UTERINE TUMOURS.

To the Editor of The Medical Press and Circular.

Sir,—I would like to take advantage of the reports of Dr. Giles' two cases in The Medical Press and Circular of July 16th and 23rd of tumour of the uterus, and refer once more to the nomenclature of the subject.

I am sure, on further consideration, Dr. Giles will agree with me that the names he proposes are far from being the best that could be used. He proposes three terms:—

1. Abdominal myomectomy is reserved for cases in which a subperitoneal pedunculated myoma is removed from the uterus.

2. Abdominal enucleation for cases in which a myoma is shelled out of the substance of the uterine walls.

3. Abdominal hysterectomy for cases in which the uterine cavity is opened and a tumour removed from its interior; these are all to be considered consecutive operations.

Now, may I venture to say that he would be a very indiscreet man, to say nothing more, who could even consider, in No. 1, where the tumour is entirely subperitoneal and pedunculated, anything else than merely removal of the tumour alone. There is no occasion for considering the uterus any more than any other internal organ. All sorts of tumours appear intra-abdominally, and the term, therefore, of myomectomy, as applied to uterine tumours is not only not sufficient, but misleading. The ordinary terms of general surgery should be used here, such as excision of so and so.

2. Abdominal enucleation is a still more unsuitable phrase. If it means anything it means enucleation of the abdomen—and that would never do.

3. Abdominal hysterotomy is, if possible, still worse. Taken at its best, it may be understood to mean cutting into the uterus, only this and nothing more.

If Dr. Giles would kindly refer to the very inefficient report given in the *British Medical Journal* of the paper I read at the Association meeting in 1894, he would there see that all that he refers to has been put down fairly and clearly by me, going perhaps even a little further than he may have gone yet, since I record several illustrative cases, and among them one where even with the fragments of a uterus after resection subsequent successful pregnancy and delivery occurred.

In this paper I suggested the use of a plain ordinary word, which by long use has come to be perfectly understood in general surgery, and I have no doubt its adoption into gynæcological practice would help to remove one of the barbarous innovations of special names in this branch as if it were not truly a branch of general surgery.

The word is "resection." It requires no explanation. Everybody understands resection—of bones, joints, muscles, nerves—in general surgery; a cutting or separating for the purpose of removing some diseased part, and then putting the separated parts together again, a truly conservative operation by name even. The word is simple, accurate and fits all kinds of cutting into the uterus for the removal of anything. It does not restrict one to a fibroma, a myoma, papilloma, or anything. It merely describes the operation and that is all that is wanted. The thing removed requires a separate description. If only Dr. Giles would lend his valuable aid with others like him in important public positions to adopt the simplest surgical names gynæcology would soon cease to stand by its nomenclature as something in its surgical aspect different from all other surgery.

I am, Sir, yours truly,
J. Stuart Nairne, F.R.C.S.
Glasgow, August, 1902.

GARLIC OIL AND PHTHISIS.

To the Editor of The Medical Press and Circular.

Sir,—It is doubtless to the sulphur, as sulphide of allyl contained in the essential oil of garlic, that the therapeutic effects of this oil are due. Your correspondent, Dr. Vivian Poore, in his work, page 278 (*a*), reminds his readers that many sulphides have been found of service in tuberculous diseases.

The sulphide that I have myself found of service, among others, has been the bisulphide of carbon of the British Pharmacopœia. Two drachms of the pure bisulphide may be dissolved in six drachms of rectified spirit, and four or five drops given in milk or in emulsion three times daily.

In chronic phthisis of cold and strumous temperaments I have found it useful; also in asthma and chronic bronchitis. That the sulphide is eliminated by the respiration is evident from the abominable odour it gives to the breath, and this is the great objection patients make to its use.

Externally, I have used the bisulphide in the proportion of one part to three of almond oil, and am able to speak well of it as a very useful application over any part of the chest where we suspect a deposit or thickening to exist.

One of the ward sisters in Victoria Park Chest Hospital gave the liniment the appropriate name of "onion oil," and this name took well with the patients.

The onion smell of the oil naturally forms an objection to its use with many patients. This unpleasantness was overcome in a preparation made for me by Mr. Frank Rogers, chemist, of Oxford Street, where the bisulphide oil was so happily blended with the oils of lavender, lemon, and geranium that the liniment became quite an elegant compound without loss of efficacy as a curative agent.

I am, Sir yours truly,
John C. Thorowgood, M.D., L.R.C.P.
Bognor, August, 1902.

Literature.

INTERNATIONAL CLINICS. (*a*)

Each series of the "International Clinics" consists of four volumes, one of which is issued in April, July, October and January. The volume contains 300 pages, royal 8vo, and is complete in itself. The present volume contains a biographical sketch of Dr. Weir Mitchell, who in his "Hugh Wynne" tells the story of Arnold and of that true heart and brave soldier Andre; and a biography of Dr. John Wyeth, whose story of Nathan Radford Forrest is a brilliant record of that great general's campaigns. We also get the story of President McKinley's death, and we learn why the bullet was not found, neither at the operation or at the autopsy.

The medical papers in the number cover the whole field of medicine; they are not numerous, but they are helpful and suggestive, the work of writers who bring from the treasury of their knowledge things new and old, one and all throwing light on obscure points in practice. The practical character of the papers may be learned from such titles as "The Use of Opium," "Habitual Constipation," "Thyroid Poisoning," "The Treatment of Acne." We may just add that the book is beautifully illustrated by some thirty-two plates, and contains about an equal number of illustrations.

Medical News.

York Lunatic's Death.

A coroner's inquest has been opened into the circumstances attending the death of an inmate of Bootham Asylum, York. The deceased, a man, aged 35 years, fell into the hands of the police on June 27th, owing to violent conduct in a hotel. He was removed to the workhouse, and on the following morning was brought before the court and afterwards committed to the asylum. It appears he was very violent while at the police station, that a considerable amount of force was required to restrain him, and that he made no complaint of wound or injury. Dr. Grove, assistant medical officer, deposed that deceased, who suffered from acute mania, was very violent when admitted to the asylum, and that it was impossible for him to perform the usual physical examination. He noticed, however, that he had a black eye and a large lump on the right side of his head. When he examined him on July 6th he found his back reddened, especially on the upper and lower parts, numerous external abrasions, and evidence of fracture of ribs. Up to that date he required two attendants, and on certain days had to be confined in the padded room. On July 15th he was informed that deceased had lost three teeth, and on examination found three teeth missing from the front lower jaw. Six days later he was breathing heavily, and gradually sank next day. Mr. Reynolds, police surgeon, who certified him to be insane on June 28th, stated he made no physical examination. He made a post-mortem examination of his body, and in addition to external injuries found twelve fractured ribs, the ragged ends of which had penetrated the pleura, and empyema had set in. The lining membrane of the heart was inflamed, the kidneys and liver affected, and the brain showed meningitis. Death, in his opinion, was due to exhaustion from the injuries and combination of the causes named. Roughly speaking, he thought the injuries were about a fortnight old. The evidence is not very enlightening, but we are glad the matter will be thoroughly sifted by the reigning authorities. It is a regrettable fact that insane persons are regularly removed to asylums without being medically examined physically, with the result that many are sent to an asylum merely to die. Not only does this mean needless public expense but it increases the death-rate of our asylums, and detracts

---

(*a*) Poore on "Nervous Affections of the Hand and other Studies." London: Smith, Elder and Co.

(*a*) "International Clinics: a Quarterly Journal of Illustrated Clinical Lectures, and especially Prepared Articles." Edited by Henry W. Cattell, A.M., M.D., Phil., Penn. Volume I. Twelfth Series. Philadelphia and London: J. B. Lippincott and Co. 1902.

from the value of their statistics. This certainly should not be, and death, in many cases, is doubtless hastened by removal. We think it is most important, and the case in question confirms our opinion, for a physician who is called upon to certify a person to be of unsound mind, to make a thorough physical, as well as mental, examination before doing so, and satisfy himself that the person is in a fit state to be removed to an asylum. Allowance must be made, however, in the case before us for the man's violent condition, but at the same time it is a matter for regret that the asylum officials did not carry out a more thorough physical examination when he was admitted, and even more so that the police surgeon made no physical examination at all. The inquiry has been adjourned, and we shall watch with much interest its ultimate result.

The Royal College of Surgeons in Ireland and the Coronation.

The Royal College of Surgeons in Ireland have presented the following address to the King:—

To His Most Excellent Majesty Edward the Seventh of the United Kingdom of Great Britain and Ireland and of the British Dominions beyond the Seas, King, Defender of the Faith, and Emperor of India.

May it please your Gracious Majesty,—We, the President, Vice-President, and Council of the Royal College of Surgeons in Ireland, beg most respectfully to offer our loyal and cordial congratulations on the auspicious occasion of the Coronation of your Majesty and of Queen Alexandra as King and Queen of Great Britain and Ireland and of the Dominions beyond the Sea. We feel pride in being the subjects of a Sovereign who has ever been foremost in all works of charity and mercy for promoting the comfort and alleviating the suffering of humanity not only as exemplified by the life-long interest taken in hospital extension and efficiency, but also as instanced by such movements as the housing of the working classes, the Tuberculosis Congress and the Cancer Commission. We rejoice that the happy event of the Coronation should have an additional splendour conferred upon it by the declaration of peace in South Africa and the permanent extension of the Empire. We trust the time is not far distant when your Majesties will visit this country as Ireland's King and Queen, and we venture to express our confidence that in no part of the realm would there be a deeper feeling of gratification and welcome. As a Royal College of Surgeons we have for over a century been responsible for the training and education of a large number of surgeons who have served, not without distinction, in your Majesty's Navy and Army. We beg to assure your Majesty of our determination to maintain the loyal and dutiful relations with our Sovereign which has always characterised the Royal College of Surgeons in Ireland. We rejoice that your Majesty has recovered from your recent serious illness.—Signed on behalf of the Council,

Lambert H. Ormsby, President.
Arthur Chance, Vice-President.
Charles A. Cameron, Secretary.

Small-pox in London.

The steady decrease in the number of fresh admissions has been maintained during the past week, and the number of patients under treatment in the hospitals of the Metropolitan Asylums Board is now under two hundred.

The Ventilation of Yachts.

The question of adequate ventilation is one often overlooked by designers of yachts, in spite of the fact that any shortcoming in this respect necessarily detracts in great measure from the benefit to health associated with this delightful pastime. In the German Emperor's new racing yacht the circulation of air between decks has been secured by means of the well-known "Boyle" system of ventilation, which acts independently of variations of atmospheric temperature, and is not affected by rough weather. Being quite automatic it is not liable to get out of order, and on this account the method is gradually finding its way into use in the Navy and in the ships of the large ocean companies. In troop ships especially the need for efficient ventilation has made itself felt, and excellent results have followed the introduction of the "Boyle" system.

The Case of Dr. W. T. Law.

A meeting of friends and sympathisers will be held at the Holborn Restaurant, W.C., on Friday afternoon, August 29th. The chair will be taken at 5 p.m. by Sir William Selby Church, Bart., M.D., President of the Royal College of Physicians of London, when the presentation will be made to Dr. W. T. Law. In the meantime the fund will remain open for the reception of any further contributions. Cheques and postal orders should be made payable to the Law Fund, and crossed London and County Bank, Holborn, W.C., and sent to Dr. Paramore, 2, Gordon Square, W.C., who will gladly acknowledge the receipt of all donations, however small.

The Welsh Hospital in South Africa.

A suitable memorial to the memory of those who died in connection with the Welsh Hospital in South Africa has been placed in St. David's Cathedral at Milford. It reads as follows:—"The Welsh Hospital in South Africa. This tablet was placed in this Cathedral Church by the Committee of the Welsh Hospital in South Africa in memory of those members of the medical and nursing staff of the hospital who died for their country in the Boer war in the years 1900 and 1901—Professor William Hughes, M.B., F.R.C.S., Professor Thomas Jones, M.B., F.R.C.S., Herbert Davies, M.B., Thomas Richard Eames, Dresser; Marion Lloyd, Royal Red Cross Matron; Florence Louise Sage, Nursing-Sister. Gorphwysant."

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, August 9th, 1902, represent an annual rate of mortality of 21·2 in every 1,000 of the population; 65 infants died during the week, of whom 31 were under one year old; 18 deaths were caused by diseases of the circulatory system; 28 from diseases of the respiratory system; 28 deaths by measles; and 13 from diseases of the nervous system. In the Blackhall Place district, the Castle Street district, Grand Canal Street district, and Palmerston the death-rates were 32·9, 24·4, 24·6, and 26·9 respectively.

King Edward's Hospital Fund.

By the direction of the Prince of Wales a cheque for £460 has been forwarded to King Edward's Hospital Fund for London. This amount represents the net profit of the exhibition at the Imperial Institute of Colonial gifts and addresses received by the Prince and Princess of Wales during their recent tour.

The Late Dr. Pepper.

The remains of Dr. W. H. Pepper, of Birmingham, who met his death whilst on a yachting cruise on the Norfolk Broads, have been quietly interred at Acle, the scene of the sad disaster.

Pass Lists.

Society of Apothecaries of London.

The following candidates have passed in:—

Surgery.—W. Ball (Section II.), S. Bentley (Sections I. and II.), A. E. Henton (Sections I. and II.), G. A. Jones (Sections I. and II.), J. D. Keir (Sections I. and II.), D. E. Lockwood (Section II.), A. R. McEnnery (Sections I. and II.).

Medicine.—W. Ball (Section II.), I. Griffith (Section I.), A. T. Harvey, A. R. McEnnery (Sections I. and II.), E. H. Noney (Sections I. and II.), C. H. Osmond (Section II.), C. M. Woods (Section II.).

Forensic Medicine.—W. C. P. Bremner, A. R. McEnnery, E. H. Noney, H. F. B. Roberts, F. C. Whitmore.

Midwifery.—W. Ball, G. J. Humphreys, A. R. McEnnery, J. P. Nettell, E. H. Noney, S. Northwood, H. F. B. Roberts.

The diploma of the Society was granted to the following, entitling them to practise medicine, surgery, and midwifery:—W. Ball, G. A. Jones, D. E. Lockwood, A. R. McEnnery, H. F. B. Roberts, and C. M. Woods.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

SPOTTED FEVER.

Montana.—The disease popularly known as "spotted fever" is probably enanthematous typhus, but, as the name implies, the diagnosis is made by inexperienced persons, and may cover measles, or, indeed, any febrile eruptive affections.

Status.—It is stated that 75 per cent. of female inmates of prisons, a large proportion of whom are under twenty years of age, are of intemperate habits, and the effect of a term of imprisonment in no way prevents them resuming their habits when liberated. This fact does not prove much in the absence of any aural training during the period of reclusion, and reform cannot be expected unless these prisoners, on liberation, are taken in hand and provided with employment.

A MEDICAL HIVE.

A large office building in Chicago, says the N. Y. *Medical Record*, is occupied in its entirety by medical men and dentists, there being no less than 222 physicians and thirty-six dentists under the one roof. This well-nigh represents the Cavendish Square district under one roof.

C. O. A.—It was Trousseau who directed attention to the significance of unilateral deafness in association with typhoid fever—when bilateral he considered the prognosis to be favourable. His observations on this point do not appear to have been confirmed by independent clinical research, and in any case affections of the ear are really very exceptional in this connection.

Verax.—The expression to which you take exception was a quotation, and in no way represents the view taken by the Editor. The omission of inverted commas explains the mistake, although the context makes matters quite clear.

DISTRIBUTION OF PHYSICIANS.

Statistics recently published show that the town containing relatively the largest number of physicians in the United Kingdom is Clifton, with 36·8 per 10,000 of population; Dublin has 13·8, Glasgow 12·8, London 12, Sheffield 5.

Appointments.

Finn, P. T., L.R.C.P.Edin., L.R C.S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Ashwick District of Somersetshire.

Harding, Norman E., M.B., Ch.B.Edin., Second House Surgeon to the East Suffolk and Ipswich Hospital.

Harvey, Alfred, M.B.Lond., M.R.C.S., L.S.A., Medical Officer to the Southmead Workhouse by the Barton Regis Board of Guardians.

Hoole, John, M.R.C.S.Eng., L.S.A.Lond., Medical Officer and Public Vaccinator to the Hartington District of the Ashbourne Union.

Jenkins, George Harrison, L.R.C.P., L.R.C.S.Edin., L F.P.S. Glasg., Medical Officerof Health for the Usk (Mon.) District Council.

Johnson, Henry Sandford, M.R.C.P.Irel., L.F.P.S.Glasg., Medical Officer of Health for the Ashburton (Devon) District Council.

Lapage, C. P., M.B., Ch.B., House Surgeon to the Manchester Royal Infirmary.

Macmillan, J. I., M.B., M.S.Glasg., Certifying Surgeon under the Factory Act for the Laurencekirk District.

Paton, Leslie, B.A., M.B., B.C.Camb., F.R.C.S.Eng., Assistant Ophthalmic Surgeon to St. Mary's Hospital, Paddington.

Sadler, E. A., M.D.Lond., Medical Officer of Health to the Ashbourne District Council.

Stewart, J. H., M.B., B.Sc., R.U.I, Certifying Surgeon under the Factory Act for the Cruden District of Aberdeenshire.

Sweeny, W. J., M.B., B.Ch., B.A.O., R.U.I., Deputy Medical Officer for the Thornbury District and Workhouse.

Vacancies.

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum and furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Cancer Hospital, London.—Pathologist. Salary £250 per annum. Applications to the Secretary at the Hospital, Fulham Road, S.W.

City (Fever) Hospital, Aberdeen.—Resident Physician. Salary £100, with board and rooms. Applications to the Medical Officer of Health, City Buildings, Aberdeen.

City of Liverpool Infectious Diseases Hospital.—Assistant Resident Medical Officer. Salary of £120 per annum, with board, washing, and lodging at the Hospital. Applications to the Chairman.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £130, with board, furnished apartments, laundry, &c. Applications immediately to the Medical Superintendent.

County of Lanark.—District of the Middle Ward.—Resident Physician. Salary £140 per annum with board, &c. Applications to J. B. Ferguson, District Clerk, District Offices, Hamilton.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100 to commence, with board, residence, and washing. Applications to Secretary.

Jenner Institute of Preventive Medicine.—Assistant Bacteriologist. Salary £200, with furnished rooms. Applications to the Secretary, Jenner Institute, Chelsea Gardens, S.W.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum. Furnished apartments, attendance, light, and fuel are provided. Applications to Secretary, Mr. J. Preston, Journal Chambers, Nottingham.

Parish of Birmingham.—Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with furnished apartments, rations, coal, gas, laundry, and attendance. Applications to Walter Bowen, Clerk to the Guardians, Parish Offices, Edmund Street.

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £120 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

St. Giles, Camberwell.—Assistant Medical Officer. Salary £120 per annum, with furnished apartments outside the Workhouse, and an allowance of £1 1s. weekly in lieu of board and washing. Applications to Charles S. Stevens. Clerk to the Guardians, Guardians' Offices, 29, Peckham Road, S.E.

Tadcaster, Goole, Riccall, and Selby Rural Districts, and Selby Urban District.—Medical Officer of Health. Salary £120 per annum. Applications to E. Townend, Clerk to the Joint Committee, 1, Abbey Place, Selby.

Urlingford Dispensary District and Workhouse Hospital.—Temporary Medical Officer. Salary £3 3s. per week for the former, and £1 1s. per week for the latter office. Immediate application to M. P. Dowling, Clerk of Union. (See Advt.)

Weston-super-Mare Hospital and Dispensary.—Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to the Honorary Secretary.

Birth.

Snell.—On Aug 16th, at Glenshee Lodge, Wandsworth Common, S.W., the wife of Sidney H. Snell, M.D.Lond., of a son.

Marriage.

Phillips-Jenkin.—On Aug. 14th, at Landewednack Church, the Lizard. Cornwall, Harry Harding Phillips, M.R.C.S.Eng., L.R.C.P.Lond., of Hamilton House, Penge, to Frances Mary, third daughter of Pearse Jenkin, of Trewirgie, Redruth, and Tregullus House, the Lizard.

Deaths.

Gasquet.—On Aug. 13th, at No. 1, College Gate, Brighton, Joseph Raymond Gasquet, M.D., aged 64 years.

Tuxford.—On Aug. 14th, at 51, High Street, Boston, James Edward Tuxford, M.R.C.S., L.R.C.P., &c., of pneumonia, after a few days' illness.

Wyman.—On Aug. 16th, at Red Brae, Putney Hill, S.W., William Sanderson Wyman, M.D., F.R.C.S., L.S.A., in his 71st year.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m.—Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. Northern Central, 2.30 p.m.—West London, 2.30 p.m.—London Throat, 9.30 a m.—Royal Free, 2 p.m

TUESDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—Guy's, 1.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m.—West London, 2.30 p.m.—University College, 2 p.m.—St. George's, 1 p.m.—St. Mary's, 1 p.m.—St. Mark's, 2.30 p.m.—Cancer, 2 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—Royal Ear, 3 p.m.—Samaritan 9.30 a.m. and 2.30 p.m.—Throat (Golden Square), 9.30 a.m.—Soho Square, 2 p.m.

WEDNESDAYS.—St. Bartholomew's, 1.30 p.m.—University College, 2 p.m.—Royal Free, 2 p.m.—Middlesex, 1.30 p.m.—Charing Cross, 3 p.m.—St. Thomas's, 2 p.m.—London, 2 p.m.—King's College, 2 p.m.—St. George's, (Ophthalmic) 1 p.m.—St. Mary's, 2 p.m.—National Orthopædic, 10 a.m.—St. Peter's, 2 p.m.—Samaritan, 9.30 a.m. and 2 30 p.m.—Gt. Original Communications.

CHRONIC PROGRESSIVE DEAFNESS. (*a*)

By MAYO COLLIER, M.S.LOND., F.R.C.S.ENG.,
Senior Surgeon to the North-West London Hospital, Ex-President of the British Laryngological, Rhinological, and Otological Association, &c.

THE affection I propose to deal with more particularly in this communication is the form of deafness that occurs quite insidiously without warning, without pain or previous discomfort of any kind, and only becomes apparent to the individual when a marked impairment of hearing has taken place.

I propose to call this form of deafness, in contradistinction to cases of deafness secondary to ear diseases, "chronic progressive deafness."

The terms chronic middle ear disease, chronic middle ear catarrh, chronic non-suppurative disease of the middle ear, chronic sclerosis, include certain conditions, the result of previous catarrh, suppuration, congestion, injury or other morbid states in and about the middle ear.

It is a matter of common knowledge that a very large number of the inhabitants of this country, America, and other temperate and moist regions, are afflicted with a form of painless, slowly increasing deafness, for which at present, as far as I am able to state, no adequate reason, cause or explanation has been forthcoming by those whose special duty it is to make a study of this subject. For this slow, gradual, painless, chronic form of deafness I propose to assign the adjectives "chronic" and "progressive."

I am chiefly concerned to-day in endeavouring to more clearly define the cause of this slow, chronic, progressive form of deafness. It is only by finding out the causes of diseases that we are in a position to prevent or formulate the most suitable and appropriate treatment with a view to cure them. In the words of Bacon—"Vere scire est per causas scire."

Now, Sir, one naturally turns first to the works and writings of one's own countrymen for instruction, information and advice on most subjects. But I must candidly confess that on the subject of the ætiology of chronic progressive deafness, or indeed the larger and more comprehensive class of disease known as chronic sclerosis, little or no assistance can be obtained from the writings of one's own countrymen. Most of the text-books are singularly silent on this subject, and those that are not silent are not instructive.

If we turn to the writings of our American *confrères* we find them singularly rich with thoughts and suggestions on this very subject.

In a paper dealing more or less with this subject, published in the "Transactions of the Meeting of the British Medical Association at Cheltenham" last year, I ventured to quote some statistics collected and got together by Dr. Sam Seaton, of New York.

Burnett's "System of Diseases of the Throat, Nose, and Ear" may be unknown to some of us present, but at one time it was the foremost work on the subject, and was written and collated by the foremost men of the period.

Dr. Sam Seaton, of New York, was one of these. In endeavouring to elucidate the subject he says: "The ages of the subjects of this affection range between 5 and 80." Next, "That most of the cases develop between the ages of 20 and 30, and that the next most prolific decade is between the ages of 10 and 20."

This is evidently, then, not a disease of Anno Domini.

Between 10 and 30 is not the period of life when degenerative changes take place, and is not the most prolific time for gouty and rheumatic deposits to take place in the fibrous tissues of the body. This is the period of life when the functional activity of the body is greatest, and when the various vasomotor changes incident to catarrh are most likely to take place.

He then goes on to say, "The next point of interest is the extraordinary frequency of this affection. One quarter to one-third of all ear affections are of this nature, and probably a larger proportion, from the fact that only the advanced cases apply for relief. The absolute frequency as measured by the number of cases of the total population is very great."

"The majority of people have some involvement of the middle ear, and a majority of those so afflicted are cases of chronic sclerosis," or, as I would prefer to designate them, chronic progressive deafness.

Dr. Sam Seaton further says:—"Chronic or adhesive inflammation of the tympanum is an affection most prevalent in the damper portions of the temperate zone, where sudden changes of temperature associated with moisture of the atmosphere are liable to occur."

Now let us turn to Dr. Dench, of New York, one of the foremost modern authorities on the subject. Quoting from De Schweinitz and Randall's work on "Disease of the Eye, Ear, Throat and Nose," published in 1899, Dr. Dench says:—"The term chronic catarrh has in my opinion led to a very general misunderstanding among the medical profession in regard to the changes that take place in the middle ear in the disease under consideration. It would be much better to designate this affection as chronic non-suppurative disease of the middle ear. The word catarrh is so universally associated with some affection of the upper air tract that both the profession and laity have come to look upon a chronic catarrhal otitis media (so-called) [Collier] as the result of an extension of an inflammatory process from the nose and naso-pharynx into the tympanum by contiguity of structure.

(*a*) Abstract of a paper presented to the Manchester meeting of the British Medical Association, July-August, 1902.

"Catarrh is not a disease but a symptom, and from its derivation means a discharge.

"It may, therefore, result from various local lesions, and the idea so commonly entertained that catarrhal inflammation of the middle ear is always due to the extension of an inflammatory process from the nose and naso-pharynx is entirely unwarranted. *The influence exerted by an affection of the nose or naso-pharynx is usually purely mechanical.*"

"Thus in the case of adenoid vegetations within the naso-pharynx, the middle ear may suffer either from the direct pressure of the lymphatic tissue upon the mouth of the Eustachian tubes, causing a rarefication of the air within the tympanum, or this lymphatic tissue may interfere with the return circulation from the tympanum, thus causing a dilatation of the veins within this cavity and consequent congestion of the lining membrane.

"The obstructive lesions of the nose and naso-pharynx cause chronic middle ear disease, chiefly through their influence upon the tympanic blood current."

This quotation, published in 1899, is a pretty fair summary of the position I have taken up now for many years in reference to the ætiology of chronic progressive deafness.

Then what further is the position that I take up in reference to the ætiology of this affection?

I believe that in a chronic or neglected cold in the head you have the most fertile cause of chronic progressive deafness.

I am not alone in this contention. This is the general belief now in America.

Dr. Dench agrees with me that the influence exerted by any disease of the nose or naso-pharynx is usually purely mechanical.

The purely mechanical partial obstruction of the Eustachian tube associated with a chronic nasal and post-nasal catarrh, means a diminished or impeded supply of air to the tympanum. This diminished or impeded supply of air is quite sufficient to account for all the pathological conditions and symptoms found in this form of middle ear disease. Singularly enough, in a work recently written by Professor Friedrich, Privat docent of the University of Leipzig, and translated by Dr. Holbrook Curtis, Consulting Surgeon to the New York Nose and Throat Hospital, the following passage occurs printed in italics:—"It follows, therefore, that a fall in the tympanic pressure occurs in all diseases in which the pharyngeal orifice of the Eustachian tube is occluded," and, quoting from Bezold, says:—"In the middle ear, as in all vascular air-containing cavities, the volume of air diminishes whenever free communication with the atmosphere is interrupted, because the oxygen enters into chemic combination with the blood, and the amount of CO_2 given up is not enough to compensate for the loss of volume."

"The pressure variations give rise to a series of clinical pictures which are included under the general term of acute and chronic middle ear catarrh, and have as their most prominent symptoms retraction of the tympanic membranes, a purely mechanical result of the increased pressure in the external auditory canal.

"In the otoscopic image this abnormal position and the curvature of the tympanic membrane find their expression in the absence of the cone of light from its normal situation; in the presence of irregular reflexes, in displacement of the handle of the malleus, which assumes a more horizontal position or eventually even disappears behind the posterior fold, and finally in a marked projection of the short process and handle of the malleus from the retracted membrane.

"The subjective symptoms are, diminished auditory acuity and tinnitus aurium; occasionally the patient complains of pain." The author then goes on to explain how the hyperæmia ex vacuo results in acute cases in hydrops ex vacuo.

A greater similarity between the above quotation and remarks published long since by myself could hardly exist. It is gratifying to find that the conclusions I have long since arrived at are at last dawning upon our more enlightened Continental *confrères*. I am not without hope that our more conservative countrymen may soon be persuaded to acknowledge the correctness of these views and practise them. Then, and then only, will chronic progressive deafness cease to be an opprobrium to the profession of medicine.

It is to be hoped that the highly educated twentieth century practitioner will now recognise that a catarrh of the upper respiratory tract is not to be looked upon as "only a cold," but that it may be a pathological condition fraught with danger not only to the functions of hearing, speech and respiration, but even ultimately may threaten the very life of the subject by the secondary results of bronchitis, pneumonia and suppuration in and about the accessory cavities of the nose.

EXPERIENCES IN THE EXTIRPATION OF TUBERCULOUS LYMPH GLANDS DURING THE LAST THIRTY YEARS, COMPRISING OVER 300 OPERATIONS. (a)

By RUSHTON PARKER, M.B., B.S., F.R.C.S.,
Professor of Surgery in University College, Liverpool; Surgeon to the Liverpool Royal Infirmary; President of the Liverpool Medical Institution.

Having seen Prof. Billroth perform excision of enlarged tuberculous glands in 1871, the author commenced the practice himself in 1872, in which year he performed 28 excisions on 18 young persons, 6 male and 12 female, from 7 to 15 years old; publishing an account in the Liverpool and Manchester Medical and Surgical Reports, issued early in 1873.

During the thirty years that have elapsed he had performed the operation 318 times on 224 persons, 93 male and 131 female, aged from 1½ to 60 years.

The situations operated on were the axilla (15 times), the inguinal glands (10 times), the femoral (once), and the neck in the rest.

The writings referred to were those of Dr. Clifford Allbutt (International Med. Congress Reports, 1881, Mr. T. Pridgin Teale (*Brit. Med Jour.*, 1893), Messrs. W. K. Treves and Bertram Thornton (*Lancet*, 1888-1889), and Dr. Keen, of Philadelphia (*Brit. Med. Jour.*, 1894, p. 160).

The earliest published operations after his own in 1872 were those of Mr. Teale (1878 to 1881 and onwards), and there are some from from Mr. W. K. Treves (1884 to 1887) who said he had then practised the operation for years (*Lancet*, 1888, Vol. I., p. 105).

All these gentlemen agree with the writer in regarding other treatment than extirpation to be trifling waste of time, and have been at no small pains to get thoroughly rid of the disease, which is mainly quite local, and generally amenable to radical cure in this way.

The writer has carried extirpation to considerable lengths, and has performed prolonged and difficult operations, sometimes several in the same person, in very advanced and extensive instances of the disease, often in persons seriously enfeebled, with such manifest advantage as to result in total restoration of health and strength, as well as in eradication of tuberculous disease. Instances of this kind were specified by the author.

(a) Abstract of paper read before British Medical Association Meeting at Manchester, July-August, 1902.

Though the practice is widely accepted and freely adopted he considers that it should be universally impressed upon the profession as the only rational treatment, which should be applied with less delay than it often is, and thus diminish the proportion of advanced (which are frequently neglected) cases; in spite of attendant difficulties; and furthermore should be more readily undertaken by operators in cases which have reached advanced stages.

Note.—The day following the reading of this paper the author was informed, in Manchester, by Mr. F. C. Madden, Professor of Surgery in Cairo, that very great numbers of such cases are prevalent in Egypt, and was made aware of a paper on the subject by Mr. H. M. W. Milton, of Cairo, in the *St. Thomas' Hospital Reports* of a few years ago, dealing with a thousand operations of the kind. This paper the author read a day or two after, and found in it a confirmation of his own views and practice, from an experience altogether surpassing that which seems to fall to the lot of European and American surgeons.

A CASE OF TUBERCULOSIS OF THE RIGHT KNEE-JOINT IN A CHILD OF FOUR YEARS OF AGE, CURED BY MONOSITEISM. (a)

By A. RABAGLIATI, M.D., F.R.C.S.Ed.,
Honorary Gynæcologist, Bradford Royal Infirmary; late Senior Honorary Surgeon; Consulting Surgeon Children's Hospital.

Mr. President and Gentlemen,—The facts of the following case of tuberculous disease of the right knee-joint and of the lower part of the femur on that side are comparatively few, and may therefore be put into short compass, although the treatment of the case has extended over a long period of time. M. L. M., a child, æt. 4, was admitted in-patient into the Bradford Children's Hospital on April 23rd, 1901. The house-surgeon's notes on admission are to the following effect:—"Right knee is very much swollen. Skin is glazed over the surface. Over the external condyle of the femur the skin is red. At this point there is fluctuation; on palpation the joint generally has a doughy thickened consistence. The bones are slightly broadened. The right knee measures 11¾ ins., or 29½ cm. in circumference. Left knee measured 23 cm. Right thigh and leg are wasted."

April 27th.—Knee abscess opened above the joint, and the pus evacuated, and a quantity of soft gelatinous material cleared out by sharp spoon. Child's weight on May 27th, 1901, the first occasion on which it was recorded, was 28½ lbs. The temperature was as a rule sub-normal, varying from 97° to 98° F. for the most part, and not even reaching 99° F. after the operation referred to. The pulse was variable in rate. Thus on May 14th, 1901, it was in the morning 96, in the evening 96. On May 15th it was 80 and 100 respectively. On May 16th it was 100 in the morning and 84 in the evening. On May 27th, with a morning and evening temperature of 97° F., the pulse rate was 66 in the morning and 52 in the evening. These conditions may be described as conditions of depression on the whole, with some slight tendency towards reactionary elevation as regards the pulse-rate. At this time, also, the little patient was very much constipated. Thus, on May 14th, 15th, 18th, and 21st she required to have, or at least did have, pul. glycyrrhizæ Co administered. I may say here, in reference to this point, that for eight months past, since November 30th, 1901, to the end of July, 1902, no aperient has been administered, nor has any been required, the bowels acting with daily regularity. I should, however, say further, that while the child had aperients administered constantly from the time of admission, on April 23rd, till June 19th, 1901, she required none from that date till July 26th, 1901, after which she required no more till the month of November of that year. She had an aperient administered on November 6th, 1901, on the 7th, on the 12th, on the 18th, 24th, 28th, and 30th, and none since then. I draw attention, therefore, at this point, to the fact that whatever else has happened to the child during the time in which she has been subjected to this treatment, the action of the bowels has become perfectly regulated during its course.

I do not wish to weary you with details, and happily there is no need to do so, although the case has been under treatment for over a year; but in case there may be sufficient interest to follow it, I insert here a statement of the child's pulse-rate, temperature and weight on the 1st of each month, from her admission to the present time.

1901.	Pulse-rate.		Temperature.		Weight.
Month.	Morning.	Evening.	Morning.	Evening.	Lbs.
June 1 ...	76	72	97·6°	97·8°	28½
July 1 ...	116	108	97·4	98·4	30½
Aug. 1 ...	64	120	99 6	100	30¼
Sept. 1 ...	96	100	97	98 8	30¼
Oct. 1 ...	76	96	97·4	98 6	30½
Nov. 1 ...	92	82	98	98·2	29
Dec. 1 ...	110	100	97·8	98·8	30
1902.					
Jan. 1 ...	90	112	97	97	30⅞
Feb. 1 ...	84	112	97·6	97·8	34¾
Mar. 1 ...	76	112	97	99	33⅞
Apr. 1 ...	96	88	97·2	98·6	33½
May 1 ...	112	118	97	98·4	scales out of order
June 1 ...	84	96	97·4	98·2	35⅛
July 1 ...	86	90	97·8	98·2	87⅞

On looking at these records one may say of them briefly: (1) The temperature, though occasionally up above normal, has generally been subnormal, especially in the mornings. (Subnormality of the morning temperature is, however, a very common condition, commoner than is usually supposed.) (2) The pulse has generally been rather quick. And (3) there has been on the whole an increase of the bodily weight. This increase has not, however, been continuous, but has been intermittent in accordance with what appears to me to be the rule in the phenomena of the human body, and not only in it, indeed, but also in all, or nearly all, the other phenomena observed on this planet. The weight has risen and fallen, but on the whole has kept rising like a rising tide, and there has been since admission, fifteen months ago, a gain in weight of about 9 lbs. This is about the normal increase in a child of four to five years old, so that in this respect also the behaviour of the growing organism has shown a close approximation to the normal.

As regards surgical interference, there has not been a great deal. As has been said, pus (of a somewhat cheesy character), along with some gelatinous material, were cleared out soon after the patient's admission to hospital. The limb was kept quiet and under extension till July 30th, 1901, when the weight was left off. On December 11th, 1901, I opened the joint in front aseptically, to see if there was any suppuration in it, but I found none; only a doughy swollen, thickened synovial membrane, a small portion of which I removed. The wound so made healed rapidly by first intention; but the original wound over the external condyle of the femur was not quite healed till March 2nd, 1902. On April 2nd the splint, a poroplastic one, was left off, and the child was encouraged to use the limb in bed, and on May 10th to get up. On July 23rd the diseased knee measured 25 cm., against 29½ on admission, the sound one measuring 23 cm. in circumference. The last measurements are 25 cm. and 24 cm. respectively.

At the present time the child has no pain and no tenderness on pressure or tapping the joint or the scar, a great contrast to the irritable inflamed tender condition she was in on admission, when she cried painfully when touched. There is a considerable amount of limitation of movement in the antero-posterior action of the joint, combined with (what sounds a little incompatible but is not) too much lateral and unnatural movement from side to side. But the patient gets about very well now. At first on getting up she used to push a chair in front of her, getting about in that way. After that she pushed the weak limb in front of her, and brought the left up behind it. Now she is somewhat lame, but gets about very rapidly and without pain. Now that the knee has recovered much of its natural shape it is seen that she is somewhat knock-kneed on the right side, and no doubt this condition has acted as a predisposing and contributory cause of the joint disease.

(a) A Paper prepared for the Children's Section at the Annual Meeting of the British Medical Association, held in Manchester, July-August, 1902.

I now come to the central or most important point in this communication. From admission on April 23rd, 1901, till June 2, 1901, the patient had half a pint of milk at 8 a.m. and 4 and 8 p.m. with the same quantity of soup (beef tea, mutton-tea, chicken-tea, veal broth, or oxtail soup—it did not matter which) at 12 noon. It is easy to calculate the nutritive value of this diet. It amounts to about 450 grand calories daily, and is properly described as a restricted diet, or even a much restricted diet or an oligositeous diet. After June 2nd, 1901, the patient had her half-pint of milk in the morning at eight, and in the evening at six, and had a dinner at twelve noon, the same as the other children in the hospital; that is, a dinner of mixed diet, meat, potatoes, pudding; anything and everything that was going, variety being very properly studied in the housekeeping department of the Bradford Children's Hospital, as in other well-managed hospitals in the country. The gross weight of this dinner was found to be very steady. It has very rarely been as low as 1¾ lb. and not often so high as 2½ lbs., but day after day, for as long as ten days together, it has weighed 2¼ lbs. The weight has not differed very much from the dinner weight of other children in the hospital at the same age. It has not been any more than they have had, although the rule with the others has been that they had breakfast and tea in the usual way. At one period, I may say, in the history of the Bradford Children's Hospital, it was the custom to feed the children five times a day, viz., at six and nine a.m., twelve noon, dinner, and at 3 and 6 p.m. The other four meals consisted of bread and milk. The dinner consisted, as it does now, of a mixed fare, and, as bread was not excluded from it, the children had at that time bread five times a day. I think that that plan came to an end in 1899 for reasons to which no further reference need be made, but I may say that, to put it as mildly as possible, the children have not been any less healthy on a trissiteous *régime* than they used to be on a pentasiteous one, nor has there been any more epidemic disease among them—rather less I should say. The question whether we should look for the causes of epidemic disease in bad air, defective drainage, over-crowding and sanitary defects generally, so exclusively as we are at present doing, and whether we are justified in closing our eyes to the evil predisposition to epidemic disease due to kakositeism, as it has been termed, is a very important and interesting one, and I mention it here in order to hint that I am not at all satisfied that the prevailing opinions and customs on this point are well founded. It is certainly a fair question whether there would be as much epidemic disease among children in and out of hospitals as there is now if they were fed differently from the ways that obtain now, and whether, when or if epidemic disease does break out among them, the proper way to meet it and to prevent future epidemics might not be rather to alter the children's mode of living than to close hospitals to visitors and prevent the children's friends from coming to see them, as it is now so much the fashion to do.

I have called M. L. M.'s diet a monositeous one, that is, a dietary *régime* which consists of one meal a day. It is not quite that, of course, for patient has had a glass of milk in addition morning and evening. I suppose we may take it that, although milk varies much in constitution and nutritive value, a tumblerful of it affords 140 or 150 grand calories when its energy has been converted in the body into physiological heat. Besides these two very small amounts of food, I have relied for making the child's blood, maintaining her strength, repairing her tissues, healing her wounds, and increasing her growth and weight on the midday mixed meal which she has taken. As regards its nutritive value, I have had the different kinds of food which she has taken weighed and differentiated, and the following account has been given me of the food which M. L. M. took in a day. It has been taken over the average of a number of days, and may be considered an average sample. I have tried to convert it into calories, following, on the whole, Dr. Robert Hutchison's Food and the Principles of Dietetics; but much difference exists still in opinion between different authorities as to the calorie value of foods, and even between the views stated in different passages from the same author. No doubt different samples of the same food differ in calorie value. "Excepting meats," says Dr. R. Hutchison, quoting Bulletin 74 of the United States Department of Agriculture, "there is probably no one article of food which is liable to so wide a variation in its percentage composition as milk." Evidently other samples of food differ from one another also in the same particular. But following Hutchison on the whole, I have made these calculations. M. L. M.'s diet contained the following articles:—

Meat, 8 ozs., uncooked, equal to 118 calories; potatoes, 4 ozs. (R. H., p. 486 = 90 cs.), equal to 115 calories; bread, 2 ozs., and ½ oz. of flour, calculated as 1 oz. bread, making together, bread 3 ozs., equal to 200 calories; 1¼ pint of milk (R. H., p. 486), equal to 420 calories; sugar, a teaspoonful, say 4 grammes, equal to 16 calories; rice, a table spoonful, taken as ½ oz., or say 1 oz. bread, equal to 65 calories; total, 934 calories. Beefstock, 10 ozs., say 65 calories. As, according to Atwater, the diet of a child of three to five years of age should have 40 per cent. of the calorie value of that of a properly fed man, and as the said man ought to have 3,000 to 3,500 calories, 40 per cent. of that would be 1,200 to 1,400 calories, and M. L. M.'s diet, therefore, of 934 calories, or say, 1,000 calories must, from this point of view, be considered a starvation diet. But it has been nothing of the kind. A diet on which a child of four years grows in weight, improves in health, under which constipated bowels become regular, and a diseased knee recovers, cannot reasonably be considered a starvation diet; and I say that this case raises afresh the kind of consideration which for many years now has been forcing itself on my mind, viz., that the quantity of food necessary for life and health, for at least townspeople, is much less than our authorities suppose and state.

The low temperature or subnormal temperature which M. L. M. exhibited as a rule, especially in the mornings, is a very interesting phenomenon I think, and worthy of study. A subnormal temperature is a not uncommon phenomenon. In adults its presence precedes, often for years, the onset of chronic diseases like rheumatism, Bright's disease and cancer. I am not so familiar with it among children, but it may be induced, as may all, or nearly all, other alterations of functions in the body by opposite conditions, and among these conditions the quantity of food taken appears to me to be the most important. It is a condition of depression, and being so it is usually believed to be caused by too little food, and the remedy for it is, therefore, generally considered to be increase of the diet. No doubt if a person is starved to death over a long period of time the temperature falls before the end comes. But it does not seem to be generally recognised that too much food is also a potent and a frequent cause of depression of temperature. I believe, indeed, that the presence of a subnormal temperature is far oftener caused by too much food than by too little. Of course I need not say how wholly differently we shall be compelled to set about the attempt to rectify the condition and to raise the temperature, according as we take one or other view as to its causation. The man who believes it to be due to too little food, to oligositeism, will recommend an increase of food; while he who believes it to be due to plethora, or polysiteism, will restrict the diet. It is one of the most difficult things in the whole range of medical practice as generally conducted to raise a subnormal temperature to natural; and I do not myself doubt that the reason of this is that we have no clear ideas in our minds as to its causation. As I have said, I believe it is almost always due to a long course of taking too much food, and, therefore, that in the large majority of cases (practically all, for we very rarely have to deal with such a case, *e.g.*, as of men exposed in a boat after shipwreck for fifty days with, say, ten days' provisions on board; this case is very rare indeed in civil practice) we must treat it by restriction of the diet. I once raised a subnormal temperature of 96° in a man by inducing him to undergo a course of starvation or asiteism for twenty-eight days. At the end of that time his temperature had risen to normal. If you attempt to raise a subnormal temperature caused by polysiteism by increasing the diet you cannot succeed. And what you do do is to induce a set of feverish attacks, when the temperature rises much above normal, settling down again after recovery into the subnormal temperature, which your efforts were directed to rectify. Let me set down here what seems to be the law as to the relation between the action of stimulus and the presence of function in organisation. I am thinking of food as the stimulus for the moment, of temperature as the function, and am proceeding to generalise.

1. In the absence of stimulus there is no function. (If organs are not supplied with nutriment they cease to act.)

2. In the presence of too much stimulus there is also absence of function. (If organs are supplied with too much nutriment they cease to act.)

3. In the presence of moderate stimulus there is normal function. (If organs are supplied with their proper amount of nutriment, neither too much nor too little, function is normal or natural.) These are very different propositions, allow me to say, from the statement that might have been made that, for example, absence of function is *caused* by absence of stimulus. I do not think we are entitled to say the latter. What we are entitled to say is that absence of function and absence of stimulus are co-ordinated and co-related. We are not entitled to say which is first—which is the cause of the other—at least, not till after a long philosophical inquiry very interesting, no doubt, to some minds, perhaps to all, but to enter on which as it would lead us very far on the present occasion, there is no time nor opportunity for. Let me just say in this connection that there are three possible views of the nexus which may be stated thus: Either (1) the thing is the cause of the thought, or (2) the thought is the cause of the thing, or (3) the thought is the thing. We may each of us have our own idea which of these possibilities contains the proper answer to our question, but happily we are not called on to state it here any more than we are called on to answer the question whether the hen or the egg was first. Suffice it to say that each follows each in invariable sequence, that they are co-ordinated and co-related, and might even be successive effects of a common cause.

These propositions appear to me to be translatable into all and every function of the body. Mark Twain's shipwrecked men who were forty-three days in the boat with ten days' provisions, and who were saved as by a miracle at the end, had had no action of the bowels, for in some cases twenty and thirty days, and in one case it was forty-four days before the bowels acted after the man had been saved. In the absence of stimulus there was no function. And there were two reasons for this: First, there was nothing to pass, the men were entirely empty; second, there was no strength to void it if there had been. The men were at the point of death from starvation, and weak in proportion. But by far the commonest cause of constipation is too frequent and too abundant feeding; so that if a person is constipated on four meals a day he should try three for three months; but if that does not put him right, especially if he alters the sorts of foods he takes at the same time, he ought to try two meals a day for three months, when he will in most cases become regular. But if he does not do so, he ought to try the effects of one daily meal, when, as in M. L. M.'s case, he will nearly always become regular. In the case of constipation being caused by starvation, the function is checked by too little. But in the case of constipation being caused by too frequent and too abundant feeding, the function is plugged or clogged by too much. I need hardly refer to the analogous case in business. Business comes to a standstill in two conditions; first, when there are no stocks to buy or sell, for in the absence of the stimulus of stocks the business function of the commercial organism ceases. But secondly, business comes to a standstill when stocks are too abundant and too heavy, because in such condition traders are afraid to buy and sell, lest, instead of making a profit they should sustain a loss. Therefore the presence of too much stimulus also clogs the function of the commercial organism. Lastly, when stocks are normal, proper, and neither too light nor too heavy, business goes on merrily and in a normal manner, for in the presence of a normal amount of stimulus the business function of the commercial organism becomes normal, with a gentle up and down movement of more or less, but with no depression of panic and no feverish excitement boom. But just as the business expert called in to advise the community how to act in the case of business being clogged by too much would be insane if he advised them to make more and heavier stocks, and ought, on the other hand, rather to advise them to use up what they had before they proceeded to manufacture more, so the doctor must be very careful what advice he gives about food ordered to meet a bodily depression which may be caused by too much. On the other hand, the depression of trade caused by the absence of stocks must be met by the advice to make stocks, to be industrious and to be active; and the depression due to direct starvation must be rectified by cautious increase of the diet. I think there are signs that M. L. M.'s subnormal temperature is in course of being elevated to normal, but the long length of time during which it has remained so low makes me ask myself, I must confess, whether even her one meal a day is not yet a little too much for her. This subject is intensely interesting, but I cannot dwell longer on it, and so will only say that the three propositions I have laid down seem to me to be true of all functions whatever, of sleep, of respiration, of cardiac action, of the action of the genito-urinary function, the general paradoxical statement holding true that absence of function may be induced by opposite conditions. There are other paradoxes with which we have to come in relation also in the practice of medicine, but I do not even mention them here; neither shall I be tempted to dwell any longer on considerations which I confess are very fascinating to me, but might lead us very far away and take up more time than we have at our disposal. The fundamental principles of medical practice are involved here.

In conclusion, gentlemen, let me invite you to reflect upon the case of a growing child suffering from a tuberculous or wasting disease, and who has been successfully treated not by increase but by restriction of her diet. An ounce of fact is worth tons of theory, but he will be the best interpreter of nature whose theory harmonises best with his facts. Restriction of her diet has resulted in the course of a year and a quarter in perfect regulation of the action of the child's bowels, in normal growth and increase of weight, from 28½ lbs. to about 37 lbs., and in the complete cure of a tuberculous suppuration and necrosis of the lower end of the femur, and disease of the knee-joint. It has not yet elevated her temperature to natural, nor has it succeeded in preventing too great inequalities in the range of the temperature readings between night and morning; neither has it yet lowered the pulse-rate to natural. But I think it is in course of effecting both of these tasks, and I look forward hopefully to being able to effect both of these achievements in the course of, say, another year or so.

I am strongly tempted to say a word, in conclusion, on tuberculosis in general. If tuberculosis be admitted to be an inflammatory disease (an inflammation) accompanied or associated with the growth of the tubercle bacillus in the tissues or blood, it is quite evident that we have two factors demanding consideration, viz., first, the state of the tissues which harbour the micro-organism; and secondly, the micro-organism which is harboured. In other words, both the soil and the seed demand consideration. Now, of the two, I incline to consider the former much the more important, and the idea which impresses itself on my mind (to be further developed on a future occasion) is that the long-continued inflammation which attracts the tubercle bacillus (it does not, of course, *create* it) is itself a consequence of long-continued irritation of some sort; and more precisely that it is very often the consequence of the long-continued irritation of wrong feeding (malnutrition), and that, still further to particularise, it is far most frequently the consequence not of under-feeding, but over-feeding. How very important this point of view is, and how far-reaching its effects on treatment, may rise before the imagination, but cannot be entered on, much less dealt with, now.

Medico-Chirurgical Notes.

By GEORGE FOY, M.D., F.R.C.S.,
Surgeon to the Drumcondra Hospital, Dublin

BILOCULAR STOMACH.

Among congenital diseases of the stomach abnormal constriction of the body of the viscus and the occurrence of partitions abnormally dividing it are usually included, even in such a comparatively recent book as that of Ernest Ziegler.

Pathologists of the seventeenth and eighteenth centuries were content with describing the condition when found without advancing any hypothesis. Brinton in his classical monograph on abnormalities of the stomach refused to recognise them as congenital, and looked on them as acquired. This view received confirmation from Sutton sixty years afterwards, who in his Erasmus Wilson lectures pointed out that the abnormality is not a condition of fœtal life, neither is it to be considered a reversion to the herbivorous stomach, which is a highly specialised one. Sacculation occasionally occurs as a port-mortem change, and, as shown by Carl Rokitansky, said form of the anomaly is easy of recognition.

Although the disease is an unusual one a good many cases are scattered through the writings of the older pathologists, the most common form being constriction of the stomach, such as Dutton pictures in "Evolution and Disease." Of these the great majority occur in women; but that the male sex is not exempt from the disease is shown by the case recorded by Blasius. As might be suspected from his diligence in dissection and his accuracy of observation, Morgagni came on some cases of the abnormality and has put four such on record. His first case was that of a woman on whom he successfully performed Cæsarean section. Her "stomach was contracted almost in the middle of its length and swelled out on both sides, but less on the right, which part descended obliquely, the other being placed transversely." In his second case, "the stomach was contracted, and where it began to approach the antrum pylori it was still more contracted, so as to be in some measure divided into two cavities." His third case was marked by "contraction in the middle, so as to resemble the straightness of the pylorus." The fourth case was well marked, "the stomach appeared to be almost double, so suddenly was the cavity contracted before it came to the antrum pylori."

All the six cases referred to above were sacculated by a transverse contraction, by far the most common form of the abnormality.

An unique case is placed on record this year by M. Bouveret, which shows how difficult it is to diagnose some forms of the disease.

The patient, a woman, æt. 45, came under the care of M. Bouveret in 1877, complaining of a large tumour in her left hypochondrium. It extended from the spine of the ilium to the diaphragm, and was wholly confined to the left side. On examination it was found to be dull on percussion, and it gave the sensation of a huge cyst with greatly distended walls. The diagnosis of an hydatid cyst of the spleen was made, and as the tumour seemed on the point of bursting it was punctured with a Potain's trocar. Two litres of a brownish liquid, of an unusual quality for hydatid cyst, was drawn off; on comparison with some fluid vomited by the patient the resemblance was so close as to lead to the conviction that the stomach had been tapped. The operation gave her great relief, and she disappeared from M. Bouveret's clinic. In 1898 she came under the care of M. Bard, when an operation was proposed and refused. Dreading any surgical interference she left hospital on March 3rd, and on April 19th following, during a severe fit of vomiting, the tumour burst and the woman died. A post-mortem revealed a strange condition of dilatation of a bilocular stomach. The cardiac orifice and the cardiac enlargements occupied their normal positions, but the lower portion of the body of the stomach had become enormously distended, so as to fill the whole of the left side and press on all the surrounding viscera. The lesser curvature was normal in size and position, but the organ was divided into two cavities, a small superior one and a large inferior, separated by two thin, valve-like flaps, one attached to each extremity, right and left of the opening from the upper to the lower cavity. At the cardiac end the food or liquid entering the stomach flowed readily into the lower chamber, as blood from the auricle to the ventricle, but on trying to pass any fluid into the upper chamber from the lower the valve was raised and the small upper chamber shut off so that nothing could enter. In a similar way the duodenal extremity was shut off. Such was the pathological condition found.

It is noteworthy that after the stomach was punctured the patient was greatly relieved. She drank fluids and took food without vomiting and continued well until the lower cavity filled again.

There is little doubt that an operation would have not alone given relief, but have prolonged life, and if not cured the patient, it would, at all events made life tolerable.

Special Article.

IS SYPHILIS AN ANCIENT DISEASE?

The approach of the International Congress of Venereal Disease, which is to hold its meetings at Brussels in September, should form an incitement to all members of the medical profession to contribute—as far as abilities and opportunities allow—by advice and by action, to the removal of this, one of the foulest blots on the physical history, as it has been one of the foulest enemies of the physical welfare, of the whole human race. The historic mystery of its origin, and the secretive factor necessarily connected with individual infection, have specially contributed to its long residence among us. All students of the history of medicine—as all true members of the profession should be—are familiar with the old story that the "lues venerea" was imported by the crew of Columbus from Hayti, and was communicated to the French besiegers by the Spanish garrison of Naples in 1494, and thence rapidly dispersed throughout Europe. But it was only after thirty years had elapsed from the introduction of the "French evil" into Italy, and its baptism with the name of "Morbus Gallicus," that the idea of its importation from the recently discovered Western Continent appears to have found its way into print. During the first quarter of the sixteenth century—down to 1525, and, in some cases, later still—the various medical authorities who wrote on the subject offered a great many varieties indeed of theoretical and fanciful explanations of the origin of the new venereal plague. The catalogue of "causes" is a long and, somewhat gruesomely, amusing one; but the assertion of its growth from an American germ is conspicuously absent. Those of our readers who have some knowledge of the hopelessly entangled connection of medicine with mysticism, metaphysics, and theology, which prevailed during the scholastic centuries, are, of course prepared to grasp the central factor in the generation of the inspired confidence with which two of the most prominent and most learned physicians of that age announced their belief that the origin of the French disease was due to the close conjunction of the sun with Mercury, Jupiter and Saturn, which happened in the year 1483. As it so happened that the year in which the great initial epidemic of venereal disease spread over Italy was also one characterised by exceptionally heavy rains and inundations, the still more famous physician, Nicolaus Leonicenus, discarded the astrological theory of Corradino Gillini and Gaspare Torella, and advanced the (less elevated) meteorological one, that the outbreak of this foul disorder was really engendered by the excessive amount of moisture then existing in the heavens above, and in, as well as on, the earth beneath. The great reputation of this physician governed the opinions of many subsequent authorities. Manardi and Paracelsus both ascribed the origin of the new disease to the intercourse of a leprous man with a prostitute: the former knew of the case—the gentleman was a Valentian by birth; the evidence obtained by Paracelsus was similar, but the male partner in his case was of French nativity. The learned and—deservedly—famous Antonius Musa Brasavola, of Ferrara, informed the professional world that the original epidemic of the French evil spread from the person of a female camp-follower of the French army at the siege of Naples. She had suffered from an abscess at the mouth of the uterus. But a widely divergent explanation of the source was offered by Gabriel Fallopius of Modena, the celebrated anatomist and physician, whose name has become immortalised in connection with the human oviduct. He avers that the Spaniards at the time when they were hard pressed by their French besiegers, poisoned the wells from which the latter obtained their water-supply, and that the new epidemic arose from that cause alone. The celebrated physician of Pope Clement VIII., Andrea Cesalpino—one of the foremost claimants to the credit of the discovery of the circulation of the blood—tells us that he learned from those who were present at the siege of Naples, and the other operations of that campaign, that the disease really originated at the siege of Somma, a village of the Vesuvian territory. There was a great quantity of an excellent, and much coveted, Greek wine shut up there. One night the besieged Spanish garrison managed to effect their escape, leaving behind them the greater part of their wine—which they had previously mingled with the blood of the sick of San Lazaro. The French besiegers, on entering the place next day, with the usual pillaging instincts of "that dissipated nation," drank freely of the luscious wine—after which they soon developed venereal symptoms. The learned Bolognese physician, Leonardo Fioravanti, states that he was informed by the son of a person who had been sutler to the army of Alfonso, King of Naples, that when the meat supply began to run short on account of the prolongation of the war, this sutler supplied both camps with dressed human flesh instead. The unconscious cannibalism which followed the gruesome fraud so effected, was the immediate cause of the development of the Morbus Gallicus. Our own very famous Lord Chancellor Bacon quotes this story, as he does so many other "old wives' tales," with patronising credulity; and tells us, too, that the human flesh supplied on that memorable occasion was of men killed in Barbary, and which had been prepared and dressed after the manner of tunny fish.

A strange "conjunction" of events of thrilling historical importance it surely was, that Europe should have been almost simultaneously affected (and inflicted) by the conquest of a new enemy, the Turks; the discovery of a new continent, America; the infection of a new disease, syphilis; the introduction of a new art, more revolutionary and iconoclastic than any of its forerunners, printing; and the propagation of the new theological doctrines which collectively constituted the so-called "Reformation." Whether the "Morbus Gallicus" was really new to Europe, is a question which, as of course all our readers know, is even now very strongly contested. The descriptions of disease in the classical ages are generally rather vague; and lesions of the genital organs would, probably, be dealt with in less detail than others. But the public castigators of the type of Juvenal and Martial offer many very significant allusions. The lines of Catullus, in which he so mercilessly attacks the morals of Julius Cæsar are, certainly, very suggestive:

"—— *maculæ* pares utrisque
Urbana altera, et illa foramina,
Impressæ resident nec eluentur."

The great French geographer, André Thevet, informs us that the French evil was endemic in Africa, along the regions bordering the river Senegal. J. Bonzius, who was physician to the Dutch settlement in the East Indies, affirms that the same disease was endemic in Amboyna and the Moluccas. And Cleyer, the first physician of the Dutch colony in Java, tells us that the venereal contagion was a natural endemic product of that great island, and as common there as the quotidian ague. We are told by Herrera that Magellan and his crew—in the first circumnavigation of the globe—landed at Timor, an island of the Moluccan Archipelago, and there found a great number of the inhabitants affected with the "French disease," although previously unacquainted with Europeans of all nations! Astruc, the author of the classical work on "Lues Venerea," questioned Forneau on the subject, who had long lived among the Chinese, and who had investigated their customs and penetrated their secrets as only a French Jesuit can. He was told that the Chinese physicians believed that the disease had existed there from the earliest antiquity: the authors of their oldest books referred to it as an ancient disease. Then, turning our attention to the names of more sacred countries and persons, we find theological authorities of the greatest learning defending the opinion that the multiform cutaneous ills from which Job suffered were syphilitic lesions. So firmly was that idea rooted in the Italian mind at the time of the original outbreak of the Morbus Gallicus that we have the testimony of the contemporary author Fulgosio to the effect that, even from the beginning, some called it *Morbus Sancti Jobi*. Since then, other saintly names have been attached to the disorder: it has at various times been referred to as the disease of St. Mevius, of St. Roch, of St. Sementius. From the original historic locus of its development, it has also been called the "Morbus Neapolitanus"; and from the hypothetical Spanish-American importation, it received the compound epithet of "Scabies Hispanica." The racial antipathies of dirt-throwing patriots sometimes transferred the prevalent association to other nationalities, and replaced the French surname by that of the people whom they most detested. Thus it was sometimes called the "German disease," "Polish disease," "Turkish disease"—by the Turks, the "Christian disease," and so on. The name syphilis, which to the present day remains the *pons asinorum* of surgical etymologists, appears to have been first popularised, if not invented, by Fracastorio. Whether the loathsome plague was one of local West Indian origin, as has so often been maintained, or of cosmopolitan diffusion, which would seem more likely, it is one which owes its existence to impure contact, and is most assuredly preventable. Let us hope that the coming International Congress will formulate the best advice on the subject, and that its suggestions may be rapidly utilised throughout all civilised communities.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 23rd, 1902.

Chlorosis and Sudden Death.

Professor Hayem relates a case of sudden death of a patient affected with chlorosis and caused by obliteration of the pulmonary artery.

A patient, æt. 21, became chlorotic a short time after being "regular." Two years before her entry into the hospital she suffered from phlegmasia dolens in the left leg, and a year subsequently she complained of palpitation and considerable dyspnœa. When examined in the hospital she was found to have violent tachycardia, and complained of constant headache and showed all the usual signs of advanced chlorosis. Ten days after admission the patient had a violent emotion, and sitting up in bed gave one cry and fell back dead. The autopsy revealed complete obliteration of the pulmonary artery by clots of blood, of which some were ancient, adhering to the walls of the artery, and others recent. Examination of the heart proved that the clots had their origin in the heart, where similar ones were found.

MEDICAL TREATMENT OF GASTRIC ULCER.

The same author recommends the following treatment for gastric ulcer. First of all rest in bed and absolute rest of the stomach. As the gastric juice is only given out under the influence of food, the stomach should remain completely empty for several days. To ease the thirst, however, a little water may be given from time to time, or, better, some mineral water of alkaline properties. Alimentary enemas will replace the ingestion of food, consisting of two eggs, peptone, carbonate of soda, and a little salt. Three or four of these enemas are given daily. The period of suspension of food varies from five to twenty days. Large doses of subnitrate of bismuth are prescribed as a protective dressing to the ulcer, and revulsion over the epigastrium produced by hot applications.

The second stage of the treatment consists in the gradual administration of milk and alkaline water, and after a month or five weeks a mixed diet is allowed, and finally the milk is suppressed. At this moment, or third stage, Carlsbad waters will be found very useful.

RHEUMATISM.

According to Dr. Desplats, the juice of lemons is an excellent remedy for rheumatism, acute or chronic. He considerably relieved an old woman who suffered much from chronic rheumatism, and was almost a cripple from the malady. A similar success attended its administration for acute rheumatism in a young girl, while in three days he cured himself from erratic rheumatic pains. He advises two lemons daily to begin with, and increase gradually until the desired effect is obtained. He tried to substitute for the juice citric acid, but he found that the patients could not tolerate a sufficient amount of this acid. Dr. Vigues has the same high opinion of the efficacy of the juice of lemon, not only in rheumatism, but in gout. Although it did not cure a malady which is in itself incurable, it relieved the pain, and that was a great point. On the other hand it in no way disturbed the digestive functions nor did it produce anæmia.

WHOOPING-COUGH.

The treatment of whooping-cough is, as every one knows, more or less empiric. A list of the numerous agents recommended for that mysterious and spasmodic affection would fill a book, a fact which considerably diminishes the value of any one of them, and yet the list is far from being closed; it will, on the contrary, likely remain open till the end of all time. Professor Amat reports two cases considerably relieved by inhalation, at the moment of the attack, of iodide of ethyle, which relieves so promptly attacks of asthma. The children were two and a-half years and six months old respectively, and with attacks so frequent that they became almost emaciated. Under the influence of these inhalations the attacks began to diminish in number, and finally at the end of a fortnight they disappeared completely.

M. Mya prefers pyridine, which he so largely employed in the treatment of asthma. Twice a day he places a teaspoonful of the liquid on a plate and draws it near to the cradle or bed of the little patient. At the same time he prescribes a mixture containing bromide of potassium, strontium and bromide of ammonium in order to diminish the reflex excitability of the brain.

HÆMORRHAGE IN GASTRIC ULCER.

Ergotine, ʒj;
Galic acid, x grs.;
Syrup of turpentine, ʒiv;
Water, ℥v.
Chloride of calcium, ʒj;
Syrup of opium, ʒiv;
Water, ℥v.

A tablespoonful of one of these mixtures alternately every hour.

Germany.

BERLIN, August 23rd, 1902.

WOUNDS OF THE LIVER.

IN the Zeitsch. f. Chir., Dr. Grekow, of St. Petersburg, reported three cases treated by himself. In two the injury was in the left lobe, and in the right in the other case. The two first were sutured, and the last was packed. In all the cases the hæmorrhage was arrested completely and all recovered. The writer considers suture to be the normal treatment, and as such to be carried out in all cases in which the injury can be brought into the field of vision, and that this will be the case in all or nearly all injuries on the left lobe, on the free margin, and those on the anterior and under surfaces of the liver near the free margin. In all other cases the tampon should be employed, and valuable time should not be lost in trying to bring the wound into view.

In the same journal five cases of rupture of the liver are reported by Dr. Finkilstein. In all the wounds were subcutaneous, and caused by blunt force. One died a few minutes after admission into hospital before any attempt could be made to rescue the patient, and in the remaining four cases laparotomy was performed. One died one hour after operation and the remaining three recovered. In two of them, along with extreme anæmia, there was peritoneal irritation, so that a suspicion arose that the intestine was injured also; this proved not to be the case, however. The bleeding was arrested in all cases by tamponnade, and the author considers this to be the proper line of treatment in this class of injuries. The attempt to unite the bruised and broken down edges of the wound offers but little prospect of success, and the time consumed in it makes it dangerous. It is important when removing the tampon to do it gradually and piece by piece, and not to remove it too early.

R. Stintzing, of Jena, has an article on

PLEURITIS

in the *Deut. Klinik.* He recommends the retention of the old classification into dry and exudative pleurisy and the latter with sero-fibrinous, hæmorrhagic and purulent. It is generally a secondary disease, most frequently caused by disease in a neighbouring organ, and above all the lungs. It usually arises from extensive *per continuitatem* of the original process; transference by the lymph tracts is more rare and least frequent through the blood channels. Ordinary pleurisy is a great rarity. Ætiologically the following forms are to be noted:—

1. Tuberculous pleurisy the form most widely spread, embracing nearly one-half of all the cases. It appears as dry or exudative pleurisy; more rarely as empyema. Hæmorrhagic effusion form, a rare exception.

2. Metapneumonic pleurisy, the second in regard to frequency, commences simultaneously or in connection with pneumonia, and set up by the pneumonic diplococcus. It runs a course serous or purulent.

3. Rheumatic pleurisy the third in frequency. Cases are to be classed as rheumatic that occur in association with an attack of articular rheumatism; it is sero-fibrinous.

4. Syphilitic pleurisy is rare, runs a course as dry pleurisy, and belongs exclusively to the tertiary period.

5. The staphylo- and streptococcus pleurisies are mostly inflammation following influenza, diphtheria, typhoid, sepsis, &c.

There are also mixed infection, and, further, the bacterium coli in cases of pleurisy and perityphlitis. Pleurisies after cardiac and kidney troubles and cancer are secondary. Chills and injuries are favouring accessories to their onset. As regards treatment, the question of puncture is an important one. The three indications are the well-known ones: (1) The vital in acute pleurisy, with grave symptoms as regards cyanosis and breathing; (2) the extent of the exudation, leading to ineffective respiration and cardiac action with extensive dulness; (3) imperfect absorption of medium exudations. There is no common point of time for puncture; the most favourable will always depend on the individual case. If the exudation extends beyond the fourth rib behind the middle of the scapula the evacuation must be made without regard to time, and fever is not a contra-indication. With good diuresis puncture may be delayed, but with scanty urine of high specific gravity puncture should be resorted to. As regards the quantity to be left, all should be removed that comes freely and without aspiration, let the quantity be what it will, but as a rule 1½ litres will be enough to remove.

In hæmorrhagic pleurisy puncture should be delayed as long as possible, and not more than 500 ccm. should be removed at a time; frequent repetition is generally necessary. In old sero-fibrinous exudation aspiration is required, and it is desirable to repeat the puncture in various places and to be content at one sitting with removing what comes away without too much aspiratory force. Uusually the fifth and sixth intercostal spaces are the most suitable spots for puncture, and an exploratory puncture should always precede the more important one. In purulent exudation simple puncture is indicated in urgent cases as a preparatory measure, and in tuberculous empyema. Radical operations for empyema in advanced phthisis rarely recover or heal up, and here frequent punctures at intervals of eight to fourteen days, taking away not too much at one time, are better.

Austria.

[From our own Correspondent.]

Vienna, August 23rd, 1902.

Supra-Condyloid Fracture of Humerus.

At the "Deutscher Aerzte" in Prague, Hilgenreiner showed a man, æt. 61, who suffered from "flexional fractured humerus" from a fall without pain or disturbance of function, and it was not till eight days after the accident that he consulted a doctor in reference to the swelling of the arm which he attributed to the fall. Hilgenreiner recognised the fracture at once, but the absence of pain and functional disturbance led him to employ the Röntgen rays, which confirmed the diagnosis. He put the arm in splints for eight weeks without success, union being as defective at the end of that time as at the beginning of the treatment.

All treatment was then abandoned, as the patient had good use of the limb and no pain. The fracture was not angular but straight, and therefore there was no displacement. He attributed this functional phenomenon to a general condition of exalted hypalgesia which existed throughout the subject. This case he thought raised an important point in forensic medicine as to how far functional disturbance or pain can be produced by fractures. During the last five years he had observed in Wölfler's clinic twenty other cases presenting this remarkable phenomena when carefully tested, so that the case is not an entirely isolated one.

From a therapeutic point of view, the proper treatment would be extension, just as in dislocation of the epiphysis, with forced flexion of the elbow-joint. In this case he would not recommend such treatment, since it would entail confinement to bed, which might be positively injurious to a man of such active habits.

Rectal Carcinoma.

Schloffer showed a patient from whom he had removed the rectum, together with the uterus and adnexa, on account of the extensive area affected. The patient was at the present time perfectly healthy.

Gussenbauer opened a discussion on the histogeneses of carcinoma, and affirmed that the disease was *parasitic* in origin. In most of the examinations recorded the same results are recorded. He was equally confident that the disease was infectious, of which the records afforded irrefutable evidence.

Petersen referred to the recurrence of carcinoma, and thought it could be clinically divided into recurrence with no connection to the primary tumours and those directly connected therewith. The latter again might be due to a fragment of the original growth being left behind; the former by indirect extension of the morbid virus to neighbouring tissues disposed to take on the disease. The question whether every cancer cell left behind was capable of recurring, or causing a recurrence of the disease, might be answered in the negative, as many of them seemed to perish. In skin affections the giant cells stood as warders and destroyed the cancer cells, nature herself thus bringing about partial recovery unaided. In these cases tuberculosis is often counterfeited, but no tubercle or degenerative caseous matter can be found. Again, the entrance of the cancer cell into the blood can also be prevented and its destructive action annihilated. Notwithstanding these facts, we are not justified in leaving behind any cancer cells that can be removed when operating.

Mikulicz said he had operated on 106 cases for carcinoma of the bowel, which might be more correctly described as 100 genuine carcinomata, five sarcomata, and one epithelioma. The male sex suffered most from this disease. His cases agreed with others in being 80 per cent. males and 40 females, occurring at all periods in life, the favourite site being the cæcum. The disease comes on very insidiously, without any apparent disturbance in the canal, which may remain free from any recurrence for many years after, till stenosis or ileus occurs. He preferred the double operation; first, the removal of the diseased fragment of bowel attaching the ends to the external surface; at a later operation the ends of the bowel are brought together and the wound is closed. By this means peritonitis is avoided and the mortality reduced. His own experience was that the single operation had a mortality of 38·4 per cent., while that of the double operation was only 12·5 per cent. He regretted to have to state that the longest period of perfect freedom from the disease was four years.

Hochenegg said that he had now operated on 282 cases of carcinoma of the bowel, and of three of cancer of the sigmoid flexure; one lived six years perfectly immune from cancer, while the other two never suffered from any carcinomatous changes whatever. He was very much in favour of the sacral method, as he had obtained better results, particularly in the rectal cases, of which he had now performed 174. He lost one case from collapse and heart failure, and one from hæmorrhage eight days after the apiration. He could not endorse the dictum that cancer necessarily returned within three years, since out of 174 cases thirty had remained perfectly healthy and strong, who were operated on many years ago.

Krönlein asked if carcinoma of the stomach was cured by apiration or only palliated, or did the operation prolong life or only make it tolerable. His experience of 264 cases, 195 of which were operated on and sixty nine left untouched, was that, starting from the commencement of the disease, the average duration of life was three months after gastro-enterostomy and fourteen months for gastrectomy. Still individual cases are more successful, as there are still nine alive of the gastro-enterostomy cases and thirteen of the gastrectomy; of the latter it is now eight years since the operation in one case, and in another four years, three years, then two years, and six in their first year after operation of gastrectomy alone. He had no doubt that the latter operation prolonged life, at the same time making it more comfortable.

SEA SICKNESS.

Fischl read a paper on "Mal de Mer" embodying two years' observations in Lloyds as ship doctor. After reviewing the various reputed specifics for the ailment, he stated that nothing had so good an effect as diet in respect of the headache and sickness. Food should be given in small quantities. Kramer found that the choroid and retinal vessels were greatly contracted, leaving the fundus pale during the attack, a fact which indicated the necessity for lowering the head to increase the blood supply. He states that he faithfully devoted himself to this scientific treatment with considerable success. In sixty-nine of the cases two hours with the head low relieved the headache and vomiting. He added that very great injury was done to tuberculous subjects by permitting them to go to sea.

In the discussion Weleminsky said that he took exception to the observation in respect of tuberculous subjects, as English authorities had long been in the habit of sending their consumptive patients to sea with reputed good results; indeed, they were still in the habit of advising their patients to take a sailing vessel in preference to steam, so that the sea exposure might be greater. In addition to this they are in favour of anchoring sanatoria in bays and rivers for this purpose.

Continental Topics.

[FROM OUR SPECIAL CORRESPONDENT.]

"MAL DE MONTAGNE." OR MOUNTAIN-SICKNESS.

EVERY year the mountaineering spirit develops itself more and more among our Continental neighbours, not merely in an increasing number of holiday visitors to the Alps and other high ranges, but in genuine athletic ascensions of difficult and dangerous peaks. The rapid extension of mountain railways and of funiculars, and their steadily increasing crowds of tourist-passengers, testify to this growing love of high lands and glaciers. Naturally, therefore, at this season there is much talk at *table d'hôte* in hotels of "mountain-sickness," and opinions are given freely as to the causes and the effects of *mal de montagne*. Usually the malady and its concomitant vertigo, nausea, heart-fatigue, lassitude and exhaustion are ascribed to two distinct causes, each of which is more or less strongly maintained by its respective advocates. One opinion is that mountain-sickness is caused by the diminution of oxygen in the rarefied atmosphere, or by the diminution of oxygen in the blood, in consequence of the muscular exertion in ascending heights. The other opinion is that partial asphyxia is produced by carbonic acid which freely dissociates, under the reduced atmospheric pressure, from the internal combinations of the organism.

Dr. Mosso, of the Turin University, has been led by a series of experiments to the conclusion that mountain-sickness is chiefly due to the diminution of carbonic acid in the blood to a degree which he calls *acapnos* (without carbonic acid). Carbonic acid escapes from our tissues as soon as atmospheric pressure begins to diminish. Hufner has shown that the dissociation of oxygen from the blood-globules is not produced under altitudes of from 3,000 to 4,500 metres. There is consequently a loss of carbonic acid as the air-pressure lessens, and after attaining an altitude of 3,000 metres there is also a concurrent loss of oxygen.

To determine the effects to be attributed to these gases in producing the malady, Dr. Mosso has breathed various proportions of oxygen and carbonic acid under increasing barometric depressions; and he has made similar experiments upon his assistants and associates. By these experiments in rarefaction he has brought on mountain-sickness in his laboratory under pressures of 246 mm. and 236 mm.; corresponding to altitudes of 6,500 metres and of 8,800 metres. At these pressures it was impossible to overcome the sickness with inspirations of oxygen alone; somnolence and nausea supervened. But by breathing simultaneously the carbonic acid, the somnolence and nausea did not appear. At 6,500 metres the operator felt no uneasiness when with the oxygen respired was mixed a certain proportion of carbonic acid. At 8,800 metres the addition of oxygen alone was of no effect; the operator was absolutely ill and on the point of losing consciousness. The assistants hastened to introduce carbonic acid in the mixture which he respired, and immediately the sensations of vertigo disappeared and the head pains ceased.

An Alpine incident seems to support the theory of the learned Italian physiologist. Two parties of tourists, together forty-five persons, were surprised by a storm on Monte-Rosa, and took refuge in a cabin which had been one of the laboratories of Dr. Mosso, the Cabanna Regina Margharita, at 4,000 metres altitude. This hut, hermetically closed by sheets of copper, was only a cube of fifty-eight metres. The air could only be renewed by two small windows, partially opened, and by the draught of two stove pipes. The atmosphere of the cabin was consequently overcharged with carbonic acid, yet none of the party suffered uneasiness. On the plain, in similar conditions, grave incidents must have occurred. The inference apparently is, that the rapid loss of carbonic acid disarranging the physiological equilibrium may be the principal, and probably the sole, cause of *mal de montagne.*

"CURE DE MONTAGNE."

Just now more attention is being given than in recent years to the benefits derived from prolonged sojourn in mountain resorts, either of moderate elevation, *e.g.*, from 1,250 to 3,000 ft., or Alpine climates (altitudes 3,000 to 7,000 ft. or more). These climates are claimed to have an eminently tonic and reconstructive action on the human organism, giving activity to all its functions, an action becoming more energetic as the altitude increases. According to Dr. Möller, the principal physiological effects of a sojourn in high altitudes are the production of a kind of gymnastic *respiration* and *circulation,* and the augmentation of the excretion of carbonic acid and moisture by the organism, simultaneously with a stimulating action on the skin and the nervous system, the superiority of these effects, as a therapeutic means, being their *continuity* (without any interruption, and without even being noticed) night and day, whether indoors or out of doors, whether with corporeal exercise or in repose, "the body being, so to say, immersed in a continuous air bath, always of the same tension and pressure."

Characteristic results of a mountain climate are the vigour it communicates to the locomotory system, and the rapid recuperation of the muscular powers. As Saussure remarked, "The simple cessation of movement (even without sitting down and within the short space of three or four minutes) seems to so completely restore the strength that we resume our ascent with an assurance of readily reaching the summit."

The Alpine atmosphere especially appears to most favourably affect the nervous system; the calm and restorative sleep here enjoyed correcting the nervous restlessness, thus sensibly reducing, if not curing, the neurasthenia which is so prevalent and so prominent a feature in modern pathology.

In *La Medecine Moderne* (March, 1893), Dr. de la Harpe, of Lausanne, states that high altitudes act beneficially:

1. By the lower temperature rendering the summer heat more tolerable.
2. By the energy of the sunlight, the solar rays having (in addition to their calorific action) a chemical action as marked on the animal as on the vegetable organism.
3. By the *dryness* of the air.
4. By the *purity* of the air, almost absolutely free of dust and microbes.
5. By the diminution of atmospheric pressure, which increases the number of blood-corpuscles, thus promoting circulation and nutrition.

To fairly test a *cure de montagne* it should be taken seriously and methodically; not, as nowadays so usual, rushing rapidly from one altitude and atmosphere to others. To be efficacious a mountain-cure requires a continuous residence of two or three months at about the same elevation; not going higher to-day and descending to lower atmospheric conditions to-morrow. Select an altitude and surroundings considered by competent medical authorities most suitable for the individual case, and remain under approximately the same atmospheric conditions for the prescribed period of "cure."

Formerly the inns and hotels in the highlands were far from being inviting for a long stay, their *cuisines* and sanitary arrangements being anything but beneficial for the delicate or the invalid. Now this is all changed; English home comforts and agreeable environments can be easily found at almost any altitude.

In Tyrol, as an *alpestre* sojourn, Innsbruck is much recommended, having an altitude of over 1,900 feet, very equable climate, Italian skies, sheltered position, university, theatre, large library, fine churches, English services, military music, and the advantages of a city residence, with an hotel, "The Tirolerhof," long and deservedly popular for its English comforts.

In the Berner-Oberland are various stations, *alpestre* and Alpine, and very good hotels for a prolonged visit—at Interlaken the Rugen Hotel, about 1,900 ft. altitude, and conveniently adjacent to the Kleine-Rugen Forest promenades; at Murren the Grand Hôtel des Alpes, 5,400 ft. altitude, face to face with the beautiful peaks and glaciers of the Jungfrau range.

The neighbourhood of the Lucerne lakes offers abundant choice of both *alpestre* and Alpine stations. The town of Lucerne itself, of 1,440 ft. altitude and most readily accessible from England, is a veritable "city of hotels." Pre-eminent among them the well-known palatial "Schweizerhof," and under the same genial proprietorship the adjoining family house, "The Luzernerhof." Lucerne has also the advantages of good shops, churches, museum, library, casino, theatre, races, tennis tournaments, and many other spring, summer, and autumnal amusements, to which will soon be added golf links.

At the same altitude, at Vitznau, on the Lake, is the handsome new "Vitznauerhof," picturesquely located, with gardens, wooded walks, and lake baths.

At 2,100 ft. altitude is the well-known and favourite Grand Hôtel Axenfels; and at 2,360 ft. altitude the Grand Hôtel Axenstein, elegantly rebuilt on the spot our late Queen described as most lovely.

Nearer Lucerne, and now accessible from the town by frequent trams and funicular, is the Grand Hôtel Sonnenberg, 2,350 ft. altitude, with extensive grounds and fine forests, and from its roof one of the best views of Swiss scenery.

On the celebrated Rigi, but pleasantly away from the rush and crowd of summer-trippers, is the home-like and comfortable "Hôtel Rigi-First," 4,800 ft. altitude.

For an Alpine cure Zermatt offers many facilities, as the same *hotelier* family, the Seilers, have various hotels at different altitudes; each of them excellent, although of different characteristics, so as to meet the desires and requirements of every description of guest. In Zermatt village, 5,300 ft. altitude, they have three capital houses, "The Mont Cervin," "The Mont Rose," and "The Zermatterhof." Higher than Zermatt village, they have the "Grand Hôtel Riffelalp," 7,000 ft. altitude, and unsurpassed in Europe as an Alpine residence; and also two smaller hotels, highly esteemed by artists and naturalists, on the Riffelberg and at Lac Noir, each about 8,500 ft. altitude.

To those who winter in the Riviera, and who may prefer to avoid the tedium of travelling to and fro, the Maritime Alps can now afford a very desirable mountain summer and autumn home at Thorenc, four hours' drive from Grasse, amidst pine forests at an altitude of 3,600 ft. Here is the "Grand Hôtel Climatérique," under the able management of Mr. Rost, the popular proprietor of the Grand Hôtel at Grasse.

Grasse itself, being 1,100 ft. altitude, also offers an intermediate resting-place, with an air remarkably pure and tonic, between the Mediterranean level of Cannes and Nice and the higher atmosphere of Thorenc, or of the Savoy and the Swiss Alps.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

OPERATION FOR TWISTED COLON.—Mr. PEYTON BEALE operated on a man, æt. about 30, whom he saw at the hospital, and whose history was narrated to him as follows:—The man about ten days previously had been for a long bicycle ride on an empty stomach; on his return he had hurriedly eaten a meal and immediately complained of pain in the epigastrium; this was soon followed by considerable distension, chiefly at the upper part of the abdomen—this was supposed to be stomach, and stomach tubes were passed, the organ being washed out; a considerable amount of flatus escaped during this proceeding, but the distension was very slightly diminished. The patient had been admitted to the hospital two days before, being seen by Mr. Beale, and by that time his bowels had not acted for eight days. There had been no elevation of temperature, but the pulse had latterly become small and running, the countenance pinched, but no vomiting had occurred. The case appeared to be one of volvulus of the large intestine. The following operation was performed:—An incision about six inches long was made in the middle line, having the umbilicus as its centre; the transverse colon was seen to be enormously distended, being eight inches in diameter. On passing the hand into the abdomen and following the ascending colon downwards a constricting band was felt, and at first was thought to be encircling the gut and so obstructing its lumen, but on further investigation this band appeared to be arranged spirally, so that the finger slipped down by its side much as a person passes down a spiral staircase having a central support. It was thus evident that the colon was twisted, and on further examination it was found that the whole of the ascending, transverse and descending colon was twisted twice round the cæcum, and the sigmoid acting as the fixed part. The twist was unravelled by bringing the whole colon out of the abdominal wound, and then, an assistant's finger being placed in the patient's rectum flatus and fæces were found to escape freely, thus proving that the obstruction had been entirely removed. The colon was returned, and the abdominal wound sutured. Mr. Beale remarked that although a volvulus or twist of some part of the colon is often met with, he had never seen one in which the whole loop of colon had been twisted as in this case, and he assumed that the twist must have been of old standing, leading to partial obstruction which had become complete either after sudden and violent exercise, or as the result of a heavy and hasty meal being taken immediately after that exercise. The only difficulty experienced in the operation, he said, was in getting the enormously distended colon out through the wound without injuring the omentum between it and the stomach, this being, of course, twisted also. The actual seat of obstruction, he pointed out, could not be seen, and so the first impression on feeling it was that produced by the presence of an internal hernia. The difficulty in all these cases of complete obstruction lasting for more than a few days, he thought, was that it led to paralysis of the intestine, this paralysis frequently causing death. He had found that in such cases the administration of a large dose of calomel as soon as the patient had recovered from the anæsthetic was in some cases beneficial, though it was decidedly risky, but a small dose seemed to be quite ineffectual in this condition. He had tried massage and electricity in cases of paralysed intestine after the strangulation had been relieved, but had not found either to be of any use. The stomach symptoms, he said, were probably due to tension upon its greater curvature owing to the twisted omentum, otherwise the case was a fairly typical one of complete obstruction not due to the presence of a new growth or of an inflammatory process.

Boracic Acid in Milk.

A MILK dealer at Manchester was fined last week for selling milk which contained four grains of boracic acid to the pint on the ground that the milk was no longer of the nature and quality demanded.

A Pathological Scholarship.

MR. J. FRANCIS MASON, of Freeland Lodge, Woodstock, Oxfordshire, has, through Dr. Caverhill, of Edinburgh, offered a scholarship of £200 a year, with extension to two or three years if the work seems to promise good results, for the purpose of carrying on investigation into the physiology and pathology of the thymus gland, including, if necessary, collateral investigations on the other ductless glands. The founder of the scholarship has asked Dr. Caverhill and Professor Woodhead to assist him to select a suitable candidate. Preference will be given to those who have already made a study of the thymus or other ductless glands, or have given some evidence of their fitness to carry on this or similar work, and who will devote the whole of their time during their tenure of the scholarship to the special research mentioned. Every facility for carrying on this work in the Pathological Laboratories, Cambridge, will be placed at the disposal of the scholar.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 27, 1902.

CIVILISATION AND THE BIRTH-RATE.

We have been invited to gauge the civilisation of different countries by the quantity of soap they use, the miles of paper consumed in newspaper production, and in various ways which are simple if not absolutely trustworthy. We may add another factor to the arithmetical calculation, viz., the birth-rate, which slowly but surely diminishes in proportion to the advance of the community along the path of civilisation. We find, for instance, that during the twenty years ending 1895 the birth-rate in Germany fell from 42 to 36, and in England from 36 to 29. In France, a country in which what may be termed the civilised birth-rate was long since reached, the fall is less perceptible, amounting only to ·8 per cent. (26 to 25·2). The increased cost of living does not account for the decrease, since, although the cost has tangibly increased, a far greater change has taken place in respect of the standard of comfort. Young people are no longer content to wed under conditions which satisfied their predecessors, and they are gradually acquiring a degree of self-control—in regard to marriage—which enables them to await more auspicious circumstances. Then, too, the general intelligence undergoes development, and possible bridegrooms, no doubt, take into consideration the question of providing for their offspring, and it cannot be denied that the cost of educating children up to the present standard, low as it is, imposes on the parents burdens previously unknown. Moreover, the period of education and technical training is longer in proportion to the heightening of the standard. The wealth of a nation, especially when fairly equally distributed, as is the case in France, and as it is notoriously not the case in this country, tends to restrict fertility; in other words, the richer the individual becomes the more foresight does he develop and the less will he leave to chance. In countries where the working classes are, intellectually speaking, still undeveloped, the marriage and birth-rates are determined, to a great extent, by fluctuations in the price of bread, the rate of interest, and a thousand other economical conditions which exert a direct influence on the cost of living. In nations of higher intellectual development such material circumstances are of vastly less import, restricted fertility being due to influences of psychical origin. Another circumstance which cannot but have a powerful effect on the inclination to marry is the gradual emancipation of woman. Hitherto marriage has in great measure been the only "occupation" for which women were trained and for which they were in any sense fit. Thanks to the more general employment of women in various capacities they have been enabled to conquer an independence which many of them, we may be sure, will prefer to the joys of maternity and the responsibilities which they entail. Moreover, the very fact that women now enter openly into competition with men in walks of life previously restricted to the latter tends to reduce the number of possible husbands by reducing the sum total of salaries earned by them. In spite, however, of all the specious explanations which are forthcoming to account for this universal tendency to postpone the date of marriage and thus reduce the period of child-bearing, one is driven to the conclusion that physical conditions are of comparatively little moment in determining the movement. The interests of the nation are here at variance with those of the individual, and, as it is the individual who decides the matter, he is likely to decide it in accordance with his own views as to what is best for him. The injunction to increase and multiply no longer applies to older nations where the labour market is overcrowded and where a large proportion of the population live on the verge of starvation in an abyss of ignorance and dirt. A smaller birth-rate may introduce new and altered conditions into our social system, not necessarily of a kind detrimental to a high standard of general well-being, and when the surplus population is reduced to a great extent the nation will be less disposed to sacrifice lives in destructive wars. The conclusion to be drawn is that there is no physiological basis to the diminished birth-rate, since it is dependent on causes well within our control, individually, though not collectively.

THE ÆTIOLOGY OF TYPHOID FEVER.

The ætiology of typhoid fever will for long remain one of the most interesting of medical problems. Since Eberth, in 1880, discovered the bacillus that is known by his name, little progress has been made on the subject. That the bacillus is the toxic agent has, we believe, been demonstrated; but it yet remains for us to learn the conditions under which the bacillus developes its toxin. Some progress has, however, been made; we have come to the knowledge that the Eberth bacillus, when passed in the liquid fæces of a patient, is innocuous, and remains so for some time. It has also been ascertained that its vitality is great, and that typhoid fæcal discharges are not rendered aseptic by being buried in the soil. Indeed, recent investigations go to show that such a method of disposing of typhoid dejecta is about the most dangerous that could be adopted. When the bacilli-charged stool is poured into the earth, the bacillus quickly acquires its uncharacteristic properties and soon makes its way to the surface of the soil, where the fæcal impregnated soil has furnished the *Musca domestica* a suitable resting place. At this point medicine awaits the aid of the bacteriologist to learn the life history of the Eberth bacillus. From clinical observations it seems probable that in the earlier metamorphoses of the bacillus, in what we may call for convenience sake the spore stage, the miniature bacillus may be inhaled and make its way through the pulmonary tissues. That typhoid is usually water-borne may hold good for large cities, but it altogether fails to explain the prevalence of the disease in hot, dry countries, or in camps of modern armies where the water is sterilised by boiling. The statement that in camps soldiers prefer to drink contaminated water and take the risk of typhoid rather than use the sterilised water is to charge them with an absence of common sense. We view the outbreaks of the fever difficulty. We consider that in hot climates the dust storms and dust laden air not unfrequently carry bacilli spores, which will account for a certain percentage of cases, not a large percentage. In camps the common house fly is the principal agent in disseminating the poison. The latrines of the soldiers and the stools of the hospital patients are the feeding places of the flies, and the dejecta of one patient affords sufficient material to infect a thousand. The warmth of the tents and hospitals attracts the flies, and the milk, meat, and indeed all the food on the premises, become infected. This source of infection is the great danger of typhoid fever in a farmhouse from which milk is supplied, either direct to families or to creameries. The active part that the house fly plays in producing epidemics of typhoid it was impossible to judge of until Dr. Packard, of Boston, 1874, made known its life history. We are too much given to formulate our opinions on disease from facts ascertained in this country without taking into account the course the disease runs elsewhere. How different the conditions under which typhoid occurs in Australia, and how dissimilar the symptoms. We have no explanation of the immunity of the native of India to the disease. He drinks notoriously unclean water, he suffers from such filth diseases as cholera and plague, and from a form of relapsing fever, with purging, and although the European resident gets typhoid, he goes free. Neither in this country nor in France has the disease during the last two decades of the nineteenth century been so typical of the classic descriptions of Louis and Jenner than it was. It is, however, satisfactory to recognise that we can by sterilising typhoid stools immediately they are passed do much to stamp out the disease. To secure this very desirable object the antiseptic should not be a volatile one, for all antiseptics of that nature, such as carbolic acid, and admixtures of the creoline series, are practically useless; the antiseptic volatilise and the period of suspended animation of the bacillus passes off, and he acquires his virulence and activity in undiminished amount. A trustworthy antiseptic in such cases is a solution of pure sulphate of copper, which should be poured into the night chair immediately before the patient defæcates. The copper salt not alone sterilises the stool, but is a poison to flies. We have also learned the necessity of keeping all food under gauze or other covers, so that it may not become infected. But until we know the life history of the bacillus our prophylactic measures will be incomplete.

MODERN ASPECTS OF DENTAL SCIENCE.

THE progressive nature of medical science is well exemplified in its off-shoot of dental practice. Some of the wider aspects of that most necessary branch of study have sprung directly from the comparatively recent discoveries of bacteriology. Perhaps the most striking application of the new knowledge has been made by Dr. Hunter, who has shown that various forms of anæmia are due to septic conditions of the oral cavity. The recognition of the important fact that chronic mild septicæmia and ill-health may arise from carious teeth opens up at once a wide field both of prevention and of rational therapeutics. That theory marks an immense advance upon the old-fashioned attitude which limited the damage to health arising from bad teeth simply to lessened powers of mastication. The whole subject was recently dealt with in an interesting manner by the President of the Western Branch of the British Dental Association, Mr. Greatrex Yates. He contended that the question was one of the widest national importance. The ravages of dental caries, he said in so many words, threaten to become a national problem which must sooner or later be dealt with by the State, if we are to maintain our position as the foremost nation. The disease and the loss of teeth mean the loss of energy, ambition, and many of the attributes for which our race is held famous. The importance of this general principle has been officially recognised in the standard of soundness of teeth now enforced in the case of recruits for the Services. In the recent South African war, we are inclined to think the test was pushed to an extreme. The presence of one or two carious teeth in a man of otherwise good physical qualities can surely have little effect upon his health during a short service campaign. The effect of bad teeth upon the general constitution is likely to be an extremely slow process, especially in persons who at the outset are robust. At the same time we are fully in accord with Mr. Yates's general proposition, and we heartily support his contention that all State schools, asylums, and Services should be under systematic dental supervision. It has been asserted on good authority that a systematic examination of the teeth of school children at home and abroad — in the countries of Europe, Canada and the United States — has revealed the fact that from 90 to 95 per cent. have defective teeth. There is a good deal to be said in favour of the contention that prisoners should be entitled to claim skilled dental service. On one point we emphatically agree with Mr. Yates, namely, the need of greatly extended facilities in the case of the poor. A glance into the mouth of the average dispensary patient reveals a septic condition that probably accounts for a considerable proportion of the ailments for which relief is sought. To attempt to cure dyspepsia without first securing a healthy mouth is to treat a symptom while ignoring its most probable cause. The thanks of the medical profession are due to the excellent pioneer work that has been so long and faithfully performed by the more scientific members of the dental profession.

Notes on Current Topics.

Anti-Tuberculous (Bovine) Immunisation.

Von Behring's report, which concentrates the essence of the results obtained during seven years systematic investigation of bovine tuberculosis, conducted by himself and his associates at Marburg, is now the property of the curious and expectant public. It contains proof of a decidedly affirmative reply to the question which he himself proposed: "Is it now proven that individuals of the bovine family can be voluntarily immunised against tuberculosis, so as to be able to withstand infection with a virus which is fatal to control animals?" Accordingly, we have here, as one of our trans-Atlantic contemporaries puts it, "a brilliant discovery in animal therapeutics reflected across an immeasurable field in human therapeutics." Von Behring directs attention to the want of any very striking morphological and cultural variation; to the identity of the anatomical and bacteriological findings after experimental inoculation of guinea-pigs and puppies; to the successful inoculation of cattle with tubercle bacilli derived from human hosts; to the possibility of immunising cattle against bovine tuberculosis by means of the virus of human tuberculosis. "Furthermore, the results of chemical analysis favour the notion of chemical unity and strengthen the foundations of the theory of bacteriological unity." These are facts and arguments which strongly appeal to the critical and argumentative powers of Professor Koch, who still appears to hold so strongly to his hypothesis of the duality of human and bovine tuberculosis. Reverting to the subject of preventive (bovine) inoculation against tuberculosis, it is both instructive and interesting to note that the method of inoculation practised by von Behring is similar in principle to that of vaccination, rather than to the preventive inoculation employed in diphtheria or tetanus. And the immunisation so obtained is ascribed to an alteration in the biological condition of the animal, due to the infection to which it is artificially subjected; and is not attributable to the presence in the organism of a substance separable from the veins. "It is an isopathic self-immunisation, in contradistinction to an immunisation by anti-bodies possessing antitoxic or anti-bacterial properties." Von Behring has satisfied himself, and his procedures seem perfectly satisfying to an unprejudiced critic, that he has produced a virus by means of which unprotected cattle can be caused to die of acute miliary tuberculosis in a reasonably brief period; and that he has prepared a weakened virus which has a saving power against the deadlier microbic poison. We feel sure that all our readers must look forward, as we do, with curious and anxious expectation for the final adjustment of the contending hypotheses now held by such eminent and earnest scientific inquirers as Koch and von Behring. In the interests of suffering humanity, the sooner the truth is finally established regarding this truly tremendous problem the better. We must also remark, in closing, that even if Koch's hypothesis came to be finally established, the results of von Behring's investigations, which have given a result so colossal as the power of preventing tuberculosis in cattle, will still retain a vast and perennial value for the human race throughout the whole civilised world.

Death of Dr. Schenk.

The death is announced of Dr. Leopold Schenk, formerly Professor of Embryology and Physiology at the University of Vienna. Dr. Schenk achieved notoriety, if not fame, by his work on the possibility of determining the sex of the fœtus by regulating the diet of the mother, an hypothesis which bore no evidence on the face of it of being based on careful scientific observation. It obtained forthwith a world-wide *succès de curiosité*, but the manner in which the alleged discovery was made public aroused the resentment of his University colleagues to such a pitch that Dr. Schenk was compelled to resign his chair, *noblesse oblige*, and a man of science who has attained to the dignity of a professorship owes it to his colleagues and to the institution to which he belongs to abstain from pandering to the gallery by promulgating ill-digested and scientifically unconfirmed theories.

The Treatment of Hæmorrhoids.

To the many operative measures for the treatment of piles, Potarca, the Roumanian, has added another. It might, however, be more accurate to say that he has adopted the principle of Whitehead's operation and modified the procedure in a most ingenious manner. Having anæsthetised the patient, he inserts a wooden cylinder, three or four inches long and from an inch to an inch and a-half in diameter, into the rectum. To allow of the cylinder being the more easily retained it is made a little thicker in the middle than at the ends, and it is provided with a copper handle. The second stage of the operation is now commenced by passing a circle of pins through the muco-cutaneous surface at the anal orifice and pressing them into the wooden cylinder. Then, by partially withdrawing the cylinder, the anal aperture is made to bulge, after which a circular incision is carried around it, just outside the pins. A dissection of the external sphincter, exposing the rectal mucous membrane and dilated veins, is then made and the veins are ligated or excised. The cylinder is now pushed back, and the wound sutured. In old-standing severe cases the incision is carried down to the cylinder, and all the mucous membrane between the pins and the cutaneous surface removed, the healthy mucous tissue being drawn down and sutured to the cutaneous tissue. The operation is easy of performance, and is well suited for cases of hæmorrhoids, complicated ulcers, and fissures.

Ethyl Chloride as an Anæsthetic.

The most recent claimant for favour as an agreeable and safe anæsthetic is ethyl chloride. It is a colourless mobile liquid having a peculiar and pleasant odour and a sweetish burning taste. The compound was first discovered by Basil Valentine, by mixing the spirit of common salt with spirits of wine and distilling thrice. In 1848 Glauber rediscovered the salt, "a fine, clear *oleum vini*" swimming on the top, "which is not the least potent of cordials." From its chemical formula, $C_2 H_5 Cl$, it should be equally safe as ether, even though one death in a series of 2,500 anæsthetisations took place at Innsbrück, under Dr. Lothersser's care. By using a closed mask anæsthesia is quickly produced, and there is no unpleasant after-effects. It has, however, many drawbacks; the anæsthesia is never complete, struggling usually occurs, and the muscles are not relaxed as in chloroformisation. Patients no doubt pass quickly under the influence of the drug, but they recover quite as quickly from its effects. Uncertain in action, evanescent in its effects, and without power to relax the muscle tissue, we cannot see that the chloride is a valuable addition to the list of agents for producing transient anæsthesia.

Heredity in Crime.

The record case to use in illustration of heredity in crime has long been the complex one supplied by the history of the famous "Jukes" family—which was made the subject of a monograph by R. L. Dugdale:—"The Jukes: A Study in Crime, Pauperism, Disease, and Heredity," which was published in 1877 by Putnam's, New York. The ancestor of this family of gloomy celebrity was born in an approximately inaccessible locality in the State of New York, in the third or fourth decade of the eighteenth century. He was a descendant of early Dutch settlers; and lived the life of a backwoodsman—hunting, fishing, loafing, drinking, &c., by fits and starts. This is the mode of life to which the instinctive criminal naturally gravitates. He left a numerous issue, of which a large proportion was illegitimate. Two of the sons married the "Jukes" sisters—probably illegitimate. There were five of the "Jukes" sisters; and, of their numerous descendants, 709 have been traced—occupying a period of five generations. Of this large number there was a certain proportion of honest workers; but it has been "on the whole a family of criminals and prostitutes, of vagabonds and paupers." There were 76 convicted criminals, and, of the females, 52·40 were prostitutes; the normal average has been estimated at 1·66 per cent.; 180 had received out-door relief during an (approximate) aggregate period of 2,300 years. Dugdale estimates the total cost to the State, during 75 years, at a million and a quarter dollars. Of the men, not 20 were skilled workmen; and 10 of these had learned their trades in prison. Mrs. M. J. Annable, State Superintendent of the Rescue Work of the Women's Christian Temperance Union, New York, has discussed the same subject in the *Boston Medical and Surgical Journal*, and gives the essence of the family history of a woman—the keeper of a house of ill-fame—who died in 1827, at the age of 51. Her descendants have been numbered at 800, of whom 700 have been convicted at least once. There were 342 drunkards, 127 women of immoral character, and 37 murderers—all of whom have been executed. So that the descendants of that one woman have cost the State 3,000,000 dollars—for trials, imprisonments, and executions!

Malta Fever.

It is, of course, well known to travelled medical men that Malta fever is not confined to the island of Malta; it is of common occurrence on the shores of the Mediterranean, though it is endemic in the island of Malta. Indeed, Manson states that "it is highly probable that the same or a similar fever occurs in many parts of the tropical world, having been confounded hitherto with malarial fever." And Major Semple, Director of the Pasteur Institute, Kasauli, affirms that "it is not uncommon in the Punjab, and especially up about the frontier, while there have been several cases in Simla lately, and some in Delhi, Agra, and Allahabad." It is also known by sundry synonyms: "Mediterranean Fever," "Rock Fever of Gibraltar," "Neapolitan Fever," and "Undulating Fever." In 1887 Surgeon-Major Bruce announced the discovery of the specific organism of the disease, which he had obtained from the spleen by cultivation, and which "he established as the causal agency by inoculating monkeys with the culture." The infected monkeys died—from the thirteenth to the twentieth day. Accidental inoculation of the human subject with a culture has also resulted in the production of Malta fever. The period of incubation appears to vary from about six to fourteen days, and the mortality is about 2 per cent. The varying symptoms in different cases have suggested the division into three types: *malignant*, where the onset is sudden, with intense nervous prostration, and a temperature of 104°-105° for some days; *undulatory*, said by Hughes to be the commonest, when there develops a temperature resembling that of typhoid, with a tendency to numerous relapses—each relapse lasting about ten days; *intermittent*, in which the temperature rises every day about 11 a.m., and gradually falls after midnight to normal, or nearly so. The frequency of occurrence is greatest in the driest months of the year, reaching the maximum in July.

A Drawback of Lady Doctors.

One drawback incidental to the practise of medicine by women is the unconscionable time they require to respond to a night call. A man jumps into his dressing grown and trips lightly down the stairs, twisting his moustache into shape as he goes. The woman doctor, on the other hand, has to go through numerous solemn rites before she dare show herself in public, and it may well happen that the time consumed in this, femininely-regarded, indispensable preparation appears to the sufferer and his friends to be unduly long. Only last week, at an inquest held in South London on the body of an unfortunate girl who had sustained fatal injuries as the result of her cycle skidding and throwing her under an omnibus, the indignant father complained that she had been left twenty-five minutes without attention at the infirmary, a delay which was ascribed to the fact that the medical resident at the infirmary was a woman, who, "of course," took somewhat longer to dress than would a man. In the opinion of the jury, this is a sufficient reason for always keeping a medical man on the premises, but it appears that the guardians do not offer sufficient remuneration to induce a medical man to reside in the infirmary. If women are to hold their own in medicine they will have to discover a means of obviating this and sundry other drawbacks incidental to their sex.

Leucocytes and Diagnosis.

The importance of a microscopic examination of the blood in the estimation of both red corpuscles and white is coming to be more and more recognised, not only in diseases of the blood, but in those of a general nature. In many undefined cases it is found that the point of diagnosis is immediately cleared by a blood examination. Thus, in typhoid fever, lymphocytosis is the rule, while leucocytosis is stated never to occur unless there is some complication. As the latter is the rule in most infectious diseases and inflammatory conditions, the value of the distinction is obvious, more especially as the lymphocytosis in typhoid occurs early, along with a leucopenia, some time before the Widal reaction is established. An examination of the blood is stated to distinguish at once a case of early typhoid from one of pneumonia or influenza. Again, a marked leucocytosis occurs in such conditions as appendicitis, pyosalpinx, and suppurating ovarian cysts, thereby distinguishing them not only from typhoid but from malaria, in which leucopenia is the rule. And not only in the early stages of disease is the condition of the leucocytes of assistance, but during its progress any marked increase or diminution in their number points to some change of importance in the patient's system. Thus, a sudden leucocytosis in typhoid very frequently points to a perforation. The whole subject is very well summarised in a recent paper by Dr. Brown, of Baltimore (*Medical News*, July 26th) who quotes two cases in which a sudden increase in the number of leucocytes from about seventeen to thirty-four thousand per cmm. synchronised with a perforation of the appendix.

The Registration of "Unknowns" at Hospitals.

The unfortunate occurrence in connection with a case "unknown," admitted into the Great Northern Hospital, has drawn attention to the importance of the identification of patients. We believe this is generally recognised by all hospitals; and resident medical officers are usually freely alive to the necessity of securing the names and addresses of those who bring cases to hospital, and, where the services of the police have been called in, the number of the Law's representative is, we believe, generally taken. It would be well that all house surgeons and house physicians should be notified of the need for ensuring that this formality is attended to.

The Ætiology of Alpine Accidents.

The annual invasion of the Alps demands heavy toll of human lives. The losses this year are startlingly heavy. Much of the sacrifice is needless. Many deaths occur from preventable causes. The ætiology of alpine accidents calls for serious study. A Swiss medical man has sought to throw light on this matter. The results of his researches have recently been published in the reports of the Swiss Alpine Club in Berne. His studies cover ten years—1890-1901. During this period 305 have lost their lives, of whom 218 were tourists, 73 guides, and 14 porters. As regards nationality, 190 were Germans, including Austrians, 48 Swiss, 23 Italians, 18 English or American, and 15 French. Mountaineering is scarcely taken seriously nowadays. The number of climbers to the summit of Mount Cenis in the course of a year is about 8,000; 1,000 fewer ascend Niesen, and 6,000 reach the peak of Raxalpe, in Austria, while 420 succeed in reaching the top of Wilde Kaiser, and 120 that of Mont Blanc. Sometimes as many as twenty climbers start for the Wetterhorn and Mont Rosa on one day. It is computed that in a year 78,000 visit the German-Austrian Alpine region, while 22,000 tour in Central or West Alps, making a total of 100,000. A large proportion of these climb more or less, but only twenty-seven on an average lose their lives every year. There are many factors in the causation of these accidents—foolhardy adventurousness, vanity, the spirit of emulation, carelessness, want of experience, absent-mindedness, parsimony. It is also shown that many accidents have been caused by the use of alcoholic drinks. In twilight, and during misty weather, and, of course, at the time of storms, dangers are peculiarly liable to be entered into without adequate means of escape. In spite of all hazards the lure of the mountains cannot be overcome, and mountaineering is not likely to diminish in popularity, but it is most desirable that climbers should enter on their pursuit with knowledge and judgment.

The Use of Supra-Renal Extract in Bladder Surgery.

THE vaso-constrictor properties of supra-renal extract are coming to be so well known that every addition to the uses to which they can be put is of importance. Von Fritz, at Vienna, has lately called attention to the value of this extract in cystoscopy, in the case of patients who suffer from vesical hæmorrhage. He states that 100 to 150 c.cs. introduced into the bladder and left there for three or four minutes check all hæmorrhage temporarily, and allow the operator to obtain an uninterrupted view of the mucous membrane. Similarly, the removal of small neoplasms of the bladder is greatly facilitated by a preliminary use of supra-renal extract. Fritsch further states that the passage of a catheter, in cases of tight stricture or of a large prostate, is considerably facilitated by the preliminary injection of the extract into the urethra, a result which he explains as being due to the anæmia of the mucous membrane which is induced. The risk of the recurrence of hæmorrhage in the case of a removed growth after the effect of the extract has passed off must not be forgotten, and means must be taken to prevent it. Fritsch records one case in which such an accident happened.

A Cure for Red Noses.

SOME unfortunate persons suffer from a tendency to redness of the nose, due to fugitive erythema which supervenes under slight causes, either internal or external. A Berlin physician, not improbably a sufferer himself, announces that this ephemeral but distressing condition may be cured by the application of benzine. He applies it on a folded piece of lint, which is kept in contact with the erythematous area for a few seconds, carefully avoiding any friction of the skin. If the application be repeated a few times the skin covering the nose becomes paler and less shiny. The benzine application may even be used as a prophylactic, so that persons whose noses are liable to vie in hue after dinner with the red, red rose can avert the calamity by including benzine among their cosmetic appliances.

The Antiseptic Properties of Perfumes.

THE search for a new antiseptic still continues to occupy the attention of many observers. Paradoxical as it may seem, the latest additions to the list are in reality the oldest of all. The researches of an Italian, M. Calvello, at Palermo, into the antiseptic value of various spices and fragrant plants show that essences derived from these substances, and dissolved in six parts of alcohol, form, when added in different proportions to water, antiseptics which compare favourably with corrosive sublimate solution of the usual strength. Essence of cinnamon is perhaps the most satisfactory, then come essence of thyme and essence of geranium, and, lastly, essence of patchouli. Essence of cinnamon, when used at a strength of 7 or 8 per cent., gave the same results as corrosive sublimate lotion at a strength of 0·1 per cent., while thyme at 11 per cent. and geranium at 17 per cent. were similarly comparable. For absolute sterilisation, it was found necessary to increase the strength of cinnamon to 9 per cent. and of thyme and geranium to 12 and 18 per cent. respectively. Patchouli was far weaker in its antiseptic properties, and even at a strength of 50 per cent. was untrustworthy. In testing the potency of the various essences the hands were immersed in them for five minutes.

A Cemetery Scandal.

THE inadequate nature of the death registration laws has been repeatedly before the public during recent years. It seems incredible that the cemetery authorities will accept bodies for burial without receiving proper official certificates from the undertaker. Such laxity would clearly pave the way to the easy disposal of bodies of persons who have been murdered. It seems, however, from the evidence given at the West Ham Coroner's Court last week, that the Plaistow Cemetery authorities are prepared to inter bodies without any burial order, subject, presumably, to the condition that if the certificate be not forwarded within a week the coroner must be communicated with. Two bodies were removed from the mortuary of St. George's-in-the-East Infirmary under such circumstances, and as they were awaiting inquest, and there was some doubt as to the cause of death, their exhumation was ordered. It was then found that the bodies were removed from the mortuary after an inquest had been ordered by the coroner. The explanation given was that the ordinary gate porter, who looked after the mortuary, was away on his holidays. The excuse appears hardly adequate for such a scandalous breach of duty and decorum. The law that can permit bodies to be buried without certification from a registrar obviously requires radical reform.

Death from Glanders.

LAST week a London carman died of glanders under circumstances that should have an educative value to the public. It seems that he worked for a coal merchant who had six horses, one of which died two months ago from so-called gangrene of the lung. In the light of the carman's death there can be little reasonable doubt that the horse died from glanders, although the owner and other witnesses at the inquest were confident that there had been no such disease in the stables. The London County Council inspector is reported to have said that gangrene of the lungs was getting very near to glanders. In this case we should have thought the two pathological conditions were identical. There is no disease that could be more absolutely detected by modern scientific measures, to wit, the mallein test. The systematic examination of all stables where horses have died from septic diseases would enable the Council to stamp out the disease, and, if required, compulsory powers could be readily obtained for the purpose. It is a national reproach that this loathsome and deadly, but readily preventable, disease should be allowed to linger on in our midst.

Age in Reference to Cancer.

A VERY brief study of cancer returns in respect of the age of the subjects makes it abundantly clear that, whatever may be the proximal cause of the affection, it is essentially a disease of advanced life. An examination of the figures seems to show that, although the total number of deaths from cancer has enormously increased of late, the increase is not due to there being a larger number of cases occurring in what may be termed the precancerous age, but to a greater number of cases, not necessarily a greater fatality, in the ages recognised to be liable to cancerous degeneration. Just as the proportion of infantile deaths from scarlet fever and diphtheria underwent a marked increase when small-pox was inhibited by vaccination, so the proportion of deaths from cancer increases now that a larger number of persons survive and reach an advanced life. It follows that cancer only attacks tissues the vitality whereof has been reduced by chronic irritation or constitutional decay, and this fact must render it all the more difficult to discover an effectual remedy unless the remedy at the same time comprises a means of restoring the vitality of the tissues.

The Toxicity of Boracic Acid and Borax.

IT is too generally assumed that boracic acid and its salt, borax, are free from toxic properties, so much so that milk dealers do not hesitate to introduce comparatively large quantities into their milk as preservatives, in ignorance or indifference to the possible effects on the consumers thereof. Dr. Herviault, of Rennes, in his graduation thesis, calls attention to the cutaneous symptoms which have been observed to follow the employment of boracic acid enemata. Such injections have, in a number of instances, been followed by erythematous eruptions commencing in the form of papules disseminated over a more or less extensive area. The eruption is associated with a rise of temperature, and is followed by well-marked desquamation. He notes that these symptoms subsided directly the enemata were suspended. Similar symptoms have been known to follow the use of boricated gargles, but so far as the enemata eruptions are concerned we are not satisfied that they were really due to the boracic constituent, since erythematous eruptions have often been reported as following the injection of fluid into the large intestine. It seems highly probable that the symptoms are due to the absorption of ptomaines from the intestine, such absorption being determined by the increase of intra-intestinal pressure consequent upon the injections.

Gastric Ulcer and Cancer.

IN regard to the origin of carcinoma of the stomach from the familiar chronic "round ulcer," it is asserted (a) that gastric carcinoma of such origin arises from the parts of the edge most exposed to mechanical irritation by the contents of the stomach, and, accordingly, that in the pyloric region such growth usually springs from the lower margin. This origin of pyloric cancer is said, moreover, to be very frequent, while less so, proportionately, in other parts of the stomach. Accordingly, early gastro-enterostomy is strongly recommended in cases where there is reason to believe that the puckering of an ulcer has commenced to narrow the pyloric orifice; and when the operation is not allowed by the patient, or is not thought advisable, the latter should chiefly use liquid, semi-liquid, and fatty foods. A special caution is given in respect of the ingestion of pieces of crust, of crisply toasted or fried portions of bread; also in the ingestion of carbo-hydrates. This is especially important in case of elderly people with few teeth and insufficient saliva. For such persons the use of taka-diastase is recommended as a digestive adjunct.

Luminous Microbes.

A NEW ray of light has suddenly flashed across the pathway of man's research in the domain of the obscure and unknown. The startling novelty of the fact in the present instance is that it has issued from the physical entity of man's greatest physical enemy—the microbe. We have for so many years been hearing of the deadly and death-dealing qualities and powers of bacteria in general, that we felt quite refreshed when we commenced to learn, comparatively recently, that some of these invisible enemies of ours performed some actually useful functions in our economy. And when we found it definitely stated—even proved—that their presence was *necessary*, not only to our well-being but to our very existence, we found that the full burden of the total ills of life was not, after all, so hard to bear as we had been accustomed to think it. The latest of their newly-ascertained properties turns out to be one of luminosity. Their radio-activity in this department has been found so energetic as to produce photographs, two of which are reproduced to illustrate a communication on this subject by Professor B. A. Gregory to the August number of the *Leisure Hour*. One is of a flask containing some of the luminous bacteria; the other, correspondingly appropriate, is of a portrait of their life-long enemy, Lord Lister. The latter required an exposure of several hours, so that there is no immediate prospect of bacterial luminosity becoming utilisable for the production of ordinary photography of the human face divine. The slowness of the action is due to the very interesting fact that, although the bacteria in question give out a copious supply of rays which affect the retina, their luminosity is peculiarly deficient in the special rays which affect the sensitive plate of the photographer. This is a striking example of the provident economy of nature. The emission of the invisible *actinic* rays would be of no functional advantage to those organisms; and, accordingly, none such are produced. They consume a certain amount of organic nutriment, together with a requisite proportion of oxygen; part of the energy so acquired is given out as light. The corresponding food and air used by human beings produce a certain proportion of heat: this maintains the uniform temperature of the body. Curious it is to note that the light emitted by the fire-fly has been ascertained to be of the same perfect character; there is no energy wasted in the production of invisible rays. Accordingly, we have the remarkable facts that the light produced by bacteria and by the fire-fly, respectively, are by far the most perfect known—so far as their amount goes in each case. In every known form of artificial illumination, the light rays are accompanied by a larger proportion of invisible ones—which necessarily means a great waste of energy. Nature does not squander her resources in that way.

(a) *Journal of American Medical Association*, July, 1902.

The Nostrum Fraud.

NOTHING seems too ridiculous or grotesque for a certain class of the population in the matter of nostrums. No matter how preposterous the statements may be, they are greedily swallowed along with the precious compound. Far from seeking to protect the poor and ignorant against the manœuvres of the unscrupulous host who prey upon their simplicity and credulity, the Government paternally gives them a quasi-official status by consenting to affix a stamp in exchange for a share of the plunder. Every week has its record of little victims who have succumbed, not necessarily to the remedy, since this is usually inert, but to the neglect of ordinary precautions under the empire of the confidence begotten of wholly mendacious assertions. A day or two since the Westminster Coroner directed attention to the "extremely dishonest" description published of a certain nostrum known as "Mother Job's Liquid Fruit," adding, according to the report, that the Government "made money out of dishonest advertising." The immorality of the medical stamp tax will one day, no doubt, be appreciated, but, so far, succeeding Governments have stifled all opposition thereto.

An Epidemic of Ringworm.

THE occurrence of a "small epidemic of *microsporon Audouini*" has been reported by Dr. Gunsett, of Strassburg. This type of ringworm forms between 80 and 90 per cent. of all the cases in this country, and 60 per cent. of the cases reported in Paris; but it is unusual in Germany and Italy, and is very rare in the eastern parts of Europe. Until two years before Dr. Gunsett's report, the *microsporon Audouini* was unknown in Strassburg; and during the intervening past two years there were but four cases reported. The recent small epidemic included seven perfectly typical cases. The scalp alone was affected. The patients were all boys, of whom the ages ranged between seven and nine years.

The Microbe of Beri-Beri.

AN outbreak of beri-beri, with several deaths, is reported to have taken place on a French vessel which arrived last week at Falmouth from Caleta Buena. This disease has been a mystery hitherto, and it is therefore interesting to note that Major Rost, of the Indian Medical Service, attributes it to an organism found in decaying rice and in liquors prepared therefrom. The ingestion of cultures of the organism is said to give rise in fowls to symptoms like beri-beri in man, but we should prefer some more definite information than this fancied resemblance before we accord this organism a scientific status.

Muzzling the Medical Staff.

FOR reasons which are not, to us, apparent, the Committee of Management of the Swansea Hospital have unanimously passed a resolution to the effect that the Annual Report of the medical staff shall not be published in future until and unless it has been submitted to the Board. The decision is likely to give rise to trouble, since the medical staff are the servants of the Governors and not of the Committee, and it is not easy to divine what object the Board has in view unless they desire, on occasion, to inhibit the publication of inconvenient facts.

THE P. and O. steamer *Arcadia*, which sailed last Thursday, takes out several medical men to reinforce the Indian Medical Service in the new scheme for staying the plague. Some thirty-seven practitioners have been selected for the service, and they will proceed to the Punjaub for the purpose of carrying out extensive inoculations.

MR. NORMAN HENRY FORBES, F.R.C.S.Ed., has been appointed a Knight of Grace of the Order of St. John at Jerusalem.

THE DUKE OF BEDFORD has signified to the hon. treasurer of the Cancer Research Fund, under the direction of the Royal College of Physicians of London and the Royal College of Surgeons of England, his intention to contribute £1,000 a year for three years to this fund.

MAJOR W. G. MACPHERSON, C.M.G., Royal Army Medical Corps, a member of the Army Medical Service Advisory Board, and of the Army Sanitary Committee, has been selected for service in South Africa.

Typhoid in Limerick.

A SERIOUS outbreak of typhoid fever is announced in Limerick city, the number of cases actually notified approximating forty. A L.G.B. inspector has been dispatched to inquire into the source of the mischief and to concert measures to prevent its further spread.

DR. JAMES MATTHEW CAW, who only arrived at Berwick last Tuesday to take charge of the local military hospital, was found dead on Saturday morning with his throat cut. He recently returned from South Africa.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

NEW PROFESSOR OF ZOOLOGY FOR GLASGOW UNIVERSITY.

THE King has been pleased to approve of the appointment of Mr. J. Graham Kerr, M.A., of Christ's College, Cambridge, to the Professorship of Natural History in the University of Glasgow, vacant by the resignation of Professor John Young, M.D. Mr. Kerr was educated at the High School and University of Edinburgh, where he passed through so much of the earlier stages in the medical curriculum as had a direct bearing on Zoology, and acted as Demonstrator of Botany under Professor Bayley Balfour. After leaving Edinburgh Mr. Kerr became naturalist to an Argentine Government Expedition to the Gran Chaco, a little known region of tropical South America. The history of that expedition has yet to be written, but those who know it are aware of the part Mr. Kerr played in saving the remnant from utter disaster. It is characteristic of his enthusiasm and devotion to science that, although struggling for bare existence during the greater part of the expedition, which was deserted by its leaders, Mr. Kerr yet made collections and observations which have added to our knowledge of the South American fauna and flora. On returning to England in 1891, Mr. Graham Kerr went into residence at Cambridge, where he graduated, and has since been engaged in zoological research and teaching zoology in the University of Cambridge, where he holds the positions of senior demonstrator in animal morphology and examiner in zoology for the natural science tripos. He is a member of the Publication Committee of the Zoological Society of London, of the Council of the Cambridge Philosophical Society, and is President of the Cambridge Entomological and Natural History Society.

OBJECTIONABLE ADVERTISEMENTS IN RELIGIOUS PUBLICATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Two cases have lately been brought under my observation illustrating the effectiveness of the advertising bait of the infamous quack when displayed to the ingenuous reader in the columns of a religious paper—a subject dealt with briefly in one of your editorial notes of to-day, August 20th. A large number of this class of readers look upon the appearance of an advertisement in a respectable newspaper as a voucher of *bona fides*; and when, as they so often are, paid advertisements are inserted in the form of editorial paragraphs, with no sign to indicate that they are really paid puffs, written by the advertisers, they are doubtless the more effective in driving confiding sufferers into the hands of the quacks. One of the cases I refer to was that of a child, twelve years old, suffering from chronic middle ear disease of six years' duration—a case of deafness through evident destruction of the organ of hearing, and amenable to no treatment affording the faintest hope of restoration of function. Attracted by a puff of a notorious sham "Ear Institution," the parents of the child, in poor circumstances, were defrauded out of a considerable sum for a long series of (of course) perfectly useless visits to the bogus Institution.

The second case was that of a maiden lady, fair, forty, foolish and very fat. She fell into the hands of one of those gentlemen who find it possible to spend several thousands a year on advertising the fact that they possess the secret of an infallible "cure for obesity," for which they charge a merely nominal fee. It has long been a puzzle to know how these gentlemen manage to live by their benevolent vocation. Towards solution of this difficulty a hint was afforded by the case in question; the lady was driven into a condition of nervous excitement bordering upon dementia as a result of the extortion closely resembling blackmail to which she had been subjected. The exact amount out of which she had been defrauded was never exactly ascertained. Cases of this kind are of common occurrence, and could doubtless be narrated by every family doctor throughout the country, so that the nefarious traffic which receives so much effective help from the Press must be in extent altogether enormous. The medical quack is by far the most cynical and cruel of the class of criminals preying upon Society, and having the cunning to keep out of the meshes of the law. He is easily recognisable by any man of the world. It is difficult to form any excuse for a newspaper which lends itself to be his tool.

I am, Sir, yours truly,
August 20th, 1902. G. P.

THE CASE OF DR. RAINSBURY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the Nottingham Assizes on July 17th, Dr Rainsbury, of Skegby, was sued by a collier employed at the Teversal Colliery for damages for alleged unskilful treatment of an injury to his arm, sustained in November, 1900.

The trial resulted in a verdict for the plaintiff for £25 damages and costs. It would serve no useful purpose now to enter at length into the merits of the case, as judgment has been given. From perusal of the report of the trial it appears that Dr. Rainsbury has suffered a great hardship by reason of the judgment.

The expenses of defending the claims were borne by the Medical Defence Union (of which Dr. Rainsbury is a member) but the regulations of that Union do not allow of payment by the Union of any judgment debt and costs which be adjudged against a defendant.

The judgment debt and costs amount to £182 6s. 2d. Dr. Rainsbury has made no appeal to this Union for assistance, but in view of the special nature of the circumstances, and of the apparent injury which he has sustained, the President and Council recommend that a fund be raised by subscription in order to assist Dr. Rainsbury in discharging the judgment debt and costs.

I am accordingly requested to invite subscriptions to this fund.

The matter is most urgent and pressing. I therefore venture to ask that all intended donations be sent to me at the earliest opportunity.

I am, Sir, yours truly,
GEORGE S. O'RORKE,
Secretary, Midland Medical Union.
Nottingham, August 14th, 1902.

THE NOMENCLATURE OF SURGICAL OPERATIONS FOR UTERINE TUMOURS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much interested in reading Dr. Stuart Nairne's letter commenting on the reports of two cases I published in THE MEDICAL PRESS AND CIRCULAR of July 16th and 23rd.

The term "resection" as suggested by Dr. Nairne is, of course, a correct one; but inasmuch as the three operations referred to, namely, the removal of subperitoneal, interstitial, and intra-uterine myomata respectively, are distinct and recognised surgical procedures, it seems to me desirable that they should have distinctive names. If we employ the word "resection," we shall have to speak of abdominal resection of subperitoneal myomata, abdominal resection of interstitial myomata, abdominal resection of intra-uterine myomata. Now these titles are a little long. The resection of a myoma is clearly indicated in the word "myomectomy," which has come into general use. Moreover, although myomata are found in other parts of the body, their occurrence in the uterus is so preponderating that the term "myomectomy," when unqualified, would be universally understood to mean the removal of a uterine myoma.

I readily admit that the names I adopted, namely,

"1. Abdominal myomectomy for cases in which a subperitoneal pedunculated myoma is removed from the uterus,

"2. Abdominal enucleation for cases in which a myoma is shelled out of the substance of the uterine walls,

"3. Abdominal hysterotomy for cases in which the uterine cavity is opened and a myoma removed from its interior,"

are far from being the best that could be used. Indeed, I have not been satisfied with them myself, and have employed them *faute de mieux*. Thinking over the matter lately, I have come to the conclusion that the following terms would be preferable as being more descriptive and not unduly long, namely,

1. Abdominal subperitoneal myomectomy.
2. Abdominal interstitial myomectomy.
3. Abdominal intra-uterine myomectomy.

The word abdominal might be omitted, providing that it were understood that procedures carried out through the vagina were specially labelled "vaginal."

I quite agree with Dr. Nairne that gynæcology is truly a branch of general surgery; but it will be admitted that the uterus in its relation to tumours and their removal practically stands in a category apart from that of other organs, and it appears to me that there is no disadvantage in its having a special nomenclature.

I shall be very interested to hear Dr. Nairne's views on my present suggestions, as well as the opinions of any others who are interested in securing a more satisfactory nomenclature for gynæcological operations.

Two printer's errors in Dr. Nairne's letter require to be pointed out. In line 14, "3. Abdominal hysterectomy" should read "3. Abdominal hysterotomy," and in line 16, for "consecutive" read "conservative."

I am, Sir, yours truly,
Arthur E. Giles.

London, August, 1902.

Literature.

THE THOMPSON-YATES LABORATORIES. (a)

This excellent volume contains fourteen different papers upon a variety of subjects. The opening paper upon The Injury Current of Nerve, by J. S. Macdonald, is the most elaborate article in the volume. It is a most careful piece of work, and the author has taken full advantage of the more recent and extended physical data now available for the physiologist in working out the results of electrical experiments. It is not possible to do more here than merely indicate the nature of the work. It is specially concerned with determining the value and direction of one of the pre-existing factors which plays an important part in the injury current of nerve, viz., the solution which bathes the outer surface of the nerve fibres. Its influence appears to be due to its being a solution of electrolytes, its inorganic salts. The evidence points to the conclusion that the electrical phenomena of nerve depends entirely upon the inorganic salts which it contains. A preliminary communication follows, of much interest, on the cerebral cortex of some of the higher apes, by Grünbaum and Sherrington. Annett, from an experimental investigation into 108 cases of tuberculous expectoration in public thoroughfares concludes that more strict measures must be adopted by sanitary authorities to prevent expectoration, not only in public buildings, but in public thoroughfares, and for the more complete cleansing of these places. Boyce describes a case of pseudo-actinomycosis of the udder of the cow, and Griffith an isolated case of plague. Of more general interest is Hume's paper on a new pathogenic bacillus isolated from a case diagnosed as typhoid fever, with a summary of fourteen similar cases hitherto reported. It differs from the bacillus typhosus not only in not being agglutinated with typhoid serum, but in a number of other characters. It is moreover agglutinated with its own serum, which has no such power over the true bacillus typhosus. It is obvious that a knowledge of this bacillus is an important practical matter. Another subject of great practical importance is the fungus deposit which forms in unfiltered water mains. Boyce has examined the mains which convey the Liverpool water from Lake Vyrnywy, which, owing to a deposit within them, have shown a gradual falling-off in the quantity of water capable of passing through the pipes in the twenty-four hours. Coutts's article on sulphide-producing organisms has a bearing upon the bacterial method of sewage disposal. Physicians will be interested in Little's account of his new nitrometer for the clinical estimation of urea by the hypobromite process. Other articles are extensive focal necrosis of the liver in typhoid, by Glynn; multiple aneurysms of the aorta, by Abram and Dimond; a preliminary note upon a trypanosome occurring in the blood of man, by Dutton; some notes on the embryos of strongylus intestinalis, by Van Durne. This interesting and valuable volume is completed by Durham's report of the Yellow Fever Expedition to Parà, which has already been foreshadowed in various places, and in connection with which the late lamented death of Walter Myers will still be fresh in everyone's memory.

JOURNAL OF OBSTETRICS AND GYNÆCOLOGY. (a)

We have received from Messrs. Baillière, Tindall and Cox the first volume of the new *Journal of Obstetrics and Gynæcology*, which forms a handsome work of close on 800 pages. From the introduction to the volume we learn that the aim of the promoters is to supply a special journal, independent of any society, which will furnish a complete and impartial record of British obstetrical and gynæcological work and a summary of contemporary thought and achievement throughout the world. The volume before us affords ample proof of success in the attainment of this object. Among many interesting and important original communications to its pages we may mention Cullingworth on "Uterine Fibro-myoma," Eden on the "Toxæmic Theory of Pregnancy," and Champneys on "Tubal Gestation," while Drummond Robinson has contributed a lengthy critical review on the bacteriology of the uterus and vagina during labour and the puerperal period. The columns devoted to reviews might, we consider, with advantage be extended, as in a journal of the kind all important works bearing on obstetrics or gynæcology should be noticed. This, however, will doubtless be done in the future. We congratulate the promoters and editors on the success which has attended their efforts.

BACTERIOLOGICAL TECHNIQUE. (b)

This is a useful laboratory handbook of bacteriology. The author's claim that this edition is a considerable improvement upon the first is amply justified. Additions have been made to practically every section of the work, and many new illustrations have been substituted for some of those in the first edition. The illustrations of bacteria are mostly very good and clear, and deserve a special word of praise. Part I. is devoted to bacteriological technique, and many useful methods have been added to this edition. Part II., dealing with the preparation of nutrient media, incubation, inoculation and methods of examining infected animals, air, water, soil, &c., has also had additions made to it. The instructions are necessarily much condensed, and such an important matter as water analysis might, with advantage, have been extended. Part III. deals with the various bacteria pathogenic to man and animals, and also with a number of other bacteria, such as those found in the mouth, in soil, milk, &c., and those concerned in nitrification and phosphorescence. The facts are necessarily given very shortly under definite heads, so as to be easily found, a form which is specially useful to the laboratory worker. Parts IV. and V. deal with fungi and yeasts, while the last parts, viz., VI. and VII., deal with the protozoal organisms of malaria, &c., and the very minute organisms of African horse sickness, pleuro-pneumonia, &c., which are so small that they pass through bacterial filters. These parts are all brought well up to date, the more important literature of recent times bearing upon them having received attention from the author. Altogether the book will be found to be a useful and trustworthy help by the laboratory worker in bacteriology.

(a) "Journal of Obstetrics and Gynæcology of the British Empire." Vol. I., January to June, 1902. London: Baillière, Tindall and Cox. Pp. 713.

(b) "Manual of Bacteriological Technique and Special Bacteriology." By Thomas Bowhill, F.R.C.V.S., F.R.P.S. Enlarged Second Edition. Revised, with numerous original illustrations. Edinburgh: Oliver and Boyd. London: Simpkin, Marshall, and Co., Limited. 1902.

HARE-LIP AND CLEFT PALATE. (*a*)

Surgeons attached to general hospitals as a rule do not go out of their way to operate on cases of hare-lip and cleft palate, as the trouble is very great and the results are very often disappointing. The author speaks of the difficulty, and says, "I know of few operations in surgery in which it is so difficult to obtain a really good result as in an operation for hare-lip." If this is true of hare-lip it is certainly true of cleft palate. These subjects are carefully considered in the work before us. Some excellent photographs before and after operation are also included, and any surgeon who wishes to specially study this subject will find the information given very useful.

HEATH'S CLINICAL LECTURES. (*b*)

We have carefully perused this volume, which teems with practical information on a variety of surgical subjects comprising seventeen lectures which the author states are a collection of clinical lectures delivered by him in University College Hospital during the last few years, and he has also included two of the Lane Lectures delivered in the Cooper Medical College, San Francisco, in 1897, and the Hunterian Oration, delivered in the Royal College of Surgeons in the same year. The lectures are all interesting and the subjects well chosen and practical.

WATER AND ITS PURIFICATION. (*c*)

Dr. Rideal's writings are always interesting, and the book before us is certainly no exception. The subject of water purification is, as the author points out in the preface, one of supreme importance to all classes of the community, and it is a matter of regret (in face of the obvious lesson to be learnt from recurrent epidemics of water-borne disease) that it receives so little attention from many local authorities.

In the book before us every phase of the subject is treated in a masterly fashion. Practically nothing of importance is omitted. Sources of water, impurities, storage, distribution, purification and analysis are all dealt with in a manner which leaves little scope for criticism, while by no means the least valuable portion of the work will be found in the appendix, which contains a short history of some recent epidemics, together with suggestions for future legislation. Brightly and succinctly written, its pages are never dull, and teem with information of a most useful and practical description. The illustrations, too, are numerous and instructive, though it is to be regretted that Figures 28 and 29 have been omitted. The book should be read and followed by all persons having charge of water supplies, and might be placed in the hands of all local authorities with advantage both to themselves and to those over whose sanitary destinies they preside.

Medical News.

A Medico-Legal Anomaly.

In 1895, a girl, then 17 years of age, was accidentally struck by the bullet of a saloon rifle, the missile remaining in the brain. She recovered from the injury, but since that time she constantly complained of headache and uncomfortable symptoms in the head. Last week she died somewhat suddenly, and at the autopsy an abscess of the brain was found to have formed around the bullet. At the inquest the jury were directed that they had not to inquire into the circumstances under which the injury was inflicted, the law assuming that when death takes place more than a year and a day after the occurrence it is due to some other cause. In accordance with this direction the jury returned a verdict of death from natural causes, which is a tax on one's credulity.

The Fourteenth International Medical Congress.

Arrangements have been concluded with the various railways of France and Spain by which members of Congress will be allowed a reduction of 50 per cent. on the price of tickets. The Spanish and Italian navigation companies have also consented to a reduction, the former of 33 and the latter of 50 per cent. on the usual fares. An office has been opened at Madrid to provide visitors with suitable lodgings, and communications relating thereto should be addressed to the "Bureau des Logements," Faculté de Médecine, Madrid. The subscription (30 pesetas or 23 francs), may be paid either direct to Madrid or to the local secretaries.

A Difficult Diagnosis.

A few days since, at York, a lad of seven, after eating some berries plucked from a shrub near the school, fell ill, and was taken to the hospital, where "the usual remedies were applied," He died soon after, and at the autopsy it was found that death was really due to fracture of the skull. Inquiry elicited the fact that the lad had fallen from a wall while playing with his schoolfellows, when no doubt the injury was inflicted. The case is an instructive one as showing how necessary it is always to keep an open mind, whatever history the friends may give of the occurrence.

Washing Liquor for Lime Water.

A child, æt. 4, died at Bradford last week in consequence of washing liquor having been given in mistake for lime water. Washing liquor, we may recall, is made by boiling lime with soda and contains caustic soda. It is therefore obviously a liquid which ought only to be sold in bottles of a special shape and duly labelled "poison."

The Ætiology of Cancer.

The Spanish official *Gazette* has published a decree appointing a Commission consisting of the following Spanish physicians:—Ustariz, Bravo Coronado, Cervera, and Jiménez, to investigate the ætiology of cancer, and with them is associated Hans Leyden, physician to the German embassy in Madrid. The Commission will work under the control of the Public Health Minister, Señor Pulido, formerly of the editorial staff of *El Siglo Medico*, one of the most enthusiastic sanitarians in Spain. The co-operation of the medical schools and of private practitioners is solicited. The work of investigation will be carried on in connection with that being undertaken in Berlin.

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, August 16th, 1902, represent an annual rate of mortality of 20·0 in every 1,000 of the population. There were 20 deaths from measles, 19 deaths from diseases of the nervous system, 21 deaths from diseases of the circulatory system, and 19 deaths from diseases of the respiratory system; 55 infants died during the week, of whom 27 were under one year old. Within the city the death-rates in the following districts were as follows:—Castle Street district, 45·7 Blackhall Place, 37·9; and Clarence Street North, 23·9.

(*a*) "Hare-lip and Cleft Palate." By R. W. Murray, F.R.C.S., Surgeon David Lewis Northern Hospital, Liverpool, late Surgeon Liverpool Infirmary for Children. Pp. 29. Price 3s. London: J. and A. Churchill. 1902.

(*b*) "Clinical Lectures on Surgical Subjects," delivered in University College Hospital. By Christopher Heath, Past President Royal College of Surgeons, England, Surgeon to University College Hospital. Second Series. London: J. and A. Churchill. Price 6s. Pp. 343. 1902.

(*c*) "Water and its Purification." By Samuel Rideal, D.Sc. Lond., &c. Pages xvi. and 346. Second Edition, revised and extended. London: Crosby Lockwood and Son. 1902.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

COOK'S METHOD OF URIC ACID ESTIMATION.

To 10 c.c. of urine add 0·5 to 1·0 gms. of sodium carbonate and ammonium hydrate 1·2 c.c. Centrifugate and pour clear urine into tube. Add and mix ammonium hydrate 2 c.c., sol. ag. NO_3, 5 per cent., 2 c.c. Centrifugate. Again add ammonia, and the solution is centrifugated till the minimal reading is obtained. One c.c. of ppt. represents 0.001176 gm. of uric acid in 10 c.c. urine, and the percentage is obtained by multiplying the total amount by 10.

H. O. V.—"Manquee," a disease which attacks young cattle in South America, is credited with being due to the very smallest microbe yet discovered. It is much smaller than the bacillus of influenza, and can with difficulty be seen under a magnification of 1,500 diameters.

REMARKABLE SYMPTOMS.

"Well, Patrick," asked the doctor, "how do you feel to-day?" "Och, doctor, dear, I enjoy very poor health, intirely. The rheumatics are very distressin' indade; when I go to slape I lay awake all night, an' my toes is swelled as big as a goose hen's egg; so whin I sthand up I fall down immajit."

H. A. R.—We do not see that any useful purpose is likely to be served by publishing your letter, especially as the question is now virtually settled for good or ill.

TURPENTINE AS A DEODORANT.

Smilax.—Cases of prostatic enlargement associated with dribbling of urine, attended with the usual obnoxious smell, are offensive to strangers and the source of much misery to the patients themselves. A small quantity of pure spirits of turpentine sprinkled on the patient's dress and on the bedclothes will act as a good deodorant, counteracting the urinous smell to a remarkable degree.

Dr. Radley.—The course you propose does not appear to be open to objection, but you must be careful to avoid any misunderstanding on the part of the patient. The alternative proposal cannot be for a moment entertained.

THE HONORARY F.R.C.P. LOND.

In reply to our correspondent, "F.R.C.P.Edin.," the honorary Fellowship of the R.C.P. of London was conferred on H.M. King Edward VII. about four years ago, in recognition of the great interest always evinced by him in the medical profession, especially in connection with the Prince of Wales Hospital Fund. We believe his Majesty is the only layman on whom this distinction has been conferred.

Appointments.

Bennett, J., M.B., Ch.B., B.A.O.R.U.I., Medical Officer of Health for the Borough of Hyde, Cheshire.

Coaker, F. W. J., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Bromsgrove Rural District.

Ewart, David, M.B., Ch.B.Edin., F.R.C.S.E., Honorary Surgeon to West Sussex, East Hampshire, and Chichester General Infirmary.

Fenton, W. R., B.A., M.B.Univ.Dublin, Acting Principal Medical Officer in Mashonaland during the absence on leave of Dr. Fleming, C.M.G.

French, G. W. H., F.R.C.S., Assistant Surgeon to St. Paul's Hospital for Skin and Genito-Urinary Diseases, Red Lion Square, W.C.

Hill, W. J., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health to the Cleveland Urban District Council.

Jenkins, G. H., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer of Health to the Usk Urban District Council, Mon.

McGachen, Fred Wm. Dobson, M.D., D.Ph.Lond., Medical Officer to the Weymouth and Westham District, and Public Vaccinator of Weymouth and Melcombe Regis, vice Dr. E. N. Pridmore, M.B.Lond., resigned.

Peacock, W. E., M.D.Durh, Medical Officer of Health to the Felling Urban District Council.

Steinhauser, J. R., M.B., B.Sc.Lond., Medical Officer for the Borough of Lewes.

Walker, J. W. Thomson, M.B.Edin., F.R.C.S., Assistant Surgeon to the North-West London Hospital.

Vacancies.

Bethnal Green Infirmary.—Assistant Medical Officer. Furnished apartments, board, and washing provided. Salary £100 per annum. Applications to the Medical Superintendent of the Infirmary, Cambridge Road, N.E.

Bristol General Hospital.—Medical Officer for the Cottage Hospital at Avonmouth and Contractors' Sick Club. Salary £250. Applications to the Secretary, Bristol General Hospital, Bristol.

Cancer Hospital, London.—Pathologist. Salary £250 per annum. Applications to the Secretary at the Hospital, Fulham Road, S.W.

Cardiff Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, washing, and furnished apartments. Applications to Leonard D. Rea, Secretary and General Superintendent.

Carrigbyrne Dispensary District.—Medical Officer. Salary £100 per annum, together with the usual vaccination fees, and also £15 per annum as Medical Officer of Health. Applications to P. A. Pope, Clerk of the Union. (See advt.)

Cheltenham General Hospital.—Assistant House Surgeon. Salary £112 per annum, with board, lodging, and washing. Applications, with copies of testimonials, to be sent to the Honorary Secretary and Treasurer, General Hospital, Cheltenham.

City (Fever) Hospital, Aberdeen.—Resident Physician. Salary £100, with board and rooms. Applications to the Medical Officer of Health, City Buildings, Aberdeen.

City of Sheffield.—Second Assistant Medical Officer at the City Hospitals. Salary £120 per annum, with board, lodging, and attendance. Applications to H. Sayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

County of Lanark.—District of the Middle Ward.—Resident Physician. Salary £140 per annum, with board, &c. Applications immediately to J. B. Ferguson, District Clerk, District Offices, Hamilton.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing. Applications to W. Vaughan Jones, Secretary.

Middlesex Hospital, W.—Medical Officer. Salary £150 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

Parish of Birmingham.—Workhouse Infirmary.—Assistant Resident Medical Officer. Salary £100 per annum, with furnished apartments, rations, coal, gas, laundry, and attendance. Applications to Walter Bowen, Clerk to the Guardians, Parish Offices, Edmund Street.

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £120 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

Tadcaster, Goole, Riccall, and Selby Rural Districts, and Selby Urban District.—Medical Officer of Health. Salary £120 per annum. Applications to E. Townend, Clerk to the Joint Committee, 1, Abbey Place, Selby.

Births.

Jones.—On Aug. 24th, the wife of E. Lloyd Jones, M.D. (Camb.), Corpus Buildings, Cambridge, of a daughter.

Ward.—On Aug. 21st, at 22, Museum Street, Ipswich, the wife of Francis Ward, M.D., of a daughter.

Deaths.

Jeaffreson.—On Aug. 22nd, at Stanmore, Frances, widow of Henry Jeaffreson, M.D., and lately of 14, Southwick Crescent.

Murphy.—On July 27th, at his residence, the Simmer and Jack Hospital House, Germiston, Transvaal, G. Wyndham Murphy, M.D., aged 51 years. Deeply regretted.

Rodwell.—On Aug. 21st, at Loddon, Norfolk, on the eve of his 50th birthday, Edward Manby, M.R.C.S., L.S.A., second son of the late George Rodwell, surgeon, of Loddon.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m. Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. A CASE OF MALIGNANT ENDOCARDITIS, WITH HEMIPLEGIA AND EMBOLISM OF ONE ILIAC ARTERY. (a)

By GEORGE CARPENTER, M.D.LOND.,
Physician to the Evelina Hospital for Sick Children.

ARTHUR E——, æt. 7, had a strong family history of tuberculosis, and his brother, at the time of his illness, was in the Evelina Hospital suffering from tuberculous dermatitis, and died, whilst an inmate there, of morbus cordis.

The boy Arthur had been quite healthy, with the exception of an attack of measles, till July 4th, 1901, when a rash was "noticed all over him," and he was feverish; there was neither sore throat nor sickness. He was seen for the first time on July 11th in the casualty department of the Evelina Hospital, on which occasion "his right leg was bent at the knee, and stiff, and the knee-jerk was exaggerated on this side." A systolic mitral bruit was heard, which was conducted into the axilla, and he was short of breath.

On July 17th he was taken ill suddenly whilst at play. He came indoors to his mother, complaining of headache, and was put to bed. Almost immediately he had a fit, and became unconscious. He twitched in the fit all down one side, but which was not certain, and he remained unconscious until he was admitted to the Evelina Hospital on the following day, when he was found to be twitching on the *left* side.

On admission on the 18th he was comatose, his eyes were sunken, his lower jaw relaxed, and his left side paralysed, the lower half of the face being involved. The knee-jerk was absent on that side, but it was present on the right, the arm and leg of which he moved freely. There were no convulsive movements. The right pupil was widely dilated, and did not react to light; the left reacted, though badly. The cardiac impulse was in the sixth interspace, 1½ ins. outside the nipple line, and unaccompanied by extension of dulness to the right; but there was some epigastric tenderness. A loud systolic mitral bruit was audible, which was conducted into the left axilla. The lungs were normal. The liver and spleen were not enlarged, and the urine was free from albumin. The pulse was slow, weak, and irregular; the breathing was also slow, and occasionally sighing. Sweating was profuse and general. The temperature by the rectum was subnormal. The abdomen was sunken (scaphoid), and tender to the touch. He was sick twice during the day.

July 19th.—He was very sick during the early part of the night, after which his left arm was rigid for a time, and the other limbs were slightly so. He subsequently vomited half a dozen times. During the day "he moved all his limbs," and there was no rigidity. He was semi-conscious, and very irritable when disturbed. The pulse was very slow, but less irregular, and the pupils were not so unequal. A note on the 20th stated that during the night he moved the right side of his body more than the left, and his left leg was at times rigid. He continually drew his right hand across his forehead, and was still very irritable when disturbed. The pulse was slow and irregular; the pupils as before; and during the day the general condition was much about the same. His temperature, which had all the time been subnormal, rose to 100° F., and on the 21st it was 102·2° F. The fundus oculi was examined, as it was thought he was developing tuberculous meningitis, and marked optic papillitis was discovered. The sickness had ceased. He did not resent being disturbed. The arms and legs were rigid at times, the hands clenched, and the eyes fixed, and occasionally there were muscular twitchings. The pulse was rather quicker, but still weak and irregular, and he was more feeble. He had been fed by the nasal tube, which was still being used. On the 22nd he had been very quiet all night, his hands were clenched and his limbs rigid, and he occasionally drew up his right leg. The abdomen was very scaphoid. During the day he scarcely moved at all, his hands were still clenched, and the limbs occasionally rigid. On the 23rd he had passed a peaceful night, and was quiet all day, occasionally moving his right arm over his head. On the 24th he had been very quiet all night, and slept with his eyes half closed until the early morning, when he commenced to groan and scream, and drew his right hand across his forehead; this lasted for about an hour. He now took a little food by the mouth, and appeared to understand when spoken to, but he was unable to speak. He could not open his right eye (ptosis), but the left was constantly open. The left side of the body was rigid, and he moved his right leg and arm quite easily. The pulse was still weak and irregular. His temperature had been gradually falling, and on this day was once more sub-normal. On the 25th, during the early part of the day, he was quietly sleeping, but in the evening he cried out and drew up his right leg, and put his right hand to the right side of the head, as if in pain. He was unable to move the left side. On the 26th he occasionally cried out and drew up his right leg. He could open his right eye a little wider. He constantly rubbed the right side of his head. He was fed partly by the nasal tube and partly by the mouth. His general condition was much about the same. On August 1st he was quite conscious all day, and talked incessantly. He frequently waved his right leg, and his right eye was more open. He moved his left arm a very little, and the knee-jerk on the left side had returned, and was increased. On August 6th the optic discs were swollen, about 3 D., and the vessels were in places partly buried in exudation. A little more than the swollen diameter of the optic disc distance in the left eye, in the upper and inner quadrant, was a small pear-shaped patch of a light fawn colour. It had to be carefully looked for by the direct method, as the difference in colour tone between it and the red reflex was not so marked as to make it appear a *very* staring feature, though quite striking enough; but by the indirect method it stood out well, and readily attracted my attention. I considered it to be tubercle in the choroid, though, in my experience, its shape was not quite classical, and perhaps it was not quite obtrusive enough; but, apart from these criticisms, it was very like indeed, and I was quite prepared to accept it as a tubercle, and did so, founding a diagnosis of tuberculous meningitis on my discovery. (*a*) The optic papillitis was the pronounced variety usually associated with cerebral tumours, and I thought it possible he had a cerebral tuberculous tumour and secondary tuberculous meningitis. He could not now move his right eye in any direction, and he could only look towards his nose with his left eye.

(a) Read before the Society for the Study of Disease in Children, on Friday, April 18th, 1902.

August 12th.—Since August 1st he has had a good appetite, and has slept satisfactorily. He is beginning to move his eyes a little more; both external recti are paralysed now. There is loss of tactile sensation below the left knee, and diminished sensation over the whole of the left arm. The temperature up to this date has been either normal or subnormal; there have been one or two trifling rises, but they have not exceeded 100° F.

15th.—Movements of the left arm and leg have greatly improved. In the former there is an all round improvement, and in the latter they are best at the hip-joint. The knee-jerk is exaggerated, but knee-clonus cannot be obtained; there is, however, ankle-clonus. Sensation to pain is normal. Tactile sensation is much better in the leg. In the arm tactile sensation and sensation to pain have improved. The lungs, spleen, and kidneys are normal. There is now paresis of the right external rectus, and a linear hæmorrhage on the outer side of the right optic disc. Towards the periphery of the inner hemisphere of the left fundus, there is some faint diffuse pigment.

29th.—The boy is still rather sleepy-looking, and he is pale. The left side is weaker than the right, but there has been marked improvement in the paralysis since massage was commenced on August 9th last. He has recovered from the facial paralysis and the ocular movements have become natural. The knee-jerks on both sides are brisk, being most marked on the left. Sensation is now normal.

September 2nd.—The tubercle-like body in the left fundus oculi is more defined than has previously been the case. In the inner hemisphere in the periphery is a small bunch-of-grapes-like hæmorrhage, in which two minute retinal vessels terminate. Above this, and to its central side round pigment-granules are freely sprinkled over a limited area.

6th.—It was decided to inject the boy with tuberculin. Subsequent to August 12th his temperature began to rise little by little, the highest point reached being 102·4° F.; it was intermittent. In the morning it was subnormal, usually somewhere between 97° F. and 98° F., and in the evening mostly between 100° F. and 101° F.; sometimes more and sometimes less. The pulse during the subnormal stages varied between 96 and 112 beats to the minute, and during the rises of temperature between 112 and 160 beats to the minute. In the apyrexial periods the respirations varied between 20 and 36 to the minute, and during the pyrexial between 32 and 56 to the minute. Tuberculin (·003 c.c., supplied by the British Institute of Preventive Medicine) was injected at 2 p.m., when his temperature was 98·6° F.; at 4 p.m. it had reached 101·4° F, and by 6 p.m. was 101·6° F., and at 12 p.m. 99·8° F. Apart from the rise of temperature, which was but slightly in excess of what had already happened, nothing occurred. The fundus oculi was unaffected by it. A trace of albumin, unconnected with the injection, was found in his urine to-day; it had been tested on many occasions previously, and had always been found natural.

For the past three weeks (October 20th) the temperature has been oscillating, usually remittent, and latterly sometimes intermittent. It has but once fallen below the normal during the first two weeks. For the first week it mostly varied between 101° F. and 103° F. for the highest rises of temperature, and for the remaining two weeks between 101° F. and 102° F. For the last week it has often fallen to subnormal, and has but once exceeded 101° F. On the 22nd he was moaning and coughing frequently during the night, and he complained of pains in different parts of his body.

November 18th to the 26th.—He was very sick once during the night on the 18th. Between these dates slight traces of albumin were found in his urine. He was sleeping well, and taking his food satisfactorily, but was occasionally sick. On the 22nd his eyes were examined, and his optic discs were found to be turning white. There was no obvious squint or defect in the extrinsic muscles; the pupils were semi-dilated, and almost without direct action to light. For a month or more the temperature has been oscillating, and has been more often remittent than intermittent, it has only twice been over 102° F., and on many occasions it has been subnormal.

December 1st.—He slept well. All the morning he was very drowsy, and took his dinner with persuasion. At 1.20 p.m. his left arm and leg became convulsed, and he became unconscious. The pupils were unequal, the right being larger than the left. This condition continued until 2.45 p.m., when he was sick, since when he gradually returned to consciousness, but he was unable to speak. He was very restless, and constantly sat up in his cot, and cried out as if in pain. At 5.30 p.m. he asked for drink, and his speech gradually became quite distinct. He then complained of much pain in his head and abdomen.

On the 2nd he was drowsy and difficult to rouse. He complained of headache, and there was slight facial paralysis (incomplete) on the *right side* (?). The left arm was decidedly weaker than the right. The knee-jerks and clonuses were as before, and the legs were painful. Speech was very tremulous. slow, and almost unintelligible at times. The lips were blanched.

11th.—He slept well during the night of December 11th, but from 7.30 a.m. he was continually turning from side to side, or sitting up in his cot. His breathing was laboured, and his alæ nasi dilated. The face and lips were cyanosed. and many coarse crepitations were audible over the bases of both lungs. The pulse was barely perceptible, and his extremities were cold. He was continually muttering and screaming, and gradually his speech became quite incoherent. His pulse was then imperceptible,

---

(*a*) *Vide* "Tuberculosis of the Choroid." By George Carpenter, M.D., and Sydney Stephenson, C.M. Illustrated by coloured plates. Reports of the Society for the Study of Disease in Children Vol. I., pages 169 to 181. 1901.

and at 1.55 p.m. he was slightly convulsed, and died five minutes later, having been in hospital for 145 days. There was but little, if any, alteration in the character of the fever until within a week of his death, when 99·8° F. was the highest point registered, and the temperature was for the most part subnormal.

Post-mortem Examination.—Brain.—The pia mater was much injected with blood-stained effusion over the whole surface of the brain. The convolutions were flattened, and much blood-stained fluid escaped on removing the brain from the skull. The base of the brain was covered with a hæmorrhagic gelatinous exudate, as was the vertex. There was no thickening of the pia mater, or any sign of tubercles along the vessels. The posterior part of the right cerebral hemisphere from the fissure of Rolando almost to the tip of the occipital lobe was considerably depressed. On opening the brain this depression was seen to be due to a "cyst" about the size of a walnut which was present in this region, extending forwards to about the middle of the lateral ventricle, and backwards to the limits of the posterior cornu of the ventricle. Greenish fluid with broken down brain substance was present in this "cyst," which was separated from the posterior cornu of the ventricle by a thin partition of white matter. The ventricle itself was somewhat dilated, but otherwise looked healthy. Behind this cystic area the white matter was more solid, but dark reddish-grey and dirty-looking—evidently necrotic. A great part of the white matter of the right occipital lobe was involved in this necrosis, as was also a small area of the grey matter of the posterior parietal convolution. The middle cerebral artery was carefully examined for an embolus, but it could not be found. Presumably the necrosis and softening which ensued had involved the region of the embolism, and so obliterated any trace of it. The rest of the brain was normal.

Respiratory System.—The respiratory system was practically normal, except for a doubtful infarct in the upper lobe of the left lung. No emboli could be found in the pulmonary arteries.

Circulatory System.—The heart was considerably enlarged, and a few petechiæ were present on its surface. The right auricle was healthy; the tricuspid orifice dilated. The right ventricle was hypertrophied and the valves healthy. The left auricle was dilated and its wall hypertrophied. On looking into it, the mitral orifice was found narrowed so as to admit a cedar pencil, the narrowing being due to the presence of a mass of "warty" vegetations projecting into the cavity of the auricle from the mitral valves. The left ventricle was much dilated; its wall was not much hypertrophied, and it was thinned near the apex. Projecting down from the mitral orifice into the ventricle was a large mass of vegetations, many of them a quarter to half an inch or more in length, and ribbon like, being attached at one end, and otherwise hanging free in the cavity. On cutting open the mitral orifice the opposed and auricular surface of the cusps were seen to be covered with sessile and pedunculated vegetations Large numbers of streptococci were seen in stained sections of these vegetations. The rest of the ventricle and the aortic valves were normal. The aorta, the left common iliac, and the external and internal iliac arteries were healthy. At the bifurcation of the right common iliac artery was a firm embolus which had eroded, and was closely adherent to, the walls of the artery. Spreading up from this embolus was a firm, decolourised, antemortem clot, more than an inch long, occupying nearly the whole length of the right common iliac artery. A small red clot (possibly post-mortem) extended down into the right external iliac artery from the embolus at the bifurcation of the common iliac. The internal iliac artery on the right side was occupied by a clot about one inch long and decolourised; it was breaking down and almost purulent. A piece of the embolus at the bifurcation was stained for organisms, and showed streptococci. The adjacent right common iliac vein contained a long dark clot (post-mortem clot) and its walls were apparently healthy.

Alimentary System.—The œsophagus, stomach, and intestines were normal, except for many small, circular, red patches in the small intestine; these were either small submucous hæmorrhages or hæmorrhagic solitary follicles. The spleen and kidneys showed many infarcts, recent and old. The liver was large, somewhat pale and soft, but otherwise normal. The other organs were apparently healthy.

Microscopical sections of the eyes were prepared by Mr. Sydney Stephenson, and it was found that the fawn-coloured patch in the choroid was not a tubercle, and that there were subretinal hæmorrhages, proliferation of the retinal pigment, and considerable optic papillitis, as detected during life with the ophthalmoscope.

METHODS OF UNITING DIVIDED INTESTINE WITH SPECIAL REFERENCE TO A NEW BONE BOBBIN FOR THAT PURPOSE. (a)

By E. STANMORE BISHOP, F.R.C.S.Eng.,
Honorary Surgeon, Ancoats Hospital, Manchester.

There are four classes of methods whereby the divided intestine may be reunited:—

First, by simple suture.

Second, by suture over instruments which are removed at the time.

Third, by suture over absorbable material, which is allowed to remain.

Fourth, by metallic couplers, also left *in situ*.

Suturing is done in all but the fourth class, and even in this two purse-string sutures are required.

Simple suturing is liable to be imperfect and to leave gaps by means of which leakage may occur. Besides, it is far more difficult, and almost of necessity is associated with more handling of the gut than any of the other plans.

Suture over instruments is neater, more likely to be complete, but the uniting surfaces are left with no protection during the plastic stage of union, the fæcal stream being allowed to pass over it in actual contact.

Metallic couplers are quick in application, and are likely always to be required when time is an imperative factor in the case; but they are heavy, tend to kink the bowel, sometimes produce necrosis which is not limited to the parts compressed, and their removal after their work is done does not always take place without a further interference.

The method of suturing over absorbable substances is an old one, and much ingenuity has been expended upon it. It dates from that known as the method of the four masters, in which a piece of trachea or dried gut was used. The bone plates of Senn, the raw hide of Byrom Robinson, and the various substitutes made of potato, carrot, &c., are all modifications of this. The representatives, however, of this class at present in use are mainly three—the bone bobbins of Jessett, Allingham and Robson.

A really good bobbin should have six characteristics. It should be:—

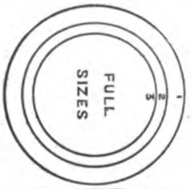
(a) Abstract of paper read before the British Medical Association at Manchester, July-August, 1902.

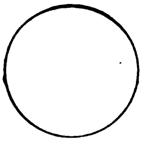
First, easy of introduction.

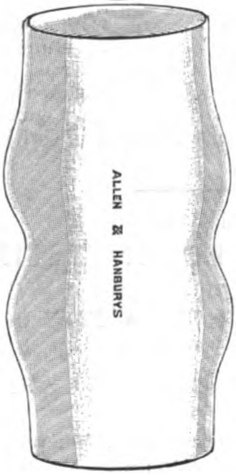
Second, perfectly simple, requiring no elaborate technique.

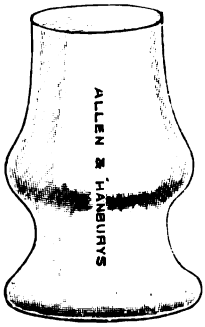
Third, resistant at first, absorbable later.

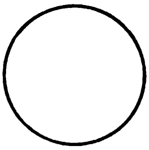
Fourth, so formed that the purse-string sutures which fix the intestinal ends upon it should approximate the two ends by the same movement as that by which they are fixed.

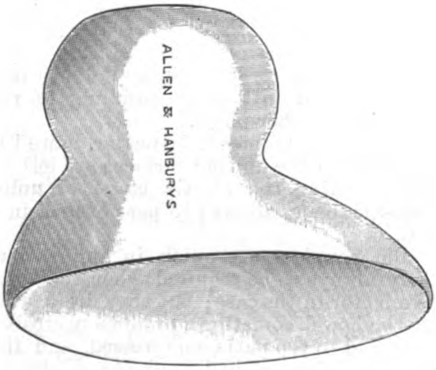


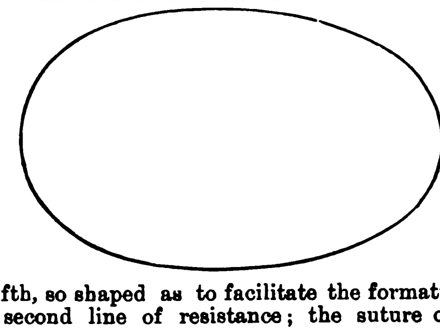












Fifth, so shaped as to facilitate the formation of the second line of resistance; the suture of the folds of gut outside the purse-string suture.

Sixth, of such a character as to protect the line of suture during the stage of plastic union.

Jessett's bobbin is easy to introduce, but it is in two pieces, each of which require separate fixation to the bowel end. A species of intussusception is produced which may persist and increase later. The fourth requirement, so admirably arranged for in Allingham's bobbin, is not possible with it.

Allingham's fulfils this well, but it is far more difficult to introduce, and if such a size is chosen as to suit the central point, which determines the future lumen of the gut, the ends of the bobbin unduly stretch the bowel above and below, and so increase the risk of post-operative necrosis.

Robson's bobbin makes no attempt to fulfil the fourth requirement, and the space between the two ends is too great to permit of the steadiness in fixation of the gut, so useful in making the secondary suture, and which is found in Allingham's model.

The bobbin which I show, and which has been made for me by Messrs. Allen and Hanbury, is based upon a combination of the main features of both Jessett's and Allingham's. It aims at obtaining the ease of introduction of the former whilst retaining the principle of the double inclined plane, so distinctive of the latter.

But no one form of bobbin is exactly suited to all the various operations now practised on the intestinal tract, and for which they may be needed. So although in all, as will be seen, the same underlying principle is present, each one of the three forms is modified to permit of its use in different positions. The first is for use in simple end-to-end union, but, though eminently useful in this, it is evident that if this were used in ileocolostomy the end which was in the colon would be too long, and would tend to obstruct the passage of matters in its lumen. In the second form that is avoided by simply truncating this end just beyond the highest point of the inclined plane on this side. The interior is flared to some extent so as to direct the fluid coming through from the small intestine away from the line of union between that gut and the colon. Although this form would do for pylorectomy, yet this the third fulfils the indication of that operation more perfectly. Experience has shown that the point most likely to yield and to permit extravasation is that at the junction of the vertical and circular lines of suture. The gastric end of this bobbin is therefore widely flared, so as to protect this more completely, whilst although the whole shape of the appliance is thus apparently greatly altered, it will, I think, be evident that the main principle is still preserved.

In all, the apposing surfaces are united to the bobbin by purse-string sutures, which approximate the two ends by the same movement as that by which they tighten them. In all a fold of intestine on either side just beyond is lifted up and rendered more easily available for the second line of suture. In all, the line of union is well protected from the fæcal circulation until it is safely and firmly united. And in all the introduction of the bobbin is rendered as easy as possible.

Death Under Chloroform.

A death under chloroform is reported from the Liverpool General Infirmary, the victim being a woman, æt. 34, who was about to undergo an operation for enlarged thyroid gland. She died suddenly, before the operation had been commenced, although the gland in nowise interfered with respiration. The usual verdict was returned. An omnibus conductor also died under chloroform last week at Guy's Hospital prior to undergoing an operation.

THE DIFFERENTIAL DIAGNOSIS OF FUNCTIONAL AND ORGANIC PARALYSIS. (a)

By THOMAS BUZZARD, M.D., F.R.C.P., Lond.
Consulting Physician to the National Hospital for the Paralysed and Epileptic.

Dr. Buzzard remarked that the expression "functional," as employed in this country, is scarcely ever met with in the writings of Continental authorities, where cases of the class so termed by us are always called "hysterical."

Without attempting to define the word, he thought that, for the purposes of the discussion, it would be convenient to consider it as applied to cases of paralysis which simulated more or less closely those arising from structural alterations of recognised character, within or of the nervous system, without being dependent upon any that the most advanced means of investigation enable us to distinguish.

He also thought that the term should be limited to cases of paralysis of a kind which it would be possible for at least some healthy persons to produce by voluntary simulation. This was not to imply that they are so produced (he entertained no doubt about the reality of the disorder), but in order to exclude from the category such examples as paralysis confined to the district of a single nerve-root or trunk of a mixed nerve. Functional paralysis could sometimes (though by no means always) be removed rapidly or suddenly as a result of persuasion or physical or moral shock.

He enumerated many symptoms which were conclusive as to the existence of organic disease, and thought that, on the other hand, there were probably none which, unsupported, could be relied upon to establish a diagnosis of functional paralysis.

Functional hemiplegia was rarely preceded by anything resembling apoplectic seizure; it was most commonly of somewhat gradual onset, and was principally differentiated by its failure to present that gradual passage from flaccidity to contracture which was characteristic of the organic form. It was prone to be associated with an amount of anæsthesia far exceeding that usually observed in organic hemiplegia, except of that form in which there is lesion of the sensory tract in the internal capsule. The points of difference between organic and functional hemianæsthesia were considered.

Reference was made to the characteristic hysterical gait. This had been well described by Todd, to whom we owe also the observation that hysterical hemiplegia rarely, if ever, attacked the face. Apparent exceptions to this experience were described.

Attention was drawn to Babinski's "flexion combinée de la cuisse et du tronc" as an important test. In organic hemiplegia an effort to sit up in bed without the aid of the arms causes the heel of the affected side to be lifted, which does not happen in the functional form.

Although a process of slow and gradual contracture is not prone to occur in the course of functional hemiplegia, a strong contracture (without previous flaccidity) may take place, often suddenly, and present a very marked *primâ facie* resemblance to that which results from an organic lesion. In such circumstances a point which he (Dr. Buzzard) had described many years ago, was useful for differential diagnosis. In true hemiplegic contracture of long standing, he had pointed out, the whole arm cannot be passively extended at one moment, but in the functional form, the arm, hand, and fingers can all, by an effort, be brought into one plane.

He did not think that inequality of the deep reflexes on the two sides could be absolutely relied upon to prove that the hemiplegia was of organic origin, although it was without doubt a very strong indication in that direction, and the same might be said of ankle clonus, which was sometimes, though very rarely, in the functional form indistinguishable from that depending upon organic lesion. Dr. Buzzard said that the experience of many years had entirely confirmed an observation published by him some twenty years ago as to the absence of, or at least difficulty in, eliciting plantar reflex in functional paralysis, and he thought the symptom was of great service as a negative sign in differentiating functional from organic paralysis. The "toe phenomenon," described by Babinski in 1896, was probably of still more importance, since it gave positive evidence of organic disturbance. Monoplegia of functional origin was then discussed, and it was shown that although in many cases the character of the affection could be conclusively demonstrated, its differentiation might sometimes present insurmountable difficulty. Paraplegia he thought rarely presented any serious difficulty, especially because of the aid to diagnosis afforded by the Babinski toe phenomenon and his own symptom of absent plantar reflex. Some remarks were made on the electrical condition sometimes observed in muscles in cases of functional paralysis, which might tend to cause misapprehension, and the various signs indicating functional paraplegia were described.

Some remarks on the comparatively moderate and oftentimes transitory paralysis of a limb or limbs in insular sclerosis concluded the address. Attention was drawn to the extreme frequency with which this was erroneously regarded as of functional character, and how much deplorable injustice was thereby inflicted on the numerous sufferers from this disease. He combated the idea held by some that these attacks of localised paralysis were at first hysterical and eventuated in organic change, and expressed the opinion that it was the attack of structural disease in the central nervous system which incidentally caused also hysterical symptoms. Not only physical shock, but the shock of structural disease was prone to induce, along with its immediately resulting symptoms, others of a functional and often transitory character. In conclusion, he pleaded for the medical student receiving accurate instruction and study of the Babinski toe phenomenon as a most important means of differentiating organic from functional paralysis.

THE VALUE OF THE IMPERFECTLY DESCENDED TESTIS. (a)

By W. MacADAM ECCLES, M.S., F.R.C.S.,
Senior Assistant Surgeon, West London Hospital, and City of London Truss Society, &c.

Almost every instance of imperfect descent of the testis is associated with a hernia into the unclosed processus vaginalis. Almost all cases of hernia associated with an imperfectly descended testis should be submitted to operative treatment. It is thus that the value or not of the organ which has not passed into the scrotum becomes of great moment, and the method of dealing with it of the highest importance.

The function of a testis is primarily to produce spermatozoa for the object of reproduction of the species, but there is undoubtedly at least one other,

---

(a Abstract of Paper read before British Medical Association, 1902.

(a) Abstract of paper read before British Medical Association Meeting at Manchester, July-August, 1902.

although, perhaps, subsidiary use. Without either testis the individual will never acquire the full development of the male characteristics. Without the ability to produce spermatozoa on account of imperfect formation of the testis, the individual may still be capable of acquiring most, if not all, of the manly peculiarities, provided that he has the testes. Further, although possessing testes, yet the individual may not acquire the male characters, showing that these organs are lacking in both their proper functions. The testis, therefore, although it may not have reached its usual *habitat* in the scrotum, is yet in many cases of use to the possessor, in that it will enable him to develop certain peculiarities, which he would not otherwise acquire.

The value of the arrested organ in the case of unilateral arrest is not of course so great as it is in the instance of double arrest, for a single fully descended and fully developed testis is amply sufficient to perform all the requirements of full and complete growth of the body and the development of the male characters. Still even in these instances a value should or should not be set upon the imperfectly descended organ.

On the other hand when the arrest is bilateral the surgeon has to very carefully weigh whether or not the testis has a real value. An examination of a large series of arrested testes removed from adults show that by far the larger number have never been capable of forming spermatozoa. There are undoubted instances in which arrested testes have been the seat of spermatogenesis, but it will be observed that most of these have been cases in which the testes have never left the confines of the abdomen; in fact, it would seem that abdominal retention is not a bar to physiological testicular function. It is the inguinal testis which is debarred from producing spermatozoa. It would seem that delay in the inguinal canal in the muscular planes of the abdominal wall necessitates failure in the formation of cells capable of giving rise to spermatozoa.

It is an interesting fact that the testis of the boy before puberty, at least the testis that has fully descended, is entirely devoid, or nearly so, of a type of cell lying in the spaces between the seminiferous tubules. These interstitial cells are, however, beginning to be noticeable about the period of increased sexual development, and they may become very abundant.

In the microscopic examination however of the testis that has been retained, it is the rule rather than the exception to find these interstitial cells, and that long before the fifteenth year of life. Further, they are apt to be peculiarly abundant in those testes which have been removed from persons whose bodily growth is normal, in spite of the fact that their testes have never reached their normal habitat in the scrotum.

They may have the duty of producing a so-called internal secretion, a substance which is required for the right and proper growth of the body, and without its presence much of the normal growth may be lost, or the usual changes that should occur at puberty be profoundly modified.

That there is some obscure relationship between internal secretion of glands and the growth and division of cell-elements is becoming to be definitely recognised. Further, these internal secretions may also affect, and that very markedly, certain physiological functions of the body. For instance, it is well known that the removal of the testes or of the ovaries in adult life, and especially so if these organs are healthy at the time of their ablation, may be followed by severe, though possibly only temporary, nerve-storms in which the patient may be wholly irresponsible for his or her actions. On the other hand, supposing that the vasa deferentia only are divided, then there will still remain the testicular substance, and though this will atrophy, yet the glands will apparently retain their power of producing some form of internal secretion, which will obviate as a rule any nervous phenomena developing.

There are at least three ways in which the imperfectly descended testis may be dealt with when exposed in operating upon an accompanying hernia. First, to bring it into the scrotum and fix it there; secondly, to retain it within the abdominal wall; and thirdly, to remove it altogether. If the testis is of real value it should not be excised. It can be safely returned within the abdomen if it cannot be brought down.

The ideal method is that of orchidopexy, but unfortunately this is by no means always possible to carry out on account of the shortness of the vascular cord.

The plan of returning the testis within the abdomen has much to recommend it. By so dealing with the organ it is retained, and although it may not develop physiologically, yet its internal secretion will continue and be of service to the individual. Further, any tendency to hernia can be removed by the obliteration of the inguinal canal. Against the return of the organ within the abdominal walls is the argument that it is very prone to become the seat of malignant deposit, which in such a position would be highly dangerous.

There is, however, again a want of any definite evidence that an abdominal testis is so very subject to the onset of sarcoma or carcinoma. Seeing that instances of arrested testes are by no means uncommon, it is surprising to find how few records there are of malignant neoplasm of the imperfectly descended organ, and particularly so of the one that is within the abdomen. Another point against the return of the gland is that the possessor can no longer observe it, and may thereby become distressed, but this is overbalanced by his freedom from actual trouble in the organ itself.

To remove the organ has also much to recommend it. By this means what is considered by many to be a useless organ is ablated, all risk of malignant deposit removed, and all tendency to hernia obliterated by the suture of the canal. Further, such a removal would probably qualify the person to enter the public services, from which he would otherwise almost certainly be debarred by the medical regulations.

Against removal there are the arguments that the patient may regard the organ as one that it is well to possess, in spite of its being sexually useless, and that it may have some function of producing an internal secretion of benefit in the economy.

Taking, therefore, a case in which there is a unilateral arrest of a testis accompanied by a hernia on the same side, a radical operation is indicated, and the testis should be placed in the scrotum if this can be done perfectly easily and with a strong probability that it will not recede, but under other circumstances it should be preferably returned within the abdomen, unless there are special reasons why it is thought more advisable to remove it.

On the other hand, supposing that the case is one in which both testes are arrested, then it is injudicious to cut away either of them, for the amount of internal secretion that together they may produce may be sufficient to cause a proper development of the body in general, while that amount which one alone can provide may be altogether too little to cause this growth.

In such instances it is well to replace the testis within the abdomen on the side on which the hernia is, if it cannot readily be brought down, or there is no scrotum to receive it, for in this manner it is almost certain that its power of providing an internal secretion for the body is maintained, although there will be no attempt on its part to develop and produce spermatozoa, the possessor becoming virile but remaining sterile.

RODENT ULCER:

ITS PATHOLOGY AND TREATMENT. (a)

By J. D. McFEELY, F.R.C.S.,

Senior Surgeon Mercer's Hospital, Dublin; Member of Council, late Member of Court of Examiners, R.C.S.I.

In discussing the pathology of the subject I must state at the outset, in order to avoid any misconception, that I purpose confining my attention to what I may call clinical pathology—pathological phenomena observable during the progress of the disease—and so common an accompaniment as to merit more attention than, I fear, they have hitherto received. Some of these have not been noticed, as far as I am aware, at least in text-books; whilst many, if fully explained, might throw a new light on the *causa causans* of the disease. A Persian proverb says (*b*) : "Bonum est cribrare modicum sabuli, ut quis inveniat unam margaritam."

In teaching students at the bedside, I often try to impress upon them as forcibly as I can that in looking at any given case of disease they should try, not merely to look *at*, but by the light of pathology look *into*, the case ὡς εἰς τὸ κάτοπτρον (as into a mirror) if they would understand the changes that take place and apply rational and successful treatment.

If this be true with regard to disease in general, it is especially so with reference to diseases of which there is no consensus of opinion as to whether *any* treatment is effectual. "Tot homines, quot sententiæ" may be taken to be the general rule applicable to the treatment of rodent ulcers. If, however, this disease is to be treated on a scientific basis we must, I fear, still ask pathologists to tell us what rodent ulcer is?

Is rodent ulcer an epithelioma of the skin pure and simple? I shall leave it to others to answer this question, but will hazard the opinion that it is like the Scotch verdict—"not proven."

Now, as we are generally required to "give a reason for the faith that is in us," I shall briefly state the points from which I have drawn this conclusion.

(*a*) Rodent ulcer is essentially, as you are all aware, a local disease, and does not show metastases either by infecting contiguous lymphatic glands, or manifesting itself elsewhere beyond the seat of primary infection, as occurs in all other forms of the carcinomata.

(*b*) Even when left to follow its own free will—untreated, it shows a marked tendency at some part to take on a reparative process, whilst progressing slowly but steadily, in another direction.

(*c*) During its progress—this, I may remark, is the result of my own observations—it shows a marked tendency to avoid hair follicles, and will almost go out of its way, so to speak, to follow another course. Why this is so, if it be conceded, I can offer no opinion, unless perhaps it has a predilection for some particular tissue or cells.

I only know of one recorded case by, I think, Sir J. Paget, where rodent ulcer attacked the hairy scalp. The deeper layers of the cuticle are, as the disease progresses, attacked prior to the superficial or epithelial layer—as anyone will readily perceive in removing with a scoop or curette the diseased margins, the deeper being soft and friable—a contrast to lupus, for instance—whilst the outer layer seems unaffected, giving rise presumably to the terms "folded in" applied to these margins.

(*d*) The serous exudate, which is so common an accompaniment as to be looked upon as pathognomonic of the disease, seems to me to have a tendency to produce a form of auto-infection. This statement, unsupported by proof, will, I have no doubt, not commend itself to many here or elsewhere; nevertheless, I would ask you to look upon it as worthy of some consideration until such proof is at hand. This proof may, I hope, be furnished by inoculation with the exudate.

Observe, for instance, as occurs in the major part if not all of the cases where the disease is situated on the forehead or face, how the tendency is to extend downwards along the very course or channel this exudate follows. It is true there are exceptions to this rule; that this course is not always diseased, and often when so, undergoes a process of repair; but where the exudate is liable to accumulate, as towards the inner canthus of the eye, we almost invariably find a nidus of infection if the case is one of long standing; possibly from its liquefying or macerating action on the tissues.

Again, is it not possible that the unsatisfactory results of scraping or curetting are, in part at least, due to an auto-infection; the diseased portion infecting the raw surface?

What the cause of this exudate is, I am not quite prepared to say, but would suggest that the exciting cause is or contains the same "materies morbi" as causes the diseases, acting as an irritant on the vessels, plus the same cause as gives rise to exudates elsewhere, *e.g.*, into serous cavities, viz., altered state of vessel-wall, stases, want of external support, &c. Whatever be its cause, of one thing I am convinced, that the presence of this exudate is one of the best possible proofs that diseased tissue is still present.

(*e*) All surgeons will, I think, agree that caustics or irritants, *e.g.*, HNO_3 applied to truly carcinomatous growths, produce a very injurious effect by stimulating the cells to increased activity—mitosis—markedly exaggerates pain, whilst if the same be applied to rodent ulcer, the effect is in many cases to retard the growth. This one fact alone should justify one looking upon rodents as distinct from the carcinoma.

(*f*) I need only mention the marked difference in the rate of growth between truly malignant neoplasms and rodent ulcer.

Histologically, also, there are differences; but the time at my disposal will not permit me to say more than that these had better be left to the pathologist.

Until the pathology of the disease is placed beyond the question of doubt we might, while still looking upon the disease as closely allied to the genus carcinoma, more correctly consider it as intermediate between the truly malignant diseases on one hand, and simple or specific ulcer on the other.

I am almost inclined to regret that rodent ulcer is not a veritable child of the parent epithelioma; for then we might reasonably hope that this fell scourge, which has so long baffled our best efforts to find a remedy, might, in the not far distant future, be brought to submission, and cease to remain one of the opprobria of our profession, and the favourite hunting-ground of charlatans and quacks.

Treatment.

Before proceeding to mention in detail the particular form of treatment I adopt, let me ask, "Is rodent ulcer amenable to treatment without the probability of recurrence?" My answer to this question is "Yes," as much so as any simple or specific ulcer. This answer I give, not under the belief or impression that there are not other means of treatment which, if adopted with a firm belief in their beneficial properties might, and I am sure would, prove efficacious; but I submit the treatment I am about to mention has some claim to recognition. The results may, I hope, justify my conclusion.

I shall first briefly mention some of the recognised means that have been adopted with a fair amount of success. These may be divided into operative and non-operative.

Of the operative, the electro or thermo-cautery is I consider the best. Removing the diseased portion with the knife or curetting is, *per se*, by no means trustworthy or satisfactory; but on the other hand cautery, though giving good results, is not always applicable. Of the non-operative chlorate of potash, salicylic collodion or

---

(*a*) Paper read before the Surgical Section of the British Medical Association at Manchester, July and August, 1902.

(*b*) It is sometimes a good thing to "sift a handful of sand that one may find a pearl."

Zn. chloride is, I think, best. You are aware that of late the Finsen and X-rays are greatly in request, and may ultimately take their place as recognised adjuncts to others, but so much time and trouble are required, and so many exposures necessary, that I fear they can never, except in isolated instances, become practicable as routine treatment. Besides, they are beyond the reach of the general surgeon or practitioner, by whom only in many instances early treatment is possible—and, of course, early treatment must give the best results.

The treatment I adopt in case the ulcer is not very large, or easily accessible, is, in the first instance, pure formalin; if a second or third application seems necessary later, formalin glycerine 30 to 50 per cent., with or without tannin.

In case the patient objects to be anæsthetised, I first use a local anæsthetic, either cocaine, eucaine, or, better still, acöin; giving a hypodermic of morphia in five or ten minutes after using the application, if the pain is severe. After this the patient is generally asleep in fifteen or twenty minutes.

In cases where the disease is of long standing, and likely to engage the bones or be accompanied by extensive destruction of tissue, or, if not readily accessible, as in Nos. II. and III., I prefer to anæsthetise the patient and remove by knife or curette all available diseased tissue, and apply as a styptic either powdered tannin or suprarenal gland extract to stop oozing and facilitate the formation of eschar, and then use formalin or formalin glycerine, keeping the patient fully under the anæsthetic for about five minutes afterwards. When the formalin is applied it should not be allowed to evaporate. If pure formalin be used in the first instance I rarely find a second or third application necessary, unless to some isolated patches; but I should strongly recommend any person not to hesitate to use it as often as may be necessary to remove all diseased tissue. Herein consists the success of the treatment.

The dark, I might say black, slough which forms should be allowed to separate spontaneously, and may be assisted by some non-irritating ointment, &c. After, or very often before, this slough or eschar has separated, the granulations will soon sprout up, and, if healthy, grow vigorously. The rate of growth of the healthy margins is sometimes marvellous. In case No. 2 fully two square inches had completely covered in about fourteen days.

I shall now briefly give notes of cases treated by this method:—

CASE I.—M. G., male, æt. about 70. The ulcer was of five years' duration, during four of which he had been treated at regular intervals by an eminent City surgeon. I saw him for the first time in my study, in June 1900. The ulcer, the surface of which was about one square inch, extended from the centre of the forehead to the root of the nose and the inner canthus of the right eye along the fronto-nasal junction. He had been advised by several medical men to have it removed by the knife; to this, however, he would not assent. After rendering the part anæsthetic by a mixture of cocaine and eucaine, I applied a piece of gauze, just large enough to cover the ulcer, soaked in pure formalin, allowed it to remain for a few seconds, then covered over with a small portion of oiled silk, and applied a bandage. In about twenty minutes he was able to walk to his home—about a quarter of a mile distant. He informed me on his next visit that he spent the evening and a greater part of the night walking up and down his bedroom floor to try and keep the pain under control. I saw him afterwards at intervals of three or four days, and applied some simple ointment on each occasion. In about two weeks the eschar separated, and soon after I applied a second application as before, but to a portion only; and to one or two spots where the margin seemed indurated, a third and fourth application. After this, it was left to heal, a process that was completed about the second week of July (a period of six weeks). He attended to his duties as an attendant in a library during the entire time of treatment. In this case, however, I did not use the morphia.

My reason for trying formalin in this case was the hopeful results I had previously obtained in another case of inoperable carcinoma of the neck. Previous to this I had not heard of its being used, successfully or otherwise, in cases of rodent ulcer.

CASE II.—Mrs. B., æt. 65, was sent up to me from the country by Dr. McQuaid, of Co. Cavan. She was admitted into Mercer's Hospital, July, 1901. The ulcer, of over fifteen years' duration, was situated on the forehead, and extended from ¼ in. from the margin of the hair to the root of the nose—about 2 ins. by 1⅓ ins. From the lower margin of the ulcer a diseased track or channel, about ⅛ in. wide, extended along the root and side of the nose to the inner canthus of the left eye, engaging a small portion of the upper eyelid behind the ciliary margin. An isolated patch was situated on the nose near its base. She declined positively to be put under an anæsthetic. I applied the same treatment as above on two or three occasions, substituting formalin-glycerine with tannin on the second and third occasion, to minimise the pain. There was a good deal of headache, some occasional rises of temperature, and œdema of the eyelids after each application. About the end of the second week a considerable portion of the frontal bone came away with the eschar, leaving the meninges clearly pulsating. I then strongly urged her to allow me to examine the diseased bone under an anæsthetic, but she persistently refused. She left hospital in August, the entire wound having completely covered over, but a small portion of indurated tissue remained over the eyelid, and along the side of the nose. She had promised to return, should the disease recur, which she did on May 28th of the present year.

I was agreeably surprised to find the wound on the forehead still healed with no sign of recurrence of the disease, except a small patch at the margin of the eyelid, where I had expected. But beneath the scar tissue covering the cavity left by the removal of diseased bone could be felt and seen a small puffy, fluctuating swelling, and the edge of the bone projecting and giving the feeling as if another portion of it had become semi-detached. This time I was able to persuade her to allow herself to be anæsthetised, otherwise, she was informed, no further treatment would be undertaken. Accordingly, on the following day, under anæsthesia, I laid open the scar for about three inches, exposed the bone, and opened the dura mater and evacuated about one ounce of clear fluid, resembling the exudate previously referred to. The bone was then scraped where it appeared unhealthy, the edges nipped off by a bone forceps, pure formalin was applied to the bone and the incised edge of the dura mater, the wound dressed and allowed to heal by granulation; this took some time, as it was three quarters of an inch deep and two inches in diameter either way. She left hospital on July 15th perfectly healed, but with a slight depression at seat of scar.

CASE III.—This patient presented himself at the out-patient department of Mercer's Hospital, in May of this year, a pitiable sight; he had sought admission elsewhere, but was told nothing could be done for him.

He gave the following history:—About five years since noticed a small pimple on the side of his nose, which itched and annoyed him occasionally, causing him to pick it with his finger nails; it continued to spread. He was treated first at a dispensary in Limerick for six months, next at St. John's Hospital, and as an extern of the same (Limerick) for about a similar period. He states he was treated by nitric acid in the first instance, but subsequently was treated for lupus and scraped. Later he found his way to Dublin, and was treated at Richmond Hospital, where he was "scraped"; returned again to Limerick, was again treated as an out-patient at St. John's Hospital, and continued so till he returned in May to Dublin.

As the appearance to the naked eye closely resembled lupus I decided before beginning treatment to have a section examined histologically; this Professor McWeeny was good enough to do, and pronounced it a typical case of rodent ulcer. You will observe that the greater part of the upper lip, the cartilages of the nose and soft parts covering them, had disappeared, except a flap on the left side, the bony framework of the nose was extensively engaged, the disease appearing to have extended to the posterior nares and upper part of pharynx. I told him that his case seemed well-nigh hopeless, but if he was able and willing to suffer pain, and left himself unreservedly in my hands, I would try what could be done. This he accordingly did.

Like the other patients, he would not consent to be anæsthetised, so I used a spray, containing equal parts of formalin and glycerine and tannin, to the nasal cavities; pure formalin to lip and edges of wound, having previously applied a solution of acöin. The pain seemed intense; I gave him a hypodermic of morphia a few minutes after; he was soon free from pain and asleep. A few days afterwards he was told a further application was necessary. He then consented to be put "asleep." He was removed to the theatre, anæsthetised with ether, the diseased portions, including the bones—as far as could be reached—thoroughly scraped, the indurated (folded) edges trimmed with a knife. A solution of supra-renal gland extract applied to stop oozing, then pure formalin applied as beforementioned. The inhaler was again applied for a few minutes, so as to keep up insensibility to pain; he was then dressed and returned to bed. This patient is still under treatment, but all diseased tissue has been removed and healing is quite satisfactory. During this man's convalescence a patient in an adjoining bed with whom he had some difference remarked one day, "You will never show your nose in Limerick again."

As this was the first time I had used formalin with an anæsthetic, I must confess I had some serious misgivings and fears as to the result, formalin being so volatile and ether no less so, and both coming in contact, nor had I previous knowledge or experience to guide me, but the results were all I could desire; by the time he had recovered from the effects of the anæsthetic there seemed to be no pain, this was borne out in the second case mentioned above. That patient, although 65 years old and very feeble and infirm, showed not the slightest unpleasant or dangerous symptom. The second patient was under ether three-quarters of an hour. In future I shall always give an anæsthetic where possible.

It may be asked what special action has formalin in such cases. My opinion is that the nucleus of the cell with which it comes in contact is destroyed—disintegrated, if you will—and so mitoses stopped; hence proliferation of these cells ceases. That it has some such effect even on truly malignant growths I have very little doubt, without in the least degree interfering with or impairing normal cells, but rather assisting the formation of scar tissue.

To summarise briefly, I have tried and seen almost all other methods of treatment that have been adopted, but do not consider that any other recognised method will give as good results.

The scar tissue that forms is smooth, does not contract, and soon comes so closely to resemble normal tissue as to be almost unrecognisable.

Formalin is practically non-toxic; this I have proved, at least to my own satisfaction, by injecting 25 minims of pure formalin into a large inoperable carcinoma of the neck, without producing the least injurious effects.

The time required for treatment varies, of course, with the extent of the disease, but may be put down as from one to two months, when the wound is allowed to heal by granulation; much less time might be required if a plastic operation were done.

The extreme pain which in the first case I found to be a very serious obstacle, can be readily overcome by anæsthetising the patient.

I have gone to some length in advancing reasons from a clinical point of view which occurred to me why rodents can hardly be considered truly malignant growths. If this view be still unaccepted, then may I be allowed to hope, nay to assert, we are at the dawn of a new epoch in the treatment of malignant disease.

It may be argued, three cases can prove nothing. My answer to that is—give me sufficient time and material, and I shall produce thirty-three, yea, or three hundred and thirty-three equally good results.

How formalin stops cell proliferation in diseased tissue or malignant growths, without destroying the vitality of normal cells, may seem incomprehensible, that it does so, I am fully convinced. But how? The answer is easy, if we admit a parasitic origin; without it, difficult.

Already I have trespassed too long on your valuable time and patience, and will now conclude with the hope that whatever you may think of the merits or demerits of the treatment brought under your consideration I claim no more than a humble and earnest effort, as the result of long thought and some anxious consideration, to do one man's part to contribute a quota to the relief of suffering humanity.

> "Still climbing after knowledge infinite,
> And always moving as the restless stars
> Until we reach the ripest fruit of all."

Since writing the above the author desires to add that he has had some most satisfactory results in the treatment of malignant growths. A further communication on the subject will appear soon.

Clinical Records.

A CASE OF ACUTE HYDRAMNIOS—PLACENTA PRÆVIA LATERALIS—TWINS FIVE AND A HALF MONTHS—MACERATED.

By Arthur N. Holmes, M.B., B.Ch., B.A.O.Univ. Dub., L.M.,

Extern Assistant, Rotunda Hospital, Dublin.

On June 2nd I was sent for to see a patient in the Extern Department of the Rotunda Hospital who was stated to be bleeding.

On arrival I found her somewhat blanched and weak, with a pulse of 140 and temperature of 101°.

On inquiry I found she had been bleeding on and off for a month past, and that on May 30th she had bled very considerably. The uterus, on palpation, I found the size of full term: tense, no fœtal parts to be made out or fœtal heart heard. Fluctuation wave easily elicited. Patient was having no pains and did not complain of tenderness during examination except for a handsbreadth above the symphysis pubis.

She stated, in answer to my question, that she was only five and a-half months pregnant, and up to three and a half days previously had been the normal size for that time, but that during the last three and a-half days she had grown with great rapidity. So much so, that she found considerable difficulty in respiration. How sudden the onset of the distension was, she pointed out, by the fact that, having gone to bed feeling comfortable she woke the next morning feeling very distended, and found she could not get her clothes to meet round her. After that she suffered from severe pains in the abdomen, increasing difficulty in respiration. and hæmorrhage, which eventually caused her to send to the hospital.

On vaginal examination, the anterior fornix was found very boggy. The external os barely admitted two fingers. A bag of membranes was felt, unruptured, and the hand, and cord, not pulsating, of a very small child found presenting. The membranes were quite flaccid. No placenta could be felt. As the hæmorrhage was continuous, though at the same time slight, chloroform was administered—which the patient took very badly owing to the dorsal-position exaggerating the difficulty of respiration—and the vagina plugged with sterile cotton-wool, and a T-shaped bandage and binder applied. The student in attendance was given directions to send to the hospital for me as soon as the patient began to get pains.

By this time I had made up my mind that the case was one of acute hydramnios—probably of twins, as the presenting sac showed no distension, and there was a previous history of twins on August 2nd, 1901—and possibly of placenta prævia. Concealed accidental hæmorrhage was, to my mind, excluded by the facts already stated, viz.:—

1. Absence of tenderness on palpation.
2. By the fact that if we believed the patient's statement that she was only five and a half months pregnant, it was inconceivable that she could have lost

sufficient blood to distend a five and a-half months' uterus to full term, and yet not be in a state of collapse.

3. The feeling the hand of the fœtus verified the patient's statement as to the duration of pregnancy.

At three o'clock, p.m., three hours after I had plugged the vagina, I received a message that pains had started. I went back at once and removed the plugs. The external os then admitted four fingers. The edge of the placenta was felt lying just above the internal os and on the anterior surface of the uterus. I then punctured the presenting bag of membrane, and little or no liquor amnii escaped. An arm prolapsed and was seized with ovum forceps. By sweeping the fingers along the back of the child a leg was caught and brought down, the arm then pushed up, and the child extracted without difficulty. It had been dead for about five days, and was about five and a-half months old. A second bag of membranes was then felt protruding through the os, very tense. I punctured as high as possible. and about ten pints of liquor amnii—very like ovarian fluid in colour—allowed to escape slowly, the fundus being carefully followed down. The second child was found presenting by the back: a foot was seized and brought down, and the child extracted. It was, like the first, dead, but had evidently died at a more recent date—probably two days before. The uterus contracted fairly well, but at the end of ten minutes smart hæmorrhage began, and, expression failing, a hand was introduced into uterus, and placenta, which was very adherent to the anterior wall, removed. In doing so a septum about an inch long was felt at the fundus. Uterus was curetted and douched, and contracted well. Temperature, 100·2°, and pulse 100 on leaving. In twenty-four hours the temperature was normal and pulse 99. After that, pulse fell to normal, and patient, after an uneventful puerperium, was discharged well on the tenth day.

The case is one of considerable interest on account of the great rapidity of the distension, and as the woman's history was spontaneous and very definite, I do not see any reason for doubting her. It is of interest also to note that McClintock's observation as to the polyhydramnion usually occurring in the second sac was borne out in this instance. Again, both children were males, and the same authority states that he found excess of liquor amnii more frequently with females than with males in the proportion of twenty-five to eight.

The placenta—a common one—did not show any pathological change, and there was no malformation of either fœtus.

It is by Dr. R. D. Purefoy's kind permission that I am enabled to publish the history of this case.

France.

PARIS, August 31st, 1902

ANTI-STAPHYLOCOCCIC SERUM.

AT the meeting of the Académie de Médecine Professor Doyen presented a new serum which, in doses of one or two drachms, acts against staphylococcic infection with such intensity that in two or three hours after the injection the pain caused by the inflammation has disappeared. The results vary, however, according to the method of injecting and the stage and extent of the central necrosis.

In boils and anthrax the injection made into the muscles of the hip or near the seat of the affection, if made before the formation of the core, determines the rapid cessation of pain, arrest of the inflammatory tumefaction, and a cure by resolution in twenty-four or forty-eight hours. If the core has been already formed, the extension of the inflammation is arrested and the gangrened tissue is eliminated in two or three days without pain through a small orifice of the epiderm.

In case of large carbuncles having the aspect of a diffused phlegmon, the speaker said that an injection of two drachms of the serum allayed the gravest symptoms in less than twelve hours. The suppuration diminishes, the necrosed parts are eliminated through small cutaneous orifices, and the walls of the abscess granulate so quickly that at the end of four or five days the wound is reduced to a simple loss of substance of the epiderm; large anthrax gets well without incision or cauterisations, under a simple antiseptic and emollient dressing.

But this is not all the advantage claimed by Dr. Doyen for his serum. A case of puerperal infection yielded in twenty-four hours, in spite of the grave general condition of the patient, and which would have taken eight or ten days of antiseptic intra-uterine injections to cure.

Perhaps the most remarkable case was that of phlebitis of the ophthalmic vein and the cavernous sinus complicated with the usual symptoms: double exophthalmia, total amaurosis on the left and partial on the right side, high fever and delirium. All the left side of the nose was transformed into an enormous phlegmon, and the suppuration had invaded the left orbit.

One injection of two drachms brought down the temperature and arrested in one night the evolution of intracranial accidents. The patient recovered, with complete amaurosis of the left eye and slight decrease of the vision in the right. This anti-staphylococcic serum acts on staphylococcic infection with the same rapidity as the serum of diphtheria on that malady. Its indications extend considerably beyond the treatment of carbuncle and anthrax. Tonsillitis due to staphylococci, bronchopneumonia where the same infection frequently predominates, osteomylitis and all infections in general where that microbe either exists alone or predominates, are modified with advantage by the same treatment.

Of the 200 injections which had been practised by Dr Doyen not one was followed by an abscess. In about 10 per cent. of the cases a slight general reaction was produced, and sometimes œdema of the face and ears, when the injection was made in the back of the neck for anthrax or carbuncle of that region. The point of election, however, was the lumbar region, and more especially the gluteal muscle.

In concluding his remarks, Mr. Doyen said that the serum acted as a specific on the staphylococcus, and from the cases above enumerated, and very many others which he had noted, it constituted in his mind an extremely important conquest for medical science, and for serotherapy in particular. The new serum permitted them to hope that a real progress was being made on the road of immunisation of infections which remained hitherto refractory to serotherapy.

ONE of the contributions to the v. Leyden Celebration was a paper by Prof. Renvers on

THE TREATMENT OF THE DISEASES OF OLD AGE.

The most important changes of advancing age affect the circulatory apparatus, as well the vessels as the heart, and not infrequently the whole system is affected by an arterio-sclerotic process. Naturally the other organs and tissues also undergo the changes of old age. The most important of all pathogenetic signs is the failure of powerful reaction against external and internal damage. When all the other signs of fever are present there is no marked rise of temperature. With increasing age infective diseases give place to the diseases of tissue change that run a chronic course. The reason further lies in acquired immunity due to the cells overladen with products of tissue change affording an unfavourable soil. If infection occurs, as for example pneumonia, this runs in old age quite a different course from that in a young man. The rise of temperature is but slight, the sputum rarely characteristic, the expectoration slight, the slight acceleration of respiration frequently the only objective sign of some disease of the respiratory tract. The changes in the central nervous apparatus due to the intoxication are to the front (mild delirium, &c.). In old age almost all kinds of pathogenic bacteria may set up pneumonia. But the diplococcus decides the course rather than the form. In infective diseases in the old the excretion of noxæ through the kidneys, intestines and skin is arrested. A condition of chronic poisoning arises that manifests itself in increasing weakness, especially of the circulation.

In the matter of treatment, above all things the circulation must be excited. The equivalent of this is absolute rest; that position is the best that is the most agreeable. Further, warmed pure air must be provided, cooling of the body must be prevented by warm clothing, and the temperature of the room should be at least 68° F. Centripetal rubbings, friction with hot dry cloths, raising of the extremities influences the various stasis, hot foot and hand baths with mustard, hot partial washing of the skin, moist partial packings are an important support. Warm baths in old age are less suitable on account of the bodily exertion necessary for them, cold also on account of the extraction of heat. Mild massage is very stimulating to the circulation. Care should be taken of the bowels, and warm applications are useful in the stimulation of the abdominal circulation. Too free feeding should be avoided as it burdens the heart and vessels. Medicaments are best given subcutaneously; the caffein salt or camphor oil are the best, with, if necessary, the addition of ether. Digitalis, as a rule, is not well borne. Frequently, however, the end is attained by giving strong coffee or tea, with the addition of brandy or alcoholic drinks. Food must be given often and little at a time, more fluid or pultaceous than solid, more hydrocarbons and fats than much albumen. The old man lives through the administration of the daily caloria, and one day without food brings about a loss of power that may never be made good again. The mouth and pharynx should be cleansed with borax and glycerine as aphthæ are apt to develop. The food should be given warm and the solid parts minced. Spices and salt should be given freely; alcohol also on account of its stimulating action. Food is best given in the shape of well cooked meats, sugar, milk and cream. The required amount of albumen, 60 to 80 grms. is best given as an addition to the milk in the shape of somatose or plasmon. If necessary, food should be given by the rectum.

At the Society for Innere Medizin Hr. Albu showed two

Rare Preparations.

One was a benign gastric tumour after simple ulcer. It was a mucous membrane tumour, almost homogeneous, showing only a few inflammatory products embedded in between. It was therefore a simple adenoma. He had treated the patient five years before for gastric ulcer, and she had been discharged cured. After four years of good health, the symptoms returned a year ago with renewed difficulties. Rapid emaciation, dyspeptic symptoms, and vomiting.

Examination showed marked impairment of movement, free hydrochloric acid, and a tumour the size of an apple above the umbilicus. On September 2nd last year the tumour was resected. The patient had improved a good deal since the operation, and the symptoms had disappeared. 2. A countryman who up to a fortnight before had been strong and healthy, came to the polyclinic with cyanosis of the lips, nose, and extremities. Examination revealed myocarditis. There were also stenosing symptoms of the œsophagus, repeated free vomiting of blood, which the speaker thought to be due to rupture of varices in the œsophagus. On admission into hospital the symptoms improved. In delirium he escaped from hospital, but was brought back. The stenosis was now worse, but a sound in the œsophagus encountered no obstacle. After some days violent coughing came on, and after this vomiting, occurrences that seemed to point to a communication between the trachea and the œsophagus. The man then died quickly from asphyxial pneumonia. The autopsy showed grave myocarditis, a diffuse scirrhous carcinoma in the œsophagus, and further, just above the cardia, a small uncommonly flat ulcer, which proved to be carcinomatous. The speaker thought that in passing the sound, which was done with the utmost care, however, a small abrasion had been caused, into which particles of cancer matter had been carried. The condition was one of great rarity.

Vienna, August 30th, 1902.

Three Obscure Cases.

At the "Verein Deutscher Aerzte," Altschul related the history of three very obscure cases.

The first was that of a female, æt. 17, strong and healthy, of a robust family. In her youth, however, she appeared to have suffered from a sort of "petit mal" attacks which gradually ceased to recur. In her fifteenth year she had what her parents called a "gland" fever, but since then, with the exception of a sore throat, she had been in good health.

When first seen her throat was slightly red and there was slight fever, but there was nothing to attract attention. After a time the fever increased and the glands in the throat and neck became larger, especially in the supraclavicular region. Aspirin and salophen in 0 25 gramme doses were given twice a day. A few days later she developed exanthematous urticaria involving the lower extremities, but there was no itching, this fact being more suggestive of a medicinal rash. These symptoms persisted, notwithstanding the treatment.

The temperature rose further to 38·6° C. (101.5° F.) the following morning; in the evening 39·6° C. (103·3° F.), and the pulse 80. By this time the symptoms pointed to typhoid fever, as the tongue was dry and coated, but no roseolar symptom was present to confirm the diagnosis, neither was there enlargement of the spleen, nor diarrhœa. The urine was healthy in colour, and about a litre was passed in the twenty-four hours. Widal's serum test was applied, but the result was negative.

On the mucous membrane of the throat a few streptococci were discovered. The fever continued for five weeks and then began to subside; in another week she appeared to be convalescent, and she ultimately recovered perfectly without the nature of the disease having been discovered.

The second patient was also a female, æt. 16, who had always been healthy. She was taken suddenly ill after bathing in the river Moldeno, with persistent vomiting and slight fever. The vomiting continued for eight days, with some fever, when it gradually ceased and convalescence set in slowly. A few weeks later, however, the hair to began to fall out rapidly in alarming quantities.

Various diagnoses may be suggested in this case; it may have been typhoid fever, gastro-enteritis, polluted water intoxication, gastritis mycotica, or simply chemical intoxication from the river water. In Prague during the bathing season these cases are not uncommon. The data are insufficient to adopt the *post hoc ergo propter hoc* view, and because it occurred after bathing it need not necessarily have been the water.

The third case was one of "febris ephemera," occurring in a perfectly healthy female, æt. 26. She was taken suddenly ill one evening, with severe shivering and great pain in the head. The latter yielded to an antipyretic, and next morning she was perfectly well. The cause of these fevers, he observed, was very enigmatical, and it was questionable whether the antipyretic acted as an antidote to the poison, which did not agree with experiments in animals.

Epstein, in criticising the cases, said his opinion was that the first case was one of erythema nodosum, which in young persons very frequently resembled typhoid fever. The long continued fever might be partially of a hysterical nature, a possibility which must never be lost sight of in such cases.

Nachod said that such cases often occurred in children, in whom the fever was continued for a very long time in strumous conditions where suppuration and degenerative cheesy changes were taking place in the glands in the region of the mediastinum or in the bronchi. When it occurred in the thyroid or superficial glands the cause can be demonstrated, but when deep the disturbing cause was not so perceptible.

Pick agreed with Epstein in diagnosing the first case as one of erythema nodosum. He was also at variance with Altschul in looking upon Widal's reaction as an element of diagnosis in typhoid fever, as he considered it of no value whatever in differential diagnosis. The two reactions that were of any value in this disease were the Diazo reaction and the enumeration of the leucocytes in the blood. The use of antipyretics in fever was a return to former doctrines which taught us to keep the temperature down by force and low diet, but the latter should not be long practised or the patient might be brought too low. In opposition to this method of treatment Curschmann advocated "feeding"—"good feeding"—as the proper treatment of typhoid fever.

Altschul, in reply, said he could not accept the theory of the first case being one of erythema nodosum, as no external exanthem or nodules were at any time observed. The suggestion of a "cryptogenetic septicæmia" in which such exanthemata are suppressed is a very enigmatical diagnosis to entertain. As to the suggestion of tuberculosis of the lymphatic glands that might be dismissed as the history, speedy recovery and present healthy condition disproved it.

NEUROTIC DISTURBANCE IN A MANGANESE WORKER.

Jaksch presented three patients who were engaged in the manufacture of permanganates all suffering from nervous symptoms, such as paresis, paræsthesiæ, exaggerated reflexes, ataxia, and defects of speech. No trace of manganese could be found in the urine.

Although grave suspicions attached to the trade he was not inclined to accept the toxic effect of the metal as the cause. He thought the cause would more likely be discovered in the conditions or nature of the work, such as the exposure to heat during the period of employment, as for instance the plates which are handled have a temperature of 120° Cent. (or 248° Fahr.) which are held at a distance from the head and keep that organ at a temperature not more than 4° less than that of the metal itself, which he thought was enough to account for the nervous troubles. Another reason for entertaining this opinion was that among the large number of hands employed very few were thus affected.

In connection with this case he recorded his experience of a man engaged in working cyanide of mercury, who finally died from uræmic poisoning. Before the uræmic symptoms appeared he had examined the blood from time to time and found 0·04 of a gramme of uric acid, and at a later period 0·6 gramme, or 9·2 grains per cent. These results confirmed the long established opinion that the symptoms of toxic uræmia were in proportion to the uric acid in the blood.

MULTIPLE UNILATERAL CEREBRAL AND CERVICAL PARALYSIS.

Walko showed a patient with multiple paralysis of both cervical and cerebral nerves, which he diagnosed to be due to a tumour in the cerebellar fossa.

Czernaak was inclined to question the diagnosis in this case on account of its long duration, *e.g.*, thirty-two years. He thought the more probable cause of the multiple paralysis was due to an aneurysm.

Piffl observed, after examining the patient, that he had suffered from a fœtid discharge from the left ear, which on careful examination was closed up with a bluish red swelling, this being an indication of the presence of a cerebral tumour.

Continental Notes.

[FROM OUR SPECIAL CORRESPONDENT.]

CONTINENTAL CRUSADES AGAINST ALCOHOL AND CORSETS.

Two Continental "crusades" seem to have come to stay. First, in France, the anti-alcohol agitation, favoured as it is by an increasingly large proportion of leading intellectual spirits of the day, including many able young men, medical, clerical and literary. To those old enough to recollect the earliest temperance associations in England, the present French movement appears to have much resemblance to that so-called "moderation" movement which preceded those more thorough-going total abstinence societies, unintentionally nicknamed by one of their stalwart but stuttering advocates, "t-t-tee-total."

The second crusade is of Germanic origin, and is against the wearing of *Corsets!* Previously we have heard rumours of a somewhat similar aristocratic advocacy of dress-reform in Vienna, but it was apparently too rational a reform to take root permanently in the frivolous fashionable Austrian metropolis. The present German idea, on the contrary, is taking hold of the well-to-do and substantial middle classes of Westphalia, Saxony, and Rheinland. Seated in the restaurant of the cosy Savoy Hotel, in the Central Railway Square of Frankfort, we could not but overhear this anti-corset controversy loudly and warmly argued pro and con by several professors and others, who finally adjourned to the Palm-Gardens of Frankfort to see the anti-corset garb in actual wear. Having become interested in the discussion we also went to these gardens, accompanied by an Alsatian physician, enthusiastic for the new "costumes hygieniques."

On arriving at the handsome Palm-Gardens, crowded as usual on the Sunday evening, we witnessed various illustrations of the new costumes, ample corsages, short robes, boleros, &c., &c., worn without rigidity and seldom well-fitting, but evidently cut and made to be so worn, quite independently of all Parisian fashions—young maidens and comely matrons, dressed in colours and materials of all kinds, and without whalebones or flowing skirts.

The good doctor joyously pointed these out to us; saying, "Our German physiologists have declared *une guerre à outrance* against the corset principally and to the long dresses trailing on the ground, as detrimental to the health and hygiene of woman. We have made, now over a year, an ardent campaign on behalf of a costume more conformable to the free movement and the normal development of these delicate beings who delight in toilettes. We write articles daily on the subject, interview and interest physicians, scientists, artists, authors; and, above all, we hold conferences, often numerously attended. And," he confidently added, "we shall triumph, for already many of our most influential and elegant country-women are braving the ridicule following first attempts, and are demonstrating practically, as you now see for yourself, the good sense and the salubrity of a costume which gives both at home and on the promenades, liberty of movement without oppression, and a faculty of free breathing so essential to health. We will free Germany of *jolies poupées* deformed by coquetry and literally dying of compression. You have only to see the body of a woman on an anatomical table to comprehend at once the crimes committed by modern toilettes, which compress and deform the trunk to the great detriment of all primordial organs."

INCREASE OF WOMEN MEDICAL STUDENTS.

Yet a third interesting change on the Continent (we cannot call it a "crusade" but possibly a *conquest*) is the notably increasing percentage of female students in the *medical* schools of the Swiss universities. The following figures seem to portend a "turning of the tables" in the next generation. It may be mentioned that in some cities the number of female medical students has already overpassed the number of male medical students, as at Berne, where there are now 190 female medical students against 174 male students; Geneva, more conservative, has 183 male to 163 female students. The total number of women students of medicine at all the Swiss universities is 511.

The Operating Theatres.

WEST LONDON HOSPITAL.

Nephrectomy for Suppurating Kidney. — Mr. **Swinford Edwards** performed the above operation for a man, æt. about 38, who had suffered from stricture of the urethra since he was a boy. At the age of seven he sustained an injury to the urethra, which soon resulted in stricture, for which lesion he had undergone internal urethrotomy on four separate occasions. External urethrotomy had also been done. The patient had always found it difficult to maintain the patency of the passage by means of the bougie, owing to an excessive sensitiveness of the urethra. Some four months previously he had been admitted into St. Peter's Hospital under Mr. Edwards, in a very critical condition, with a large and tender swelling in the right lumbar region, which was evidently renal. There was considerable fever, and the urine was scanty, with a copious deposit of pus. Nephrotomy was at once performed, and three separate abscesses opened and drained. The condition of the patient was then such that Mr. Edwards considered that the removal of the organ would prove fatal. The patient was much benefited by the operation, and left the hospital with a couple of discharging sinuses about a month afterwards. Ten days ago he was admitted into this hospital with the object of removing the kidney, if possible, as the renal abscess was still discharging through a sinus in the loin. Micturition was difficult, and the stream very small. The urine was loaded with pus and very foul. The patient was almost bedridden, looked very ill, and had a temperature ranging from 99° to 101°, and a rapid pulse. Evidently the first thing to be done was to provide a free outlet from the bladder. So Mr. Edwards again performed an internal urethrotomy, afterwards passing Lister's sounds. The bladder was well washed out with 1 in 10,000 sublimate solution. The patient stood the operation well and was much benefited by it, and Mr. Edwards thought the time had arrived for the removal of the suppurating kidney. The patient having been anæsthetised, prior to turning him on his side a series of steel sounds was passed to ensure a free urethra. The usual lumbar incision was made and the sinus dissected out. A considerable amount of dense fibrous tissue had to be cut through before the kidney could be exposed. It was then found a matter of some difficulty to free the kidney, or what remained of it, from the strong adhesions all around. The pedicle was transfixed and tied in two parts. After having separated and tied the ureter a few bleeding points had to be secured in the stump, but really, considering the extent of the operation, but little blood was lost. During the operation, and especially when the kidney was dragged upon the patient showed signs of collapse, but rallied again after the subcutaneous injection of strychnine and a brandy enema. The operation was completed by the insertion of a large rubber drain and the application of the usual gauze dressings. Death ensued about three-quarters of an hour after his removal to the ward, during the process of transfusion. Mr. Edwards remarked that it was to be regretted that the patient had not sought relief sooner than he did on the occasion of his admittance into St. Peter's for renal suppuration, when a nephrectomy might possibly have been performed with a better result.

Registered for Transmission Abroad.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 3, 1902.

LUNACY IN 1901.

The annual Report of the Commissioners in Lunacy is a document of interest and importance to the medical as well as the lay community. It registers the facts of mental disease in a way that enables the observer to compare practical results with theoretical opinions. There can be no doubt that the scientific study of lunacy is leading up to conclusions that will be of the utmost value to mankind, inasmuch as it tends every day to clear up the doubts that have so long surrounded this special branch of professional work. A specific instance of that kind of advance is afforded in the bold speculation that some forms of mental aberration are due to septic disturbances of the brain matter. Here, again, we are brought face to face with the ubiquitous microbe, which is the parent of such multifarious and far-reaching toxic irritations in the human body. What would have been thought of a man who a short generation ago ventured to prophesy that madness might in some instances be due to the invasion of the body by micro-organisms? To-day, however, that proposition appears to be supported by a reasonable amount of evidence. It need hardly be said that anything which tends to reduce the amount of lunacy will be of unspeakable value to mankind. Of late years there is little doubt that lunacy has been on the increase. That fact is supported by the figures in the present blue-book, which is the fifty-sixth that has been issued by the Commissioners. The total number of notified lunatics in England and Wales on January 1st, 1902, was 110,713, being 2,769 more than on the corresponding date in 1901. This increase compares with an increase of 1,333 in 1900, one of 1,525 in 1899, and one of 3,114 in 1898. The average annual increase in the ten years ended December 31st, 1901, was 2,286, and in the five years ended the same day, 2,270. The increase in 1901, therefore, exceeds the average annual increase in the preceding ten years by 483, and that in the preceding ten years by 500. It is interesting to note that there is an increase in the proportion of private as against pauper patients, a fact which the Commissioners attribute mainly to the increased provision made in asylums for the better class of patients for whom moderate rates of payment can be afforded. The main results of modern lunacy treatment may be broadly taken from the statement that no sustained advance has taken place in the recovery rate during the past thirty years, but there has been an important diminution in the death-rate. The Commissioners cannot attribute this lessened mortality to any single agency, but there can be no doubt, they think, that the main causes are improved sanitary conditions in asylums, better nursing of the sick and infirm, and the more earnest endeavours in recent years to render the lives of the insane under detention more happy. As to the influence of occupation, we find for the five years from 1896 to 1900 inclusive that the yearly average of clergymen of the Established Church was 30; medical men, 30; barristers, 6; solicitors, 19; civil servants, 49; artists, 18; teachers, 35; authors and editors, 23; musicians, 26; actors, 14; soldiers, 263; bankers and bank clerks, 321; commercial travellers, 178; agricultural labourers, 480; butchers, meat salesmen and grocers, 237; and other handicraftsmen, 515. It is a most interesting sign of the times to note of Broadmoor Criminal Asylum that in that colony of troublesome and dangerous patients there has been no employment of mechanical restraint throughout the year. Altogether, this Report registers an important stage in the practical treatment of lunacy.

DIAGNOSIS AND PROGNOSIS.

Thanks to the progress which sciences germane to medicine have made during the last half century, diagnosis has become far more exact than was possible when so little was known with regard to the correlation of groups of symptoms and pathological changes. We owe this advance in great part to the encroachment of the surgeon on fields previously regarded as exclusively medical, his ante-mortem examinations having thrown a flood of light on associations which were previously merely suspected

The greater perfection of the instruments which enable us to obtain precise knowledge in regard to organs and tissues which are hidden from sight and are with difficulty accessible to ordinary methods of exploration has also conferred upon diagnosis the precision which is indispensable to accuracy of deduction. In the matter of diagnosis the physician is on tolerably sure ground, and although, since the personal equation can never be ignored, mistakes are still possible, they are for the most part attributable to want of care or inability to appreciate the significance of data. So far, the physician is on fairly solid ground, but it is quite otherwise when he ventures to forecast even the near future. Here he is reasoning from the known to the unknown, and, metaphorically speaking, he has only one foot on the ground. The most experienced physician, when he formulates a prognosis in a given case, can but enunciate the doctrine of averages, and in virtue of that doctrine he is doomed in a certain proportion of cases to fall into error. Yet after the initial question which every patient addresses to his medical adviser, "What is the matter with me?" he is almost sure to ask, "What is going to happen?" and the question is one which it behoves the practitioner to answer with the greatest prudence. No physician is long in practice before he discovers that, as Voltaire once observed, nothing happens but the unexpected; the most trivial affections, in apparently robust patients, end disastrously, while others, obviously more severe, recover. The old physician who said he never acknowledged that a patient was dying until he was dead, was at any rate on the safe side, and much might be urged in favour of this attitude, which is in every way preferable to that of the pessimistic physician who ruthlessly declares the case to be hopeless from the onset. Such an attitude, even if justified by events, has the incontrovertible drawback of depressing the patient and of discouraging those in attendance upon him. The physician ought to be a man of sanguine temperament, but he should not allow free play to this temperament in the matter of prognosis. Bearing in mind the large number of factors which must necessarily escape his observation, he will take care to temper the optimistic character of his utterances to the patient by more guarded remarks to the friends. Symptoms and signs tell what is, not what will be, and the physician must cultivate the faculty of never being surprised at anything, but of quietly expecting everything. Room must always be left for the chapter of accidents, and in medicine death is the accident. To foretell the duration of a labour is like foretelling the arrival of a ship in port without knowing at what speed it will travel or what route it will follow. The only thing to say is that the vessel will reach the port eventually if nothing intervenes to hinder its course. What more can be said and what more can be expected? Prognosis cannot be an exact science, since we are never in possession of the data which are indispensable to a trustworthy forecast.

ERYTHROMELALGIA.

Of the two rare, interesting, and curiously contrasted diseases, *erythromelalgia* and *Raynaud's disease*, the former owes its birth and baptism as a new disease to Dr. Weir Mitchell, who, in his original description, tells his readers that "Erythromelalgia is a chronic disease, in which a part or parts of the body, usually one or more extremities, suffer with pain, flushing and local fever, made far worse if the parts hang down." The less rare condition of Raynaud's disease is one in which the extremities present a *symmetrical* display of indications of profound vascular and nutritional disturbance, in which pallor, congestion with lividity and local gangrene, are the characteristic features—in effect, "a local syncope, a local asphyxia, or a local death." Dr. Skirving, of New South Wales, recently showed a case of the latter condition in a miner, æt. 36, of neurotic temperament, who had lived a life of hardship and exposure, but without specific history or existence of discoverable organic lesion. He attributed his condition to the fact that he had "worked in wet claims." Eighteen months before he began to notice that both his feet at times "went dead." They became pale, sodden-looking, and cold to the touch. At the same time tactile, painful, and thermal sensations were equally blunted. There was never any dissociation of sensibility, such as is sometimes met with in other neuro-trophic lesions, of which syringomyelia is an example. There had never been much pain, seldom any cyanotic lividity, and never an approach to gangrene. A patient suffering from erythromelalgia was shown to emphasise the contrast. He was forty years of age, and was also neurotic, perfectly temperate, and without specific history. His present trouble commenced last autumn, after a long period of overwork and worry. He first noticed pain and throbbing in the left fingers, and uncomfortable sensations in the hands developed by degrees. Tactile sensibility appeared somewhat heightened; the other sensations remained normal. The fingers became red and hot; at the time of exhibition they were "somewhat swollen"; and they "show at times a tense, rosy glossiness." All the conditions are aggravated when the hand hangs down. Stress is laid on the fact that no stage of pallor preceded the hot, flushed condition of these left digits. There is some loss of muscular power, and there is diminished response to both forms of electric current, especially the faradaïc. When the affected fingers develop their full tint of rosy redness they sweat profusely The symptoms are least troublesome in the morning and increase towards night. Those two cases of rare disease are indeed curiously contrasted. The symmetry of the one and the asymmetry of the other are almost as definitely opposed as the vaso-constriction of the former and the vaso-dilatation of the latter. With regard to the primal origin of the conditions, it is probable that in the case of Raynaud's disease the view first propounded by the discoverer still holds its own, viz., that the vasomotor centres are unduly irritable, and that the exciting cause is usually from the periphery, for example, cold, and that efferent impulses from the centre lead to paroxysmal contraction of the arterioles. For erythromelalgia, the nearest approach to a satisfactory explanation of the conditions present—although by no means a perfect one—is offered by the suggestion of peripheral neuritis of vaso-motor fibres only.

Notes on Current Topics.

Mysophobia.

As the poet says, "Everybody worth a straw Has in him got some little flaw." In a fairly numerous class of persons this flaw—for all excess is a flaw—takes the form of an extreme horror of dirt—morbid fastidiousness—which a learned Frenchman has labelled "mysophobia." We are all familiar with victims of this special "phobia," though not under this scientific name. A person suffering from mysophobia, on taking his seat at table, begins by scrutinising closely every article placed there for his use; he holds his tumbler up to the light to see if it is free from finger marks, he scans his napkin to make sure that it is immaculate, and one by one each object is critically passed in review. In advanced cases the sufferer mechanically wipes the various articles, using the napkin for the purpose. In persons of a certain social standing mysophobia is a troublesome complaint—not to the victim, but to his entertainers. In a domestic servant, on the other hand, the affection constitutes a desirable quality, but unfortunately it is extremely rare in the servant and working classes. The prognosis is grave in the sense that the sufferers rarely recover, the tendency being for the affection to become more and more pronounced with advancing years.

A Typhoid Fever Prophylactic.

THE scourge of all modern armies is typhoid fever, and during the South African war the British lost more men from the disease than from the Mauser of the enemy. Yet the Boers practically suffered nothing from the disease, although their surroundings at Paardeberg were as insanitary as any camp could be. They had no drugs nor ambulances there, and very few of either elsewhere. General Lucas Meyer ascribes this immunity to the use of buchu, the value of which they learned of the natives. Buchu, bookoo, or bucku, was introduced into this country in 1774, and was in 1797 the subject of a monograph by C. J. Penz. Its medicinal virtues were extolled by Reed in 1824, since which time it has found a place in medical practice. Its value in chronic diseases of the genito-urinary organs, pyelitis, cystitis and vesical irritation are known to all practitioners. From chemists we have learned that the leaves yield a volatile oil containing about 30 per cent. of a crystalline diosphenol, together with menthone and a hydrocarbon. But no notice was taken of Burchell's description of the use of the leaves by the Hottentots, who used them for almost every disease. Waring states that the leaves possess tonic properties, but he is almost alone in that opinion; yet if taken in large quantities as Thompson recommended, it might reasonably be supposed to affect the alimentary canal, as given in ounce doses three times a day it is eliminated by the kidneys. The fact remains that the Boers on the veldt, according to General Lucas Meyer, had not a case of typhoid fever, and they ascribe their freedom from the disease to the use of buchu, as recommended by the Hottentots to the first Dutch settlers in the Cape. Whilst the subject is fresh in the minds of those who took part in the war we think some inquiries should be made to test the accuracy of the statement. It seems strange that the loyal British of Cape Colony and Natal should be ignorant of the valuable therapeutic properties of an indigenous plant, and we should consider it incredible were it not that for centuries the properties of digitalis remained unknown to the medical profession in England until Dr. Withering learnt them of an old woman who lived by curing dropsy with foxglove tea.

Relief *vice* Cure.

SOME of our nursing and drug-trade contemporaries have waxed facetious or censorially critical in respect of the practice of treating such a disease as pulmonary tuberculosis by cough medicines, digestives, and stomachics. Their attention was apparently directed to the subject by some remarks made by Dr. Arthur Tatham in a paper read before the Hunterian Society, in which he alluded contemptuously to the idea of obtaining a "cure" by any such means. But who anticipates a "cure" from this or any other purely medicinal treatment? Certainly not the intelligent practitioner, who knows full well that tuberculosis is not to be conjured by pills and potions; possibly the patient takes a sanguine view of his prospects, but even he, poor man, hopes rather than believes. Moreover, is it not the recognised duty of the physician to seek to mitigate the symptoms of diseases admitted to be incurable? And can it be denied that the administration of "some pernicious form of opium" tends to assuage the discomfort of the night-cough, just as a gentian-and-soda mixture restores the appetite? Does not the sufferer gain in weight and comfort under the administration of malt and oil? Are we not to give morphia to allay the pain of biliary colic merely because its effect is not curative? To the editor of the *Hospital* it may appear amusing to assert the descendance of symptomatic medication from witchcraft and sorcery, forgetful of the fact that when disease has reached an advanced stage palliative measures are the only means available, not to avert the inevitable but to prevent the preventible. There is no analogy between treatment directed to the relief of pain and recourse to "patent medicines" of unknown composition and uncertain action, and to assert that there is infers a singular inability to grasp the facts of the case.

The Bacteriological Diagnosis of Typhoid Fever.

Drs. Ferdinando Strado and Agostino Pasin have recently commented on their experiences of the value of Pioskowski's method of bacteriological diagnosis of typhoid fever. The method is as follows:—Normal human urine, of a specific gravity of 1020, is allowed to become alkaline spontaneously for from twenty-four to forty-eight hours; is peptonised with ½ per cent. of peptone; is then treated with 33 per cent. gelatin, by boiling over a water-bath for an hour; is filtered without the addition of heat; and is then poured out into test tubes. It is then sterilised at 100° C. for fifteen minutes, and on the next day a second time for ten minutes. According to Pioskowski, colonies of typhoid bacilli may be differentiated in this medium after twenty hours from those of the *bacillus coli* by the presence of long processes in the periphery of the colonies, prolongations which may reach to a length double that of the diameter of the colonies. In twenty out of twenty-two cases, positive, &c., salts were obtained by the employment of this method. The cultures must be maintained at a uniform temperature of 22° C., because a higher temperature causes liquefaction of the gelatin, and a lower one retards the development of the germs. The urine of individuals who have been placed on a purely vegetable diet should alone be employed in this method. The degree of alkalinity should not exceed a certain limit; so that the medium, after the addition of the gelatin, shall have but a very slightly alkaline reaction. The cultures employed must be fresh, as the differentiating characteristics disappear from old cultures.

Leeches in the Larynx.

The custom of drinking directly from streams and small lakes in France, Germany, and Italy, not infrequently enables leeches to find their way into the human organism. M. Rueda has collected some twelve such cases, two of which occurred in his own practice. Of these one was a country patient, who for five days had been suffering from dyspnœa and spitting of blood. In an attempt to catch the leech with a forceps a violent paroxysm of coughing was induced, during which the leech was expelled. Dr. Healy, I.M.S., reported in 1838 the successful removal of four leeches from the pharynx of a patient who had drunk some turbid water some days before. M. Billon, Clementi, Perez, and others, have published cases of their presence in the larynx, and Dr. Neale *(Medical Digest)* enumerates quite a number of such cases. One of the great dangers of leeches in the air passages is the passage of blood into the finer bronchi causing pneumonia. They should therefore be removed as soon as possible. Tracheotomy is very seldom necessary; when seen they may be withdrawn by a laryngeal forceps, though they are sometimes difficult to pull from their attachment, especially if they have just commenced to bleed; in these conditions M. Billon and M. Villions found that a whiff or two of tobacco smoke caused them to loosen their hold and to be expelled by the coughing the tobacco smoke caused.

Heat as an Antipruritic.

Professor Edmund Andrews, of the North-Western University, Chicago, recommends the application of heat—as strong as can be borne—as an effectual means of obtaining relief in the very troublesome and very persistent itching of pruritus ani. He was led to its adoption by the way in which he had seen northern farmers in the winter treat their "acute pernios," or chilblains. Those formations have regular periodical exacerbations of pruritus. "Once in twenty-four hours they awake into special activity, and afflict the patient with violent itching, which lasts some two hours or more." The patient at the onset of this itchy paroxysm exposes the chilblains to the greatest heat he can bear by taking off his boots and stockings and holding the affected toes opposite the red-hot coals of his stove. After each pernio has received this attention for a couple of minutes the patient feels no more itching there for the day. Dr. Andrews has devised an ingenious form of (closed) pipe through which a continuous flow of hot water can be maintained by a tube connected with an elevated reservoir. An axial outflow current is provided for by a tube placed similarly to that of a soda-water syphon. The investing closed cylinder is inserted to a distance of two inches beyond the anal margin. The highest temperature which can be tolerated is about 130° F., but many patients cannot bear a temperature above 125°, and he has never found any one who could endure 140°. The results are always soothing and it is claimed to afford more than mere temporary relief.

The History of Cannabis Indica.

Since O'Shaughnessy sent to his friend Dionysious O'Donovan, of Dublin, some specimens of the cannabis indica and of its preparations, and especially since the publication in 1839 of his great work, "On the Preparation of India Hemp," the drug has held a place in the physician's armamentarium. Withal it is an uncertain therapeutic agent, uncertain in the sense that its preparations, as they reach the physician, give very unequal therapeutic results. Its physiological effects sometimes justify the native names, "increaser of pleasure," "exciter of desire," "cementer of friendship," and the "laughter-mover." At other times it seems inert. Christison, in 1851, published a very able and interesting contribution to the therapeutical history of the drug, and soon after G. Martins issued his essay "Pharmakologisch-medichinische Studien über den Hanf," and in 1870 Clouston's "Observations on the use of Cannabis Indica in Insanity" appeared. We have referred to these distinguished writers to show the hold that the value of the drug had upon independent and practical physicians. The profession to-day is in no sense lacking in interest in this valuable drug, and during the Pharmaceutical Conference in Dundee "cannabis indica" was the subject of a series of very valuable papers—papers that offer a hope that the uncertainty of action of the drug will be practically unknown to the coming generation of medical practitioners. Dr. Marshall's review of recent work in this direction is not only an excellent summary, but it is a readable and valuable account of our existing knowledge on the subject. He advocates the use of the potent and stapie charas for making preparations, and would dispense with the official ganja. Charas is the resin obtained from the flowering tops of cultivated female plants. It forms a greenish-brown, moist resinous mass. Ganja, hitherto considered to contain the active therapeutic property of the plant is also obtained from the flowering tops of the female plant, deprived as much as possible of leaves. To decide on the relative values of these preparations the effects should, as O'Shaughnessy practised, be tried on the lower animals. And as gunja is known to deteriorate by keeping, O'Donovan's suggestion that the medicinal preparations should be made in India from the fresh plant might be acted on with good results.

The Abuse of Hypnotics.

One of the pitfalls for a young practitioner is the use of hypnotics. He commences confident in his power of curing pain. All around him he finds sedatives and hypnotics. To the list of the old narcotics which exercised Harley's classic pen is added the abundant supply of the synthetic class of chemicals. And yet how powerless the practitioner feels at the bedside of a maniacal patient for whom sleep is a necessity of life. Then for the first time perhaps he finds the truth of Sydenham's advice, "prescribe for the patient." The high fever, the staring eyes, the wild mutterings are indications not for the ordinary hypnotics old or new, but for the administration of some therapeutic agent to lessen the frequency of the pulse, to lower temperature, to abate the violent headache, and induce natural sleep. For such cases hypnotics are of no use. The disturbed action of the heart must be corrected, the arterial tension diminished, the skin made to act. The choice of the prescriber lies between aconite and green hellebore, and the dose should be small and repeated every five minutes until the effect of the drug is seen. Of aconite, two-drop doses repeated for twelve or even twenty times. When prescribing green hellebore, Norwood's tincture may be given in one-drop doses until the patient vomits or the physiological effects are produced. The action is similar to that produced by the antimony draught of Graves, which we have lost the art of prescribing.

Bifid Scrotum.

An unusually interesting case of this congenital deformity, in a man forty years of age, was recently published. The division passed from before backward, two distinct pouches being formed. As in the majority of such cases the man was a hypospadian, the urethral opening was small in extent and close to the extremity of the penis. The peculiarity in this particular case is that the deformity is associated with such little malformation. Fissure of the scrotum associated with cryptorchidism, a not unusual teratological condition simulates the vaginal orifice; the scrotal portion resembling the labia majoriæ, and such deformed persons are often exhibited to the public as hermaphrodites. It is sometimes a matter of difficulty to secure positive evidence of their sex, as in the case of Caspar's patient, K., who lived for thirty years as a woman, and would probably have died in ignorance of his sex had not the great medical jurist been consulted. The error in not recognising the sex is probably due to the fact that such persons seldom have a distinctive masculine appearance, and the condition closely resembles cases of enlargement of the clitoris, which are less infrequent than is commonly supposed.

Poisons and Race.

It is an interesting study in anthropology to inquire what are the commonest substances used in different countries as poisons. Thus, in this country, one would probably think of carbolic acid, opium, and strychnine, as among the most usual drugs employed with suicidal or homicidal intent. The first mentioned is perhaps responsible for more deaths than any other drug in recent years, though this is due to the ease with which it can be obtained. In France the commonest form of suicide is, of course, poisoning by carbon monoxide and dioxide gas from a lighted brasier. The report of the Chemical Examiner for Madras for the year 1901, recently published, gives some interesting information as regards the poisons used in India. Thus, among ninety-two cases of poisoning which came under inquiry, in only one was carbolic acid the agent used. Strychnine is commonly used, as are also arsenic, mercury, madal juice, oleander and opium. In two cases aconite was employed, and as it is the duty of the examiner, where aconite is suspected, to satisfy himself of its presence by an experiment on himself, his post is certainly no sinecure.

The Treatment of Burns.

The correct treatment of burns has always led to considerable diversity of opinion among surgeons, and there are few simple injuries in which the results of treatment are so commonly unsatisfactory. This is due to the difficulty of devising any line of treatment which is at once comfortable to the patient and conducive to speedy healing, and the individual surgeon usually errs in one or the other direction. In former times, before the antiseptic system was fully applied to surgery, the tendency was almost wholly to such treatment as was pleasant to the patient, while nowadays it is usually in the opposite direction. An American practitioner, however, claims to have followed out for some years a plan which fulfils all the requisites of successful treatment. Among a list of "nevers" appear: Never use a dry dressing, never forcibly remove the skin, never use oils, never change dressings frequently. One could hardly sketch a system more opposed to the old routine when "never wet a burn" was the basis of practice and carron oil the staple dressing. This treatment is simply the application of wet antiseptic dressings on the ordinary principles of the surgery of wounds.

Electrical Anæsthesia.

At the last meeting of the French Academy of Sciences, M. Leduc called attention to an ingenious method of inducing anæsthesia by means of the electric current which may possibly prove of service in respect of human beings, although, so far, it has only been tried experimentally on animals. The constant current is applied to the shaved head of the animal through an interruptor giving from 150 to 200 breaks a minute. The electromotive force is gradually but quickly increased until the body is thrown into a state of tonic contraction, when the animal falls down and respiration is suspended. The current is then reduced until respiration is restored, and at this stage the animal is in a state of quiet narcosis, cerebral activity being entirely suspended. This unconscious state can be maintained for at least two hours without injury, and consciousness returns as soon as the current is cut off. Not only has the experiment no injurious effect, but the animals were often particularly lively as if under the influence of a stimulant. When applied in the manner indicated, that is to say, quickly, the sensation, as far as one could judge, was not disagreeable, but when, on the contrary, the strength of the current was increased very gradually the animal passed through a period of clonic spasm. The current recommended is one of from 12 to 20 volts with 2 to 10 milliampéres intensity, and about 200 interruptions per minute. By this means, moreover, perfect anæsthesia of the region innervated by a particular nerve trunk can be painlessly obtained.

Hyperpyrexia.

Dr. L. Achard reports an interesting case of hyperpyrexia in a patient who had no pathological symptom other than slight bronchial rales. On taking the temperature in the arm-pit he was astonished to find it 108·6° F.; and in the evening of the same day it stood at 104° F. The following day the patient was visited by Dr. Achard and some medical friends, when the temperature was found to have reached the extraordinary figure of 110·5° F. It now commenced to fall, and two hours later stood at 104° F., and in the evening the thermometer recorded 102° F. Twenty-four hours later the fever gradually subsided, and the temperature became normal without any untoward symptom. In the anxiety to discover some morbid condition of the lungs the hyperpyrexia was overlooked until it had actually attained 110·5° F. Fortunately for the patient the abnormally high temperature passed away as quickly as it came, without leaving any organic lesion. We have become so accustomed to associate high temperatures with organic changes, to measure the severity of the case by the thermometer, and to base the prognosis on its rise and fall that cases which emphasise the unwisdom of being guided by any one symptom or group of symptoms, to the exclusion of the consideration of all symptoms of the case and the power of endurance of the patient, are likely to convey a much-needed lesson.

Meat Diet in Renal Disease.

It is customary to recommend the consumption of white meat in preference to red in cases of chronic nephritis, on the ground that the ingestion of red meat exerts a prejudicial effect on the albuminuria. Dr. Kaufmann, of Frankfort, has just published a series of observations which he has carried out in order to determine whether or not this rule of practice has any scientific foundation. As a matter of fact, he found that the particular kind of meat ingested had no obvious effect on the nitrogenous excretion or on the urinary albumin. In the same patient the variations in the quantity of albumin in the urine took place quite independently of the nature of the diet, the maximum albuminuria sometimes coinciding with a milk diet, at others with the administration of white or red meat, indeed in some observations the substitution of red for white meat was followed by a reduction in the amount of urinary albumin, so that, on the whole, he is inclined to attribute these oscillations to causes other than dietetic. It follows that if the condition of the patient be such as to allow of his taking meat at all the kind of meat is not a matter of any particular importance.

Solanine in Potato Peel.

Students of materia medica are usually taught that the potato belongs to the same botanical family as belladonna, a fact which naturally excites a feeling of mild surprise. It seems, however, that the potato is not quite as innocuous as is generally believed. At an inquest held last week at Bristol on a child of eight, who had died under somewhat mysterious circumstances, the post-mortem examination revealed the fact that the stomach contained a large and varied assortment of edible articles, among them sundry pieces of potato peel, to the toxic constituents whereof, according to the medical evidence, death was due. A verdict was returned in accordance therewith, but if really death can be caused by eating raw potatoes it is as well that we should be made aware of the fact, although the raw potato is not usually regarded as edible except by the omnivorous child. The evidence contained in the report before us does not enable us to offer an opinion as to the likelihood of this hypothesis being the correct explanation of the fatal result. It is at least plausible that the ingestion of several slices of raw potato *plus* a large quantity of fruit, presumably also raw, may have determined an attack of acute dyspepsia capable of causing death. We are unable to discover any evidence in support of the view that potato peel contains a sufficiency of toxic principles to cause death.

The Work of the Royal Commission on Tuberculosis.

The sensational declaration of Professor Koch at the recent Congress on Tuberculosis led to the appointment of a Royal Commission last September, and this called forth the generous offer of Sir James Blyth to place two of his farms at the disposal of the Commission. Work has quietly but steadily been progressing at Stansted, in Essex. Suitable buildings have been erected, and experts are carrying out an elaborate series of experiments and observations, but it will be some time before any authoritative statement of results can be expected. Our illustrated contemporary, the *Graphic*, in the current number, gives interesting views of the farms at Stansted and Bishop Stortford, lent to the Government by Sir James Blyth. This happy combination of State aid and philanthropic private assistance is in thorough accord with the best British sentiment, and much benefit is likely to accrue not only to the Empire but to the whole world.

Notification of Phthisis.

A certain degree of voluntary notification of phthisis has been carried on in this country in Manchester, Oldham, Brighton, and some few other places. Efforts have been made to secure compulsory notification, but hitherto without success. The authorities of the Local Government Board, with cranial fettering of red tape, effectually bar progress. In this, as in so many other matters of reform, it would seem pressure must come from without, and we must be frightened into action by the progressive movements of foreign countries. The Austrian Home Office has recently issued an ordinance compelling the employment of prophylactic and hygienic measures against tuberculous infection. Every case of tuberculosis is to be notified. Germany will doubtless quickly follow suit, and of course finally the Local Government Board will be compelled to agree to compulsory notification.

Small-pox in Barbados.

A smart outbreak of small-pox has occurred in Barbados, and according to recent reports is rapidly spreading. Great difficulty has been experienced in obtaining medical assistance for the victims, the resident physicians declining to lend their aid, and it has been found necessary to import a young practitioner for the purpose. The supply of vaccine promptly ran out at the first alarm, and supplies have had to be obtained from America and England. Owing doubless to climatic influences much of the lymph has proved unsatisfactory, and public opinion is strongly expressed on the subject.

The Illness of Professor Virchow.

Recent telegrams from Berlin represent the illustrious professor to be in a very critical state of health. He has been staying in the Harz mountains, whither he betook himself on recovering from his accident of a few months since. The shock caused by his injury is no doubt the source of the prostration from which Professor Virchow is now suffering, and in view of his advanced age it cannot be denied that his state is such as to justify anxiety. The latest telegram states that his removal to Berlin on Monday last was fairly well borne.

The Pawn-shop and Disease.

The pawn-shop is an important factor in our social system. The comfort, if not the existence, of a large section of the community may be said to depend upon its presence. Where poverty exists the pawn-shop flourishes. The association is not unnatural. Certain of its most manifest evils have been controlled by legislative enactments. But it is remarkable that the part which the pawn-shop plays in the spread of disease has been to a great extent lost sight of. And yet, as is well known, clothing affords a ready means for the spread of many forms of infectious disease. We venture to think that it would be well for the community if medical officers of health devoted more attention to this matter and were provided with greater powers for securing a nearer approach to hygienic conditions in all pawn-shops.

The Prophylaxis of Hæmophilia.

The precise nature of the curious condition of the blood exemplified in hæmophilia is still a mystery; indeed, we have not heard of any plausible explanation of the non-coagulability of the blood in the subjects of this distressing and often dangerous abnormality. Empirically, however, it is possible to do much to ward off the disastrous consequences of this organic defect. By the administration of chloride of calcium, for instance, the coagulability of the blood can to some extent be restored, and even more satisfactory results are afforded by the administration of gelatine by the mouth. This should be given in daily doses of half an ounce, a quantity which can easily be taken without any change in the ordinary diet. It is worthy of note that the influence on the plasticity of the blood of the ingestion of gelatine is also productive of good effects in albuminuria.

A Record Swim.

The remarkable performance of Montagu Holbein merits the highest praise, and will long rank among the most famous of physical achievements, for it affords a wonderful demonstration of human endurance. To have remained for over twenty-two hours in the sea and travelled something like forty-five miles must be accounted a record which will not readily be beaten. Holbein is forty-one years of age, and has spent many years in contests of physical endurance. His latest feat offered much material for interesting physiological observations, and we hope scientific data may be forthcoming which may at least to some extent extend our knowledge of the problems connected with long-continued exercise, and the near and remote consequences of fatigue.

Tramcar Scrimmages.

The fatal injury recently reported as resulting from the rush to the tramcars at Blackfriars Bridge has drawn attention to the need for reform in our methods of tramcar loading. The violent scrimmages which are everyday occurrences in many of our large centres of industry are not only serious breaches in courtesy, but give rise to physical dangers and mental distress. Difficulties have arisen in securing a procedure which shall be simple and yet effectual. The queue, the number system, and the sheep-pen method all have their drawbacks ; but, if the present unseemly and dangerous proceedings continue, some manner of relief must at all costs be secured in the interest of women and children, and to preserve humanity from some of the worst manifestations of animalism.

The Soldier's Feet.

Feats of military prowess depend in great measure on the feet of the average private. We are glad to see that even the slow-moving War Office is beginning to realise the importance of providing soldiers with a good understanding. We hear that "the War Office authorities are considering the best means of preventing men falling out of the ranks with sore feet." Each battalion, it is said, has been provided with a chiropodist. It seems that the German principle of pedal protection may be enforced. But will the conservative spirit of the British soldier allow him to give up the time-honoured advice, "Just drop some tallow in your socks and that will make 'em well ?"

Proposed Memorial to Capt. E. G. Forrest, R.A.M.C.

It has been proposed by some of the many friends of the late Capt. Forrest, of the Royal Army Medical Corps, whose early death we recorded some short time ago, to erect a memorial to him either at Aden, in which place he died, or at his home in Ireland. Subscriptions are to be limited to ten rupees (13s. 4d.), and should be sent to Capt. A. H. Waring, R.A.M.C., No. 1 Section Hospital, Secunderabad, India. Many of his friends who were connected with him at College or in the Army Medical Service will doubtless be glad to join in this memorial.

The Resuscitation of the Still-born.

Rhythmical traction of the tongue has been highly lauded as a substitute for artificial respiration in attempting the resuscitation of apparently still-born infants, but this procedure, though of unquestionable utility, has the drawback of being somewhat difficult of application in these cases on account of the difficulty of obtaining and retaining a firm grip on the little tongue. As an alternative it is pointed out that rhythmical pressure on the base of the tongue by the finger introduced through the mouth answers the same purpose, and at the same time it has the advantage of freeing the upper air passages from any accidental cause of obstruction.

Whooping-Cough.

Dr. Arnat recommends the inhalation of iodide of ethyl as a means of cutting short paroxysms of whooping-cough. No apparatus is necessary : the stopper is removed from the bottle and the patient merely inhales the vapour. It is claimed to be peculiarly serviceable in the cough of children from two to five years of age, and in those in whom the paroxysm terminates in vomiting, or in suffusion of the subconjunctival vessels.

PERSONAL.

Dr. James Goodhart will take the chair at the Guy's Hospital Old Students' Dinner, on October 1st.

Dr. F. W. Clark, Medical Officer of Health for Hong Kong, has been nominated a member of the Legislative Council of that colo ny.

Mr. Godfrey H. Hamilton, Secretary to the British and Foreign Blind Association, has been appointed Secretary to the National Hospital for the Paralysed and Epileptic.

Surg.-Gen. Sir W. D. Wilson, K.C.M.G., is expected back from South Africa to take up the Principal Medical Officership of the Third Army Corps in this country, in succession to Surg.-Gen. A. F. Preston, retired on the age limit.

Dr. William Palmer Wynne, F.R.S., Assistant Professor of Chemistry in the Royal College of Science, South Kensington, has been appointed to the chair of Chemistry in the School of Pharmacy of the Pharmaceutical Society of Great Britain.

Dr. W. H. Drummond, who is now on a visit to England, practises medicine in Montreal and lectures on Medical Jurisprudence in the University of that city, but it is as a novelist of considerable power and great originality that he is chiefly known. In his works, "The Habitant and other French-Canadian Poems" and "Johnnie Courteau," he has given us remarkable portrayals of early French-Canadian life.

For the time being Sir Frederick Treves cannot be said to have any "private life." Enterprising journalists have been "grubbing" into his history and antecedents, and have made public all that, in their estimation, was not "unfit for publication." We learn, not without surprise, that Sir Frederick, as a schoolboy, though by no means destitute of abilities, was "somewhat sluggish, moody, and silent"—a lad who "cribbed when he could, read Dumas and Mayne Reid by stealth, and manœuvred as many holidays through indisposition as he possibly could." This fragment of history reads like a paraphrase of Mark Twain's famous story about the good Jimmy who was drowned on his way back from Sunday-school, and the bad Jimmy who played truant, and spent an altogether enjoyable afternoon, getting home in good time for tea.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

At a meeting held last week the Board of Guardians adopted the report of the Committee appointed to consider Dr. Smyth's (Local Government Board Inspector) report of the inquiry relative to the excessive expenditure on medicines and medical and surgical appliances. They recommended that the minutes of the evidence taken at the inquiry be printed, and that each guardian be furnished with a copy of the same.

The Annual Report of the President of Queen's College, Belfast, has just been published, and, as usual, contains much matter of interest. It records the resignation of Professor W. H. Thompson, who for nine years had held the Chair of Physiology, leaving it to take up the duties of the King's Professorship of the Institutes of Medicine in Trinity College, Dublin. It further records the resignation of Dr. R. O. Cunningham, who held the Chair of Natural History for about thirty-two years. His striking figure will be missed at the Royal University examinations, as well as in Queen's College. Special reference is made by the President to the Royal University examinations for the degrees of M.B., B.Ch., and B.A.O., calling attention to the very satisfactory report upon them of the General Medical Council, from which several quotations are given.

An important section of the report deals with the great advances made of recent years in the facilities offered for post-graduate work, though the fact is not mentioned that the credit for starting this is due to Professors W. H. Thompson (in physiology) and Lorrain Smith (in pathology). Their excellent example has now been followed in various other departments not strictly medical, and a vast amount of useful work is being done. As the President mentions, two new sections have been started under the Professor of Pathology, one dealing with clinical pathology, under the care of Dr. Thos. Houston, who holds a research studentship of the British Medical Association, and one dealing with pathological neurology, under Dr. R. A. L. Graham, a past Henry Hutchinson Stewart scholar in mental diseases.

The two chairs rendered vacant by the resignations of which the President speaks have not yet been filled, but must be so before the winter session opens. Much importance is naturally attached to the Chair of Physiology by medical men here, and the claims of rival candidates have been freely discussed. A point of special interest arises just now—whether or no the Professor of Physiology should necessarily hold a medical degree. It seems to be the fashion among young physiologists at the English Universities not to take medical degrees as they used to do, but the feeling here is that a man who does not hold such a degree ought not to be appointed to teach medical students. The teaching of such a man, however scientific, is apt to lack the practical bearing on clinical work which is so desirable in the physiological class-room.

Correspondence.

MODERN ASPECTS OF DENTAL SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—The dental profession should be gratified by the appreciative article under the above heading in your issue of to-day, August 27th. It would be easy to magnify unduly the importance of dental disease as a factor in production of general systemic disorders; but there can be no doubt that until late years the significance of this factor has been almost completely ignored. Until within the last twenty-five years a scientifically educated dental profession cannot be said to have existed. The majority of dentists were formerly mere mechanics, with very rudimentary, if any, acquaintance with pathology, even as pertaining to the dental tissues and the immediate connections of the teeth alone. Now in all large towns and many smaller ones there are to be found dental practitioners as highly qualified in their department as any other class of surgical specialists; men fully competent to help in the diagnosis and treatment of cases influenced by or due to dental disease or septic conditions of the mouth. Injuries and diseases of the teeth, besides having frequently a share in causation or aggravation of systemic disease, are as often associated with local surgical affections. Among these may be enumerated empyema of the antrum, ulcerations of the mouth and tongue, and wide-spreading cellular inflammation extending from the dental alveoli. The last-named cases, which are much more common than might be supposed, are often due to fracture of roots of teeth within their alveoli. Two cases ending fatally were recently reported. The dental lesions were not discovered before death by the surgeons in charge; and there seemed little doubt that if a dental surgeon had in each case been called in at first, and a correct diagnosis made, the lives of both patients might have been saved by timely removal of the dental cause of the mischief. A case of this kind was reported at a recent meeting of the Odontological Society. In this instance the case was seen at the outset by a dental surgeon, and the mischief was cut short in its initial stage.

I am, Sir, yours truly,

TURPENTINE AS A DEODORANT.

To the Editor of The Medical Press and Circular.

Sir,—In last issue under above heading, the outward application of turpentine is recommended. Small doses internally would be much more effective, and not only prevent obnoxious odour, but substitute an agreeable one, *i.e.*, the odour of violets.

Boric acid in 10 or 15 grain doses in egg-cup of milk, t. d., would also be found in practice in these distressing cases most valuable.

I am, Sir, yours truly,
Alexander Duke.

London.

CIVILISATION AND THE BIRTH-RATE.

To the Editor of The Medical Press and Circular.

Sir,—It is only in medical journals that the questions broached in your leader of to-day, August 27th, can be freely and fully discussed, and, as I pointed out during the correspondence which went on in The Medical Press and Circular on the same topic a few months ago, it is certain that the great number of scientific, albeit non-medical, readers of your valuable paper will be glad to see space given up to it on occasion. The population question in its aspect at the present day—so very different to what it was in the days of the early political economists—is of enormous interest and importance to the philosopher and the student of sociology, no less than to the statesmen. It is attracting more and more notice from all these classes, as is evidenced by the numerous articles in special and general newspapers, and discussions at scientific societies. A leader on the subject appears in *The Times* of Monday last, August 25th, one of many such articles with much correspondence recently published in your great contemporary. The subject came up, I notice, at the late meeting of the British Medical Association. A paper was there read by Dr. Charles Drysdale advocating the systematic artificial limitation of the family as the best remedy for pauperism. This seems to me most pernicious advice. Pauperism is rather a symptom of deeper-seated social disorders which are not curable save by removal of the root causes. If the practice of limiting the number of children be pushed in this country, as it has been for a generation or two in France, to its logical conclusion from the egotistical point of view, nothing can save the nation and the empire from the decay which has already put an end to the true greatness of France, and will surely terminate in degrading that hitherto splendid nation to the level of its effete neighbours, Spain and Portugal.

I am, Sir, yours truly,
A Student of Sociology.

August 29th, 1902.

Literature.

PRINCIPLES AND PRACTICE OF THERAPEUTICS. (a)

More than a quarter of a century has elapsed since the appearance of the first edition of Wood's well-known treatise on therapeutics. It is said to have been designed and completed in less than a year. It was "entered according to Act of Congress, in 1875, by J. B. Lippincott and Co., in the office of the Librarian of Congress at Washington." It was described as "a work on medical agencies, drugs, and poisons, with especial reference to the relations between physiology and clinical medicine." It has now reached the dignity of an eleventh edition, and the author has associated with himself in its production his son, Dr. Horatio C. Wood, jun., Demonstrator of Pharmaco-dynamics in the University of Pennsylvania. Although described as a treatise on therapeutics, it has always been regarded as the leading work in the English language on pharmacology. From the clinical point of view it is less practical and less suggestive than the works of S. Ringer and C. D. F. Phillips. The present edition has undergone many modifications, and by a judicious arrangement of type an attempt has been made to bring it more in accord with the requirements of students. The plan of giving a summary of the actions of each drug or of each group of drugs is an innovation and is distinctly useful. The references are now arranged at the end of each article instead of being scattered throughout the text or referred to in foot notes, and this, again, is a distinct advantage. The plan, however, has certain disadvantages from the point of view of the authors, for the reader familiar with the subject more easily detects omissions and is in a better position to detect inaccuracies. In a text-book of this description a large amount of boiling down is essential, and in many cases this seems to have been done not too judiciously. It requires a master-hand to determine what to accept and what to reject, and in this respect judgment is sometimes lacking. Articles of little moment are quoted at length, whilst others of primary importance are but briefly mentioned, or are passed over in silence. We must admit that we do not place the same implicit trust in much of the work contained in this volume as was freely accorded to, say, the seventh edition. What may be the explanation of this we do not know. The authors are sufficiently outspoken, and for this they deserve much credit. For example, in dealing with disinfectants they point out that there are not many affairs in life in which the public have been so superabundantly fleeced as in this particular matter. "A most extraordinary part of this swindling is the ease with which distinguished members of the medical profession have given certificates of efficiency to comparatively inert and extraordinarily expensive proprietary compounds." A list is given representing from the pecuniary side of the question the comparative germicidal power of various drugs. Corrosive sublimate is the cheapest, whilst carbolic acid comes a long way down. This table is worth studying by those who are in the habit of ordering disinfectants in large quantities.

In dealing with pharmacological actions the authors are at their best, but they seem to be wanting in the tact and experience of the old therapeutic hand. They have done well to ignore the preparations of the Pharmacopœia, which are entirely out of place in a work of this description. The average prescriber has a deep-rooted belief that if he knows his pharmacopœia he is a pharmacologist. This idea is fostered by the fact that students in England (this does not apply to the Scotch universities) are not examined in pharmacology, and that they are not required to display anything more than the most elementary knowledge of the action of drugs either in health or disease. Pharmacology, which is the basis of all rational treatment, is a lost art in this country. Pathology and bacteriology are for the moment in the ascendant, and it may be some years before the school of English pharmacology is revived. Fraser and Stockman continue to do good work in Scotland, but more investigators of this stamp are sadly needed. Wood's Therapeutics is a great work, and is of inestimable value to those whose business in life it is to deal with the actions of drugs.

CLINICAL HÆMATOLOGY. (a)

Enormous advances have been made of late in the study of diseases of the blood, and in this category we include not only the various forms of anæmia such as secondary anæmia, chlorosis, pernicious anæmia and splenic anæmia, but lukæmia, both of the lymphatic and spleno-myelogenous varieties, lymphadenoma, purpura, scorbutus—land, sea, and infantile—and hæmophilia. So much depends for their differential diagnosis on a study of blood counts that some knowledge of the subject is required not only from the hospital physician but from the general practitioner. Post-graduate classes have been established in connection with many of our general and special hospitals both in London and in the provinces, and there is an increasing disposition on the part of those engaged in active practice to avail themselves of the opportunities so afforded. But there must always be a certain percentage of men who, from their distance from medical centres, cannot afford the time to take out courses of practical instruction. For them the only substitute, if they wish to prevent themselves from falling hopelessly behind in the struggle for existence, is a careful study of well-arranged text-books. Of these there are many dealing with various branches of medicine, surgery, and therapeutics, but a good work on clinical hæmatology has long been a desideratum. The apparatus required for these investigations is very inexpensive—a moderately good microscope, a few slides and cover-glasses, and half a dozen bottles of reagents and staining-fluids. With this simple outfit and a good text-book the novice may fairly hope in the course of a few months to obtain a knowledge of the subject which will place him in a position to deal with a common and very important group of diseases. The anæmias alone are worth consideration for the practitioner who mistakes a case of Banti's disease for one of chlorosis, and gives his prognosis accordingly, must of necessity sustain professional damage.

Many excellent works on the clinical examination of the blood have been published during the last four or five years, and among them may be mentioned the elaborate treatise of Cabot, of Boston, a book of some 500 pages. Dr. Da Costa's work contains about the same number of pages with eight full-page coloured plates, three charts, and forty-eight illustrations, all of which are excellent. The author has arranged his facts in a form which cannot fail to enlist the sympathies of his readers. He is thoroughly practical, and displays an exceptional knowledge of all branches of this somewhat difficult subject. The book deals not only with diseases of the blood, but includes general hæmatology. Information of a practical and useful character is given respecting bronchitis, influenza, diphtheria, diabetes mellitus, enteric fever, gastric ulcer, gout, and other common complaints. The differential tables are excellent, and from a clinical point of view are of the greatest value in diagnosis. We cannot find fault with a work which possesses so many good qualities, but we may point out that under the head of splenic anæmia the author has done scant justice to the classical researches of Guido Banti, of Florence. In speaking of spleno-medullary lukæmia he seems to be unacquainted with the occasional complication of the disease with tuberculosis. This condition, we admit, is extremely rare, but the few cases which have been recorded have been by American authors. Taking it on the whole, we have no hesitation in saying that it is the best work on clinical hæmatology in the English language.

(a) "Therapeutics: Its Principles and Practice." By Horatio C. Wood, M.D., LL.D. Eleventh Edition. Remodelled in great part and rewritten by Horatio C. Wood and Horatio C. Wood, jun., M.D. London: Smith, Elder and Co. 1902.

(a) "Clinical Hæmatology. A Practical Guide to the Examination of the Blood, with Reference to Diagnosis." By John C. Da Costa, jr., M.D., Jefferson Medical College. London: Rebman, Limited. 1902.

SANITARY ENGINEERING. (a)

The author has approached his subject from the standpoint of practical experience, and, although the book contains some statements which will evoke considerable criticism, and with which we do not ourselves agree, may be said to have accomplished his task with reasonable success.

The opening chapters, dealing mainly with hydraulics and mathematical formulæ, an accurate grasp of which is essential to a thorough knowledge of the subject, contain much valuable information of a practical nature. Drainage and sewerage are dealt with in the succeeding eight chapters in a manner which is on the whole admirable, though we cannot say we find ourselves altogether in accord with some of the author's recommendations. For instance, on page 57, it is laid down that "drains from water and other closets should be at least 6 ins. in diameter." This, we think, is not the size usually adopted for, at all events, small and medium-sized houses, nor is such a large bore necessary. Neither can we agree with the author's contention that, because a smaller drain may become choked through improper usage a larger one should be substituted. Again, while the danger of laying gas and water mains inside a sewage culvert is very properly pointed out in Section 150, nevertheless in a later chapter (Section 359) we find the placing of sewers, gas, water, and electric mains in a common culvert under a river actually recommended. Apart from any possible danger consequent on the close proximity of gas and electric mains, the inadvisability of water mains being laid in any way near sewers cannot we think, considering the rapidity with which water absorbs gases, be too strongly insisted on. Probably the best part of the book is Chapters 15 and 16, dealing with sewage disposal, the latter especially, which treats of bacteriological purification, being most interesting, and brought thoroughly up to date.

We do not find, either under the heading of sewer construction or elsewhere, any reference to the Durham system of using iron pipes, which has found much favour among some sanitary engineers, both in America and in this country. This omission is the more regretable, as the other systems are dealt with in detail. The sections on drain testing might be, we think with advantage, elaborated in a future edition. We are not inclined to place too much reliance on the smoke and pungent chemical tests which seem to find most favour with the author, to the exclusion of the water test only mentioned incidentally, and the compressed air test, as suggested by Gilbert Thomson, all reference to which is omitted.

The writer is at fault in his knowledge of sanitary law when he states (page 250) that "the Public Health Act, 1875, provides that every Local Authority *shall* undertake the removal of house refuse from premises." The section is permissive, but may be made compulsory by Local Government Board order. Further, Section 44 (P. H. Act) empowers the Local Authority to impose under bye-law such duty on the occupier of the premises.

Apart from these and a few minor faults the book is well written, and should prove of much value to all engaged in public health work. The illustrations are numerous and clearly drawn, while the general production of the work leaves nothing to be desired. We can commend it to all desirous of obtaining an insight into the principles of sanitary engineering.

DISEASES OF CHILDREN. (a)

When a book, no matter on what theme, reaches the seventh edition, it proves beyond all doubt that the subject of which it treats is important, that the demand for it is great, and that the matter therein contained has been duly appreciated.

Diseases of children are a part of the student's training which we think as a rule is very often very much overlooked or very superficially studied. We consider this a great pity, as children's ailments comprise a very large portion of the practitioner's work when engaged in the general practice of his profession. In the work before us the student has a manual which will give him a very extensive, useful, and practical guide to the diseases peculiar to infantile life. This edition, the author states, has been subject to considerable revision and rearrangement. The chapter on the feeding of infants is dealt with in a very comprehensive manner, and brought quite up to date. The various diseases are grouped in separate chapters, of which there are over fifty. The book comprises over 800 pages, is printed on good paper, and reflects credit on the author and publishers alike. After a careful perusal we strongly recommend this work as a safe and voluminous epitome of infantile diseases.

Laboratory Notes.

ANTIPHLOGISTINE.

(London Office: 18, Jeffrys Road, Clapham Road.)

This preparation appears to be admirably suited for the purposes for which it is intended, namely, as a soothing antiseptic poultice or dressing applicable to a great variety of cases.

It consists of a smooth homogeneous mixture of several chemical substances, the base being the silicates of alumina and magnesia in intimate alliance with pure glycerine, while the antiseptic property is conveyed by the presence of boric and salicylic acids. There are, in addition, other ingredients which in our opinion combine to make this preparation highly fitted for the purposes for which it is designed.

This preparation has met with success in America as a local application of great value in a large number of different classes of cases, and we would urge our medical friends to give it a careful trial, as we have satisfied ourselves by analysis that its composition corresponds with the ingredients stated in the excellent pamphlet that is issued by those who are responsible for its production.

SOME IMPROVED TOOTH POWDERS AND MOUTH WASHES.

The first essential quality without which it is out of the question to hope for the habitual use of a dentifrice by the average patient is, that it be agreeable to use and leave a pleasant after-flavour and feeling of cleanliness in the mouth. Messrs. Rouse & Co., chemists, of Wigmore Street, W., have sent us some improved tooth powders and mouth washes, and have communicated to us the full formulæ of these preparations, and inform us that they are based upon the principles laid down in Messrs. Sewill and England's work on "Dental Pathology and Surgery" (fourth edition recently issued). Seeing that caries cannot go on without occurrence of fermentation and putrefaction in the *débris* lodging upon the teeth, it is evident that much can be done to prevent dental decay by antiseptic treatment. Then again, when vitiation of the secretions of the mouth exists, it is of importance that this should be corrected to prevent injurious effects on the health. Messrs. Rouse's tooth powders and mouth washes, some of which are for ordinary use, some for cases where the secretions are foul, seem to be admirably adapted for their purposes, and should command the confidence of the medical profession, who rightly look with suspicion on secret cosmetic preparations, being well aware that these when not harmful are mostly useless for their purpose. A largely puffed tooth powder, recently analysed by us, proved to be made up mostly of common chalk and levigated pumice. Such a mixture would have the effect, no doubt, of whitening the teeth, but would do this by slowly grinding away their enamel and gradually destroying them.

(a) "Sanitary Engineering." By Francis Wood, A.M. Inst. C.E., F.G.S., &c. Pages xi. and 304. London: Charles Griffin and Co. Limited. 1902.

(a) "The Diseases of Children." By James Frederic Goodhart, M.D., LL.D.Aberd., F.R.C.P. Seventh Edition, with the assistance of George Frederic Still, M.A., M.D., F.R.C.P. London: J. and A. Churchill. Price 12s. 6d. net. 1902.

A Religious Mania in Canada.

It is a remarkable fact that in all ages and in all countries morbid psychological displays have assumed epidemic characters. Even in these matter-of-fact days of the twentieth century outbreaks of so-called "religious mania" occur even as in mediæval times. A remarkable example is reported from Winnipeg. The large colony of Doukhobors, recently planted in Manitoba, is the seat of affection. The entire colony, it appears, has been seized with religious mania. Its members have abandoned the use of horses, cows, and all domestic animals. The poor creatures have been turned adrift. Moreover, these infatuated people refuse to wear wool or leather because these are animal products. At all events, it would seem that the Doukhobors are more logical than some of our English anti-vivisectors.

The Polyclinic.

The Polyclinic and Post-Graduate College in Chenies Street reopens on September 8th.

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, August 23rd, 1902, represent an annual rate of mortality of 20·1 in every 1,000 of the population. During the week there were nineteen deaths from diseases of the nervous system, seventeen from diseases of the circulatory system, and eighteen from diseases of the respiratory system. In thirteen cases the deaths were uncertified, there having been no medical attendant during the last illness. Fifty-two infants died during the week, of whom twenty-nine were under twelve months old. Within the city the death-rates in the districts named were as follows:—Clarence Street North, 29·4 per 1,000; Blackhall Place, 28·0 per 1,000; Castle Street, 27·4 per 1,000; and Peter Street, 25·7 per 1,000.

The Weaning of Puppies.

Lemaistre has noticed that mother dogs feed their puppies with matter which they vomit for the purpose when lactation ceases. The substances vomited must be predigested and form a natural transition diet between milk and solid food. He therefore suggests that it might be possible to utilise peptones derived from herbivora or even carnivora in some such way, when an extremely nourishing predigested food is needed in the clinic. Gasterin, which is much used in therapeutics abroad, is merely gastric juice derived from living dogs.

St. Thomas's Hospital.—House Appointments.

The following gentlemen have been selected as house officers from yesterday, September 2nd:—

House Physicians.—A. D. Hamilton, M.B.Lond., L.R.C.P., M.R.C.S.; C. H. Sedgwick, M.A., M.B., B.C.Cantab.; H. W. Sinclair, M.B.Lond., L.R.C.P., M.R.C.S. (extension); K. E. Crompton, B.A., M.B. B.C.Cantab. (extension).

Assistant House Physicians.—W. H. Harwood Yarred, B.Sc.Lond., L.R.C.P., M.R.C.S.; A. Mavrogordato, L.R.C.P., M.R.C.S.

House Surgeons.—W. Hill, B.A.Cantab., L.R.C.P., M.R.C.S.; J. Coates, L.R.C.P., M.R.C.S.; A. C. Hudson, M.A., M.B., B.C.Cantab.; H. Spurrier, B.A.Cantab., L.R.C.P., M.R.C.S.

Assistant House Surgeons.—J. W. Rob, B.A., M.B., B.C.Cantab.; T. B. Henderson, M.A., M.B., B.Ch.Oxon.; J. P. Hedley, M.A., B.C.Cantab.; A. B. Bradford, L.R.C.P., M.R.C.S.

Obstetric House Physicians.—Senior: R. E. Roberts, M.B., B.Sc. Lond.; Junior: F. J. Child, M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S.

Ophthalmic House Surgeons.—Senior: F. Clarkson, M.B., B.S.Durh.; Junior: A. E. A. Loosely, B.A.Oxon., L.R.C.P., M.R.C.S.

Clinical Assistants in the Special Department for Diseases of the Throat.—J. E. Adams, L.R.C.P., M.R.C.S.; S. G. Scott, M.A., M.B., B.Ch.Oxon. Skin: A. T. Waterhouse, M.A., M.B., B.Ch.Oxon., L.R.C.P., M.R.C.S.; C. Wheen, B.A., Oxon, L.R.C.P., M.R.C.S. Ear: F. H. Pearce, B.A., L.R.C.P., M.R.C.S.

Clinical Assistants in the Electrical Department.—O. Hildesheim, B.A., M.B., B.Ch.Oxon.

The Purity of Bottled Table Waters.

An American Board of Health has adopted an amendment to the sanitary code, looking to a standard of purity for artificial and bottled waters. Every manufacturer and importer or other persons who manufacture or import mineral spring or other drinking water will be required to file under oath with the Health Department the name of such water, the exact location from which the water is obtained, together with a chemical and bacteriological analysis thereof, also stating when the water was manufactured, the exact formula used in its production, giving qualitatively and quantitatively each and every item entering into its composition. Anyone failing to comply with these requirements will be refused a permit.

Cholera in Egypt.

The epidemic of cholera in Egypt has attained formidable dimensions. The fresh cases last week numbered 3,086, with 2,294 deaths, bringing the total up to 7,374 cases, with 5,540 deaths. Alexandria has remained practically free from the disease, and the ports on the Canal are not, so far, infected. The outlook is gloomy, the daily number of new cases averaging over 700, and no improvement is anticipated for some weeks to come. Active measures of isolation of infected districts and disinfection are being enforced.

Death of a Football Player from Tetanus.

The death of Mr. David Jones, the well-known football player, from tetanus following a wound received during a game, elicited from the coroner's jury sundry expressions of dissatisfaction concerning the way in which the wound was dressed on the field, their criticism being based on the fact that some "grit" and bits of grass came away from the wound after the removal of the deceased to the Royal Infirmary. Doubtless every effort should be made to cleanse such wounds of all foreign bodies, but it may comfort the relatives to know that the most thorough scrubbing and mauling of the wounded surface, even under an anæsthetic, have often failed to avert a subsequent attack of tetanus. A verdict of accidental death was returned.

A Roumanian Doctor at Nottingham.

An inquest was held by the Nottingham City Coroner on a child who had been attended by a Mr. Morris Martin, who claimed to be M.D. of Roumania, his diploma having been seized by the Boers, who had commandeered his services in South Africa. He gave the child medicine for diarrhœa, in contravention of the Apothecaries Act, but at the autopsy death proved to have been due to intussusception. Dr. Cran testified that the treatment was appropriate, and a verdict of "Death from natural causes" was returned.

Indian Medical Service.

The following is a list of the candidates for His Majesty's Indian Medical Service who were successful at the recent competitive examination held in London:—

	Marks.		Marks.
A. T. Pridham	3,162	P. G. Easton	2,542
F. P. Mackie	3,097	J. L. Lunham	2,522
F. P. Connor	3,032	W. J. Collinson	2,502
J. O'Leary	2,995	T. C. M. Young	2,500
S. R. Christophers	2,913	H. M. H. Melhuish	2,463
H. R. Dutton	2,873	G. A. Jolly	2,449
W. W. Jendwine	2,820	H. H. Kiddle	2,442
H. M. Brown	2,817	R. F. C. Talbot	2,383
V. B. Nesfield	2,774	F. C. Rogers	2,377
H. Emslie-Smith	2.738	R. D. Saigal	2,366
A. F. Pilkington	2,738	G. F. Humphreys	2,356
H. C. Brown	2,645	M. Ba-Ket	2,332
C. E. Bulteel	2,611	C. A. F. Hingston	2,289
G. H. L. Whale	2,584	C. L. Dunn	2,251
F. P. Vieyra	2,542	A. K. Lauddie	2,228

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REFRACTORY SCIATICA.

X.Z.—Sciatica is known to be extremely refractory to treatment. Among the methods which appear to have been successful in affording more or less durable relief are: - Stypage, *e g.*, the application of extreme cold by means of a jet of ethyl chloride along the course of the nerve, and the subcutaneous injection of atropine. Dissolve 1.50 gr. of the alkaloidal salt in 100 minims of water; three minims of this solution is injected into the affected limb. If the toxic symptoms, &c., subside in less than twelve hours the dose has been insufficient, it being desirable that the stupor, &c., should last twenty-four hours. Dr. Felt, of Boston, claims to have obtained permanent relief in twenty-two out of twenty-eight cases of severe sciatica.

DENTAL PROVERBS.

"A twist in time saves nine." "Abscess makes the gum grow tender." "A tooth in the head is worth two on a plate."—*Judy.*

Dr. Chevers.—Acoin is one of the many substitutes for cocaine, and is especially recommended for use in dental practice on the ground that it is also a strong antiseptic. It is employed in a solution containing 1.10 grain per cent. with 1 per cent. of sodium chloride.

SENATOR HOAR'S JEST.

Senator Hoar received word the other day that a friend who had been supposed to have appendicitis was suffering not from the ailment, but from acute indigestion. "That is good news," said the Senator, "I rejoice that the trouble lies in the table of contents rather than in the appendix."—*Chicago Journal.*

M. R. F.—The common house fly (*musca domestica*) does not bite or sting. When rain is imminent other species enter houses, the stable fly (*stomoxys calcitrans*), for instance, and attack the inmates. Hence the saying that "flies bite before a rain."

OINTMENT IN BLEPHARITIS.

Dr. Raimondo Ferro recommends the following ointment, which has been of great service to him in the treatment of blepharitis:

Take Cupri sulphatis |
Ichthyol. āā .... gr. viij. | 50 ;
Vaselini albi .... oz. j 30 |

M. Sig.: Cleanse the parts and apply locally.

Its use, according to the author, does not affect the cornea or conjunctiva, and so uniform are the results that he considers the ointment a specific in blepharitis. The ichthyol acts as an antiseptic and a stimulant while the copper sulphate exerts astringent properties, reducing the congested sebaceous glands of the eyelids.

Appointments.

Collie, R. J., M.D. (1) Medical Examiner to the London County Council; (2) Assistant Medical Officer to the London School Board.

D'Ewart, John, M.R.C.S., L.R.C.P., House Physician to the Manchester Royal Infirmary.

Ewart, David, M.B., Ch.B.Edin., F.R.C.S.E., Honorary Surgeon to West Sussex, East Hampshire, and Chichester General Infirmary.

French, G. W. H., F.R.C.S., Assistant Surgeon to St. Paul's Hospital for Skin and Genito-Urinary Diseases, Red Lion Square, W.C.

McGachen, F. W. D., M.D., D.Ph.Lond., Medical Officer to the Weymouth and Westham District and Public Vaccinator for Weymouth and Melcombe Regis, *vice* E. N. Pridmore, M.B., Lond., resigned.

Rawdon, F. R., M.B., Ch.B., House Surgeon to the Rotherham Hospital and Dispensary.

Smith, Ward, M.B., Ch.B.Edin., F.R.C.S.E., Surgeon to Sir Titus Salt's Hospital, Shipley.

Valentine, W. A., M.D., B.Ch.Dub., Honorary Surgeon to the Bideford and District Dispensary and Infirmary.

Walker, J. W. Thomson, M.B., C.M.Edin., F.R.C.S.E., Assistant Surgeon to the North-West London Hospital.

Walker, T., M.R.C.S., L.R.C.P., House Surgeon to the Manchester Royal Infirmary.

Wharton, John, B.A., B.C.Camb., House Surgeon to the Manchester Royal Eye Hospital.

Vacancies.

Burton-on-Trent Infirmary.—House Surgeon. Salary £120, together with furnished rooms in the Infirmary, board, coal, and light free. Applications to the Honorary Secretary, Mr. Thomas B. Lowe, J.P., the Infirmary, Burton-on-Trent.

Cancer Hospital, London.—Pathologist. Salary £250 per annum. Applications to the Secretary at the Hospital, Fulham Road, S.W.

Cardiff Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, washing, and furnished apartments. Applications to Leonard D. Rea, Secretary and General Superintendent.

Cheltenham General Hospital.—Assistant House Surgeon. Salary £112 per annum, with board, lodging, and washing. Applications to the Honorary Secretary and Treasurer, General Hospital, Cheltenham.

City of London Epileptic Colony, Horton, Epsom, Surrey.—Medical Superintendent. Salary £600 per annum, with unfurnished house (rates, taxes, and water supply free). Applications to R. W. Partridge, London Asylums Committee Office, 6, Waterloo Place, S.W. (See advt.)

County Mayo Infirmary.—House Surgeon and Compounder. Salary £109 per annum, with apartments, &c. Applications to Dr. O'Malley Knott, Mayo Infirmary, Castlebar. (See advt.)

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100, with board, residence, and washing. Applications to W. Vaughan Jones, Secretary.

Kinsale Union. - Trained Nurse. Salary £60 per annum, with furnished apartments, &c. Applications to John Murphy, Clerk of Union. (See advt.)

London County Asylum, Horton, near Epsom, Surrey.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to R. W. Partridge, Asylums Committee Office, 6, Waterloo Place, S.W. (See advt.)

Middlesex Hospital, W.—Medical Officer. Salary £150 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £120 per annum, with board, rooms, and washing. Applications to the Medical Superintendent.

Wonford House Hospital for the Insane, Exeter.—Assistant Medical Officer. Salary £150 per annum, with full board, &c. Applications to the Medical Superintendent.

Births.

Knaggs.—On Aug. 29th, at 189, Camden Road, N.W., the wife of Dr. H. V. Knaggs, of a daughter.

Lodge.—On Aug. 27th, the wife of Percy Lodge, F.R.C.S., Lee House, Bradford, of a daughter.

Marriage.

Elliston—Warner.—On Aug. 30th, at St. Mary's Parish Church, Wanstead, Essex, Guy, third son of William Alfred Elliston, M.D., J.P., Stoke Hall, Ipswich, to Clara Jane, younger daughter of Benjamin Warner, St. Heliers, Snaresbrook, Essex.

Deaths.

Adcock.—On Aug. 24th, Catherine Elizabeth, widow of Christopher Adcock, M.R.C.S., late of Hunstanton.

Chesman.—On Aug. 28th, at 35, St. Mary's, York, in her 86th year, Sarah, widow of Thomas Cheesman, F.R.C.S.E., late of Sheffield.

Grimsdale.—On Aug. 29th, at his residence, Sandycroft, Hoylake, in his 80th year, Thomas Frederic Grimsdale, L.R.C.P., M.R.C.S.

Willmore.—On Aug. 25th, at Colwyn Bay, Frederic William Willmore, M.R.C.S., of Fairholm, Walsall.

Wright.—On Aug. 27th, at Bedford, Lieut.-Colonel Robert Temple Wright, M.D., I.M.S. (retired), aged 59. No flowers, by request.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—St. George's, 2 p.m.—St. Mary's, 2.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m.—Chelsea, 2 p.m.—Samaritan (Gynæcological, by Physicians), 2 p.m.—Soho Square, 2 p.m.—Royal Orthopædic, 2 p.m.—City Orthopædic, 4 p.m.—Gt. Northern Central, 2.30 p.m.—West London, 2.30 p.m.—London Throat, 9.30 a.m.—Royal Free, 2 p.m

TUESDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—Guy's, 1.30 p.m.—Middlesex, 1.30 p.m.—Westminster, 2 p.m.—West London, 2.30 p.m.—University College, 2 p.m.—St. George's, 1 p.m.—St. Mary's, 1 p.m.—St. Mark's, 2.30 p.m.—Cancer, 2 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—Royal Ear, 3 p.m.—Samaritan 9.30 a.m. and 2.30 p.m.—Throat (Golden Square), 9.30 a.m.—Soho Square, 2 p.m.

WEDNESDAYS.—St. Bartholomew's, 1.30 p.m.—University College, 2 p.m.—Royal Free, 2 p.m.—Middlesex, 1.30 p.m.—Charing Cross, 3 p.m.—St. Thomas's, 2 p.m.—London, 2 p.m.—King's College, 2 p.m.—St. George's, (Ophthalmic) 1 p.m.—St. Mary's, 2 p.m.—National Orthopædic, 10 a.m.—St. Peter's, 2 p.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Gt. Ormond St., 9.30 a.m.—Gt. Northern Central, 2.30 p.m.—Westminster, 2 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—Cancer, 2 p.m.—Throat (Golden Square) 9.30 p.m.

THURSDAYS.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—University College, 2 p.m.—Charing Cross, 3 p.m.—St. George's, 1 p.m.—London, 2 p.m.—King's College, 2 p.m.—Middlesex, 1.30 p.m.—St. Mary's, 2.30 p.m.—Soho Square, 2 p.m.—North-West London, 2 p.m.—Chelsea, 2 p.m.—Gt. Northern Central (Gynæcological), 2.30 p.m.—Metropolitan, 2.30 p.m.—London Throat, 9.30 a.m.—St. Mark's, 2 p.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Throat (Golden Square) 9.30 a.m.

FRIDAYS.—London, 2 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 3.30 p.m.—Guy's, 1.30 p.m.—Middlesex, 1.30 p.m.—Charing Cross, 3 p.m.—St. George's, 1 p.m.—King's College, 2 p.m.—St. Mary's, 2 p.m.—Ophthalmic, 10 a.m.—Cancer, 2 p.m.—Chelsea, 2 p.m.—Gt. Northern Central, 2.30 p.m.—West London, 2.30 p.m.—London Throat, 9.30 a.m.—Samaritan, 9.30 a.m. and 2.30 p.m.—Throat (Golden Square), 9.30 a.m.—City Orthopædic, 2.30 p.m.—Soho Square, 2 p.m.

SATURDAYS.—Royal Free, 9 a.m.—London, 2 p.m.—Middlesex, 1.30 p.m.—St. Thomas's, 2 p.m.—University College, 9.15 a.m.—Charing Cross, 2 p.m.—St. George's, 1 p.m.—St. Mary's 10 p.m—Throat (Golden Square), 9.30 a.m.

At the Royal Eye Hospital (2 p.m.), the Royal London Ophthalmic (10 a.m.), the Royal Westminster Ophthalmic (1.30 pm.), and the Central London Ophthalmic Hospitals operations are performed daily.

PUERPERAL ECLAMPSIA
IN THE
LIGHT OF THYROID INADEQUACY
AND ITS
TREATMENT BY THYROID EXTRACT. (a)

By H. OLIPHANT NICHOLSON, M.D.,
M.R.C.P.ED.,
Obstetric Physician to the New Town Dispensary, Edinburgh.

IN the whole range of obstetrics the subject of puerperal eclampsia is the most important problem yet awaiting solution. It is now generally believed that the convulsions are due to an acute toxic poisoning, but how the toxins arise and the precise manner in which they produce their effects, are questions at present unanswered.

In observing pregnant women during the later months of pregnancy are there sufficiently definite clinical signs which will enable us to pick out those who are likely to become eclamptic? I believe trustworthy information on this point is afforded by a study of the circulatory phenomena during pregnancy, and, if the state of the urinary secretion be also considered, it is always possible to separate the abnormal cases from the normal. When a pregnant woman threatens to become eclamptic there are some significant features to be noted.

(1) The characters of the pulse become strikingly altered from those of normal pregnancy—the sphygmographic features are those invariably associated with increased peripheral resistance (vaso-constriction). (2) The walls of the radial arteries become contracted (diminished radial calibre). (3) There is a pronounced and permanent rise in the arterial blood pressure, which increases still more as convulsions become imminent. (4) There is a marked diminution in the quantity of urine secreted in the twenty-four hours. (5) The quantity of urea excreted in the urine is much diminished.

The diminished urea excretion is, perhaps, the most striking and important matter for consideration, for it points to some disturbance in the process of nitrogenous metabolism. It is a well-established fact that the active thyroid supplies a secretion which is essential to the maintenance of the normal metabolic cycle, and with the occurrence of pregnancy the gland undergoes constant enlargement to meet the needs of the increased metabolism at this time. A larger supply of iodothyrin is needed in the pregnant than in the non-pregnant state. In all conditions of hypothyroidism—myxœdema, cretinism, &c.—the urea excretion is diminished, and the quantity of urine secreted is also lessened. The circulatory features in advanced myxœdema are the same as those of the pre-eclamptic state, and the peculiar solid œdema and albuminuria may be common to both conditions.

With such a train of symptoms—whether they occur in a myxœdemic or in an eclamptic patient—the action of thyroid extract is a very precise one. Under its action the metabolic processes of the body are greatly stimulated, and there is a striking increase in the excretion of urea. This at once brings the urine of the eclamptic nearer to the normal again, and coincidently the abnormal conditions of the circulation are altered; the arterial calibre becomes uniformly enlarged, and the secretion of urine is very greatly increased. The diuresis is accompanied by a disappearance of the œdema and albuminuria.

In a general way my conception of the nature of puerperal eclampsia is this: In some pregnant women—for reasons which are at present obscure—the supply of iodothyrin in the tissues becomes, gradually or suddenly, insufficient for the needs of normal metabolism. Then certain toxic substances, which may be intermediate or imperfectly converted products of nitrogenous metabolism, enter the blood. These toxic substances cause contraction of the arteries, not only of the body generally, but of the kidneys in particular, and ultimately, the flow of blood through the kidney being prevented, suppression of urine occurs. Then, as in ordinary uræmia, convulsions are produced. The toxins of eclampsia act like toxic doses of digitalis, and eventually stop their own excretion by producing intense contraction of the renal vessels.

On this view of eclampsia two main principles of treatment are clearly indicated. (1) Re-adjustment of the processes of metabolism, so as to favour the complete metabolism of nitrogenous substances. (2) Re-establishment of the secretion of urine.

Thyroid extract, by its well-known influence on proteid metabolism, fulfils the first indication admirably. The second indication is equally well fulfilled by this remedy, because in order to make the kidney secrete again, the all-important thing is to relax the spasm of the renal arteries. Nothing else will lead to a re-establishment of diuresis, and all the successful remedies used in the treatment of eclampsia—*large* doses of morphia, saline infusions, &c.—really act in this manner. Oliver has shown that thyroid extract possesses a specific action in enlarging the calibre of the arteries, and no remedy acts so profoundly or permanently as a vaso-dilator. I have already shown that when this drug is administered to eclamptic patients in sufficient doses to produce symptoms of "thyroidism," the re-establishment of the secretion of urine is secured, and the other untoward symptoms disappear.

In support of my view that the toxins of eclampsia act as powerful vaso-constrictors, and more especially on the renal vessels, thus leading to suppression of urine, I may mention the following facts :—1. In eclamptic pregnant women the radial arteries become contracted, and the peripheral resistance steadily increases as convulsions become imminent. 2. The blood pressure becomes permanently raised in the pre-eclamptic state. 3. When the blood pressure is at its highest and the radial arteries are most contracted, the secretion of urine is at its lowest point. 4. On the re-establishment of diuresis there is an enlargement of the radial calibre, and a more or less marked fall in the blood pressure.

(a) Abstract of paper read in the Section of Obstetrics, British Medical Association Meeting, Manchester, August, 1902.

As regards treatment, thyroid extract may be used in all cases of eclampsia; but when convulsions are frequent and severe, at least one *large* dose of morphia should be given. Thyroid extract is of great value as a prophylactic remedy, to readjust the process of metabolism when the first indications of breakdown appear. One does not wait for albuminuria; if there is marked *diminution in the quantity of urine*, œdema, headache, and *vomiting*, we should immediately put the patient on five grains of the extract twice a day. Rest and non-nitrogenous diet may also be ordered for a few days until the ominous symptoms subside. In a day or two the secretion of urine becomes greatly increased, and the metabolic processes are again going on efficiently.

Should the symptoms have developed up to the stage of suppression of urine, and if convulsions have occurred, the main object of the remedy is to re-establish renal activity. It must then be sufficiently pushed to produce its full effects upon the circulation. It is necessary to produce symptoms of "thyroidism" as rapidly as possible, for then we know that the arterioles are fully relaxed. Ten or fifteen grains of the dry extract may be given by the mouth and repeated every hour if necessary; or, if the patient cannot swallow, similar doses of the liquor thyroidei must be injected hypodermically. In eclamptic patients, as in cretins, symptoms of "thyroidism" are sometimes very readily induced.

In conclusion, I would like to direct attention to the possible value of thyroid extract in some of those rare cases of suppression of urine occurring after labour or miscarriage.

THE TREATMENT OF ABDOMINAL WOUNDS IN WAR. (*a*)

By CHARLES ROBERTS, M.B., B.S., F.R.C.S.,

Resident Surgical Officer, Manchester Royal Infirmary; late Civil Surgeon, South African Field Force.

In discussing the treatment of abdominal wounds we have to consider (1) the nature of the injury; (2) the cases in which operative interference is indicated; and (3) to what extent the prospect of success of abdominal operations is diminished by the difficulties inseparable from campaigning. When the wound is caused by a high velocity and mantled bullet of small calibre, as the Mauser and Lee-Metford, the extent of the visceral injury depends little, if at all, upon the range at which the bullet is fired, except in some instances in which the wound is complicated by injury to bone.

At very long ranges when the force is spent and in ricochet wounds the bullet may be retained. The course it takes within the abdomen is then lost and the internal injuries may be widespread and with difficulty made out. When both wounds of entry and exit are present the track is always that of a straight line between these two points, and from anatomical knowledge we are able to say what viscera may have been injured. Transverse wounds are more fatal than those passing in an antero-posterior direction. Wounds above the umbilicus are more favourable than those below. Direct antero-posterior wounds in the small intestine area are very unfavourable. Complete transverse wounds above the umbilicus are very unfavourable. That the small intestine area may be crossed without perforation occurring has been demonstrated:—

1. By examination after death. In the published record of the work of the Portland Hospital in South Africa, written by the professional staff, a case is described the details of which were supplied by Mr. Cheatle.

Two perforations were found in the cæcum and sigmoid flexure of the colon, and, though the bullet had undoubtedly crossed the area occupied by the small intestine, no wound of the bowel had occurred.

2. By examination during laparotomy. Mr. Makins, in his work on his surgical experiences in South Africa, gives an account of an operation in which two linear rents were found in the jejunum involving the peritoneal and muscular coats only. He also noted in other instances linear ecchymoses and wounds of the peritoneal and muscular coats alone, associated with complete perforations. The view that the intestine escapes perforation in many of the cases that recover is supported by the fact that frequently so few abdominal symptoms are present. It is difficult to believe, however, that in all cases no perforation is present, for in many cases shock is severe, frequent vomiting persists for two or three days, the temperature rises, and the abdomen becomes rigid and painful, these symptoms being readily attributable to the shock of perforation and slight local peritoneal infection. The post-mortem examination in Mr. Cheatle's case, previously mentioned, showed that no extravasation of fæces had occurred from a perforation of the cæcum, and in cases operated on no free escape of fæces has been found before manipulation. Sometimes the presence of melæna has formed strong evidence of perforation. There is little doubt that a perforation may heal primarily or become shut off by adhesion to a neighbouring coil within a few hours.

In considering the cases in which operation is required we must first exclude those wounded who will die in the first twenty-four hours from intra-peritoneal hæmorrhage or from the shock of extensive internal injuries and who are not amenable to surgical treatment. Their number is always considerable, probably from 20 per cent. to 30 per cent. of those wounded.

Where increasing intra-peritoneal hæmorrhage is threatening life, and the surroundings and general condition of the patient allow of it, laparotomy must always be performed and the bleeding arrested, whether from torn vessels in the omentum or mesentery or from laceration of the liver or spleen. Only too often, however, extensive visceral injuries will also be found, and a favourable result will not be obtained. Wounds of the liver, kidney, and spleen as a rule heal well, and when hæmorrhage is not dangerous require no operative treatment except for secondary complications such as biliary fistula, hydronephrosis or perinephritic abscess. Laparotomy may be required when perforation of the stomach or bowel may have taken place. If we exclude those who die in the first twenty-four hours we may estimate that, of the cases of penetrating abdominal wounds amenable to surgical treatment, about 60 per cent. will recover. The recoveries, however, are chiefly among those cases in which the area of the small intestine is not crossed, and when this area is involved the mortality is probably very great. Too often without exploration we cannot be sure whether perforation exists or not, and whilst a routine laparotomy is not justifiable in every case, it should

---

(*a*) Abstract of paper read before the British Medical Association, Manchester, July-August, 1902.

be performed at the first evidence that perforation exists. Such evidence may be found in the persistence of shock, a steady increase in the rate of the pulse, and in the abdomen becoming increasingly rigid and tender, and especially is it probable if vomiting has persisted and the passage of flatus is arrested. Under these circumstances, and when the surroundings are such as not to expose the patient to fresh dangers, the operation should not be delayed, and the apertures may be dealt with by suturing, or the area of the wound may be resected according to the condition found. Especially is the operation likely to prove successful when the injury is localised, the patient is seen within six hours of being wounded, and transport has not been difficult. When the bullet is retained, or the track is a complete transverse one, the prognosis is far less favourable. The results of laparotomy for gunshot wounds in war have been most unfavourable.

In the Spanish-American war Senn reported that all cases he knew of that were operated on died. In the Tirah campaign, of eight cases of penetrating wounds of the abdomen, five were operated on and all died. In the Boer war I only knew of two successful operations performed for wounds of the small intestine. In the American war in the Philippines Dr. Robinson reported that five cases were operated on and four died. The unfavourable results are attributable to various causes. The severity of the injuries, the delay in bringing in the wounded, difficult transport and the unfavourable surroundings, render abdominal operations at the front in most cases unpermissible. We are led to the following conclusions:—

1. That, as a rule, the conditions in a field hospital are not suitable for performing laparotomy. Moreover, many patients with penetrating abdominal wounds recover without operation, and in the case only of those who die the nature of the injury is such that death must result whatever be the conditions of operation, and an exploratory laparotomy may add a fresh danger to the patient.

2. When occasions arise in which the conditions of operation approximate to those in civil practice, laparotomy should be undertaken for intraperitoneal hæmorrhage endangering life, and when there is evidence that perforation of the stomach or bowel probably exists, provided that the patient is seen early enough.

CARBON MONOXIDE POISONING.

By T. O'CONNELL REDMOND, F.R.C.S.I.,

AND

JAMES C. McWALTER, M.A., D.P.H. (a)

In March of this year the Legislature requested the Massachusetts State Bureau of Health to give particulars as to the number of deaths from carbon monoxide poisoning, both before and after the introduction of water gas into the illuminating gas generally used.

The reply states:—

In the thirteen years previous to the introduction of water gas in Massachusetts (1876-88) the number of deaths registered as being due to poisoning from carbon monoxide in illuminating gas was eight.

In the thirteen years following the introduction of water gas into the illuminating gas the number of deaths registered due to illuminating gas poisoning (carbon monoxide) was 459.

Again, in Boston the proportion of carbon monoxide in the illuminating gas was exceptionally high in 1898 and 1899, and the number of deaths was 109, but as a result of agitation the proportion was reduced to nearly half in 1900 and 1901, and the number of deaths fell to thirty-nine.

We feel that an apology is perhaps due to the Association for quoting American statistics rather than British, but the latter are not available except in cases where deaths take place from carbon monoxide poisoning in factories. In these cases a recent order requires that his Majesty's Inspector of Factories shall hold a special inquiry. Dr. Whitelegge has already done some excellent work in this line, but as his official reports are available it is unnecessary to quote them. What seems really amazing is, that when the use of water gas as an illuminant is so fearfully fatal to life, as is fully proved by the above figures, the public health authorities should have absolutely no power to control its use, or even to specify the proportion which may be used by gas companies, whose only desire naturally is to supply an illuminant at little cost to themselves. This is all the more surprising when cases of carbon monoxide poisoning have already been made the subject of special legislation under the Factories Act. Surely the general public have a right to some protection against the indiscriminate poisoning by this gas, if the fact of being a worker in a factory entitles one to a special inquiry where it is suspected.

Water gas is supplied by the gas companies merely on account of the ease and cheapness of its preparation. It is made by passing steam over heated coke, and adding to the product the gas derived from petroleum or resin oil. This is mixed with the ordinary gas derived from the distillation of coke in proportions which merely depend on the fancy of the companies supplying the article, as there is no legislation to compel them to confine its use to any limit. Of course ordinary coal gas contains carbon monoxide in varying proportions, perhaps 6 to 8 per cent., and its poisonous properties are almost entirely due to it. Water gas, on the other hand, contains about 40 per cent. of carbon monoxide, and is many times more poisonous.

The peculiar pinkish tint of the body, the cherry redness of the blood, the changes in the hæmoglobin, the extreme congestion of the capillary vessels brought about by the general vascular paresis, the fulness of blood in the viscera, the remarkable resistance to putrefaction, the rose-red colouration often met with in the internal organs, in the muscles and in the serous membranes—all constitute a post-mortem picture not likely to lead one astray when there is a history of the probable cause. What we are rather concerned to investigate is the group of symptoms likely to be presented in those cases where there is a slow poisoning or intoxication with the gas, such as is now likely to occur in every city and in any house where the pipes happen to be leaky, or where operations in the gas mains are proceeding in the immediate vicinity. The literature on carbon monoxide intoxication is very scanty, and as the published accounts do not quite agree with our experience of the affection, we bring forward a few notes on the subject, with a view to stimulating discussion and observation rather than with any hope of adding to existing knowledge.

It is generally agreed that the first subjective symptom which comes on after breathing the poison is a burning feeling in the skin of the face, followed by giddiness and headache; the headache gradually growing more intense and the giddiness more marked: and, as Dr. Klebs has pointed out, its chief site is across the forehead. This is generally associated with a subjective feeling of strong pulsation in the temporal arteries. After this stage a feeling of intense anxiety and oppression, referred to the præcordial region, is generally observed, frequently followed and partly relieved by a sensation of nausea. Now come on a variety of subjective sensations which vary in every individual, as noises in the ears, motes dancing about *(muscæ volitantes)*, and occasionally feelings of exultation and excitement. It is mainly at this stage that the experiences of observers differ so much. According to our observations, persons in whom alcoholism is a usual occurrence are inclined to regard the sensations occurring at this stage as quite similar to those they have been accustomed to when indulging in their accustomed potations, and hence they regard them as rather pleasurable and desirable. Carbon monoxide does, indeed, produce a true intoxication, and hence it happens that its victims rather yield to its influence than fly for relief.

(a) Being a paper read at the Annual Meeting of the British Medical Association, Manchester, July-August, 1902.

This characteristic was well exemplified in a case brought in to us the other day. A Corporation labourer had been working in the street, over a broken gas main, and gradually develcped the symptoms of carbon monoxide intoxication. Instead of seeking a remedy, he persisted at the work—ripping up the road, of which every spade full was saturated with the gas. Suddenly he fell prostrate, and apparently lifeless. He was carried into the surgery and was found to be absolutely unconscious, although presenting none of that pallor usually associated with such a case. The pulse was good and the heart beat strong, but respiration was almost imperceptible, although the patient was a vigorous, well-built, broad-chested young man of the labouring class. The mucous membranes were of a lively red, and the diameter of the pupil scarcely affected. The jaws were clenched, and when ammonia was administered, the act of deglutition was performed with difficulty, the voluntary portions of the tract being almost completely paralysed; strong irritants applied to the nape of the neck produced scarcely any reaction, and except for the heat and the heart beat, all the appearances of death were present. Artificial respiration being vigorously kept up for about twenty minutes, the patient suddenly recovered. No sooner had consciousness completely returned than he assumed the bellicose attitude of one recovering from a drunken sleep, defied us to retain him, and refused to proceed to hospital in the ambulance which had been provided for him. As he was obviously still under the effects of the narcotic the police were requested to convey him for safety to the hospital, but he resisted their efforts and returned to his work, where in about ten minutes he collapsed again.

It has been asserted that the psychical condition which precedes the loss of consciousness is often a distress of mind full of agonising tortures, and less often a sort of pleasant or ecstatic feeling. So far as our observations have extended the latter is the more dangerous and the more common occurrence. Suicide by charcoal burning could surely not be so popular in France if the preliminary intoxication were otherwise than agreeable, and those cases of carbon monoxide poisoning which now occur so frequently, and in which the victim might have saved himself had he rushed to the door or the window, are unintelligible if we are to assume that any period of agonising torture preceded the final insensibility.

The class of cases in which the physician has to be most on his guard against the possibility of the air of the dwelling-house being contaminated with carbon monoxide is that of pulmonary diseases. The gravity of such an occurrence lies in the fact that the gas acting as a sort of anæsthetic on the mucous membranes of the bronchial tubes sometimes even checks the cough, and the patient, believing that he is rather improving, is content to lie in a lethargic and comatose condition in bed, unable to make any exertion, disinclined to get up, and losing all appetite until finally he is so exhausted that it becomes impossible to rally him. Such a condition was well marked in the case of a young married woman who kept a boarding-house in Dublin; she contracted a slight attack of bronchial catarrh, and was directed to remain in bed and submit to the ordinary treatment. After a week or so the cough disappeared, but she complained of great lassitude and anorexia. No definite sign of phthisis could be elicited, and there appeared nothing to account for the extreme debility, so the patient was ordered to the sea coast. Instead of going she sought one excuse after another for putting it off, and preferred to lie in bed, indifferent and careless to everything, but complaining of no pain. The appetite failed absolutely, and in a couple of weeks she died, apparently through sheer exhaustion. About a week after her death her sister, a strong, bright, buxom country girl, took a slight cold, and going to bed rapidly exhibited the same symptoms of apathy, anorexia and lethargy, becoming perfectly indifferent to every consideration of life or death. Careful search having been made for any possible cause for such a condition or any likely source for carbon monoxide, it was found that although there was no gas jet in the room, yet in a chamber underneath a gas stove used for cooking was leaking, and had been so for some considerable time. When this was remedied the patient rapidly got better.

One can only suppose that the great difference to be noted in attacks of poisoning—when in some cases the access of insensibility is sudden and consciousness is withdrawn, as by a stroke; and in others is preceded by phenomena indicative of great discomfort, anxiety, nausea, discomfort, præcordial distress—must be due to the proportion of carbon monoxide compared with that of fresh air. Thus in very badly ventilated rooms the ordinary symptoms of asphyxiation are added to those of intoxication, and the patient makes an effort to leave the poisonous atmosphere, or tries to get air by opening the window, &c., whilst the former phenomena are disclosed when the gas is inhaled in much greater volumes but in the open air. It has often been noted that insensibility attacks persons just as they are making to the door or window, when they fall down and lie unconscious. At this stage all perception of anything further is lost, and the victims can give no further account of themselves. In those cases which recover the subjective symptoms are very varied. Most usually there is a marked feeling of weakness and fatigue, lasting for several days and accurately corresponding to the objective symptoms of this stage. A certain dulness of intellect, a want of clear conceptions, vague headaches and general obscurity of the mental faculties are usually to be observed. In extreme cases the poison gives rise to profound functional mischief in the spinal cord, and then disorders of cutaneous sensibility and flying pains in the extremities are especially marked. In fatal cases the victim either never awakes from the deep coma, or he exhibits only transitory and imperfect returns to consciousness which again give place to fresh attacks of insensibility and more or less suddenly lead to death. The objective phenomena are numerous and varied. Thus the external surface of the skin shows much congestion and redness at an early stage, more markedly in the face; the ocular conjunctivæ is often affected, but the pupil may not be much contracted. The mucous membranes which can be seen keep for a long time their reddish tint. In the later connection the skin may become pink, but only towards the end does it exhibit any cyanosis, or livid hue, and then only in consequence of the disordered circulation. Some observers have noted many of the sequelæ of toxæmia such as are common to all such cases, including a variety of cutaneous affections, from a simple rose rash or the appearance of vesicles to extensive gangrene or symptoms which evidently depend on a vasomotor lesion.

Lendet described herpes labialis and herpes zoster as a consequence of carbon monoxide poisoning. Although the respiratory functions are not always very prominently affected it is far more general for the initial stages of dyspnœa to be succeeded by a comatose condition, when death may occur without marked convulsions. As a rule, however, convulsions do occur in the final stage of the poisoning. Pathological changes in the organs of respiration, such as acute bronchitis, pleurisy, pneumonia, or hæmoptysis, are not uncommon. Klebs considered such complications to be accidental, and due to the presence of other irritants, whilst Friedburg believed them to be directly dependent on the carbon monoxide. They are probably due mostly to the disordered condition brought about by the narcotic poisoning, and partly to the irritating action of the mixed gases on the bronchial tubes.

The arterial pulse is at first full and quickened, but later on becomes gradually less powerful, and in the fatal stage of course can scarcely be felt. The temperature of the body is usually decreased, perhaps as much as four or five degrees. As regards disorders of the digestive organs vomiting seems rather common in chronic cases of poisoning, and Ziemssen and Thomson have described extensive inflammation of the mucous membrane of the digestive tract, with a tendency to necrotic ulceration. Diabetes and albuminuria may both occur, but are usually transitory.

The disorders of the nervous system are sometimes local and sometimes general. Paralysis of the voluntary muscles may take place, and is often followed by atrophy of the muscles concerned. Anæsthesia of the cutaneous surfaces is not uncommon, and paralysis of the involuntary muscles of the bowels and bladder have been recorded.

The duration and the intensity of the action of the poison must, of course, determine the result in persons exposed to the inhalation of carbon monoxide. Fatal cases occur chiefly at night when help is not at hand, and that intervention, which, if timely, might have saved life, comes some hours after unconsciousness has set in. If the poisoned person be more or less quickly removed from the injurious vapours, recovery often takes place rapidly, but, when the injurious symptoms persist, death may occur in a day or two, in spite of all remedial measures.

As regards antidotal measures we have nothing very new to suggest. Artificial respiration, kept up by relays of volunteers, with ammonia and stimulants internally, and ammonia to the nose and spine, have proved successful in our hands. When, in spite of these efforts, the threatening symptoms persist, Traube and others recommend depletory transfusion of blood; that is, the poisoned blood is first removed, and a corresponding portion of the normal blood of a healthy man is substituted by ordinary methods of transfusion.

These remarks are, after all, the mere commonplace of the subject of carbon monoxide poisoning, but what we wish to press on the earnest attention of the State Medicine Section is that public health authorities have absolutely no power to deal with the quality of the gas supplied by the gas companies. They may be merciful and give us a coal gas containing 8 or 10 per cent. of carbon monoxide, or they may mix it with as much water gas as will bring the proportion up to the 30 or 40 per cent., but the medical officer of health or the local sanitary authority has absolutely no power in the matter.

Again, those gas pipes which were impermeable to ordinary gas may leak with a change in the composition of the gas, and hence in its pressure and gravity is made by the lighting company. Then the deadly gas, finding its way into the sick room, may determine the death of many a patient suffering from pulmonary or cardiac disease, and yet we are powerless to prevent it, at least until we so study the subject that we shall be able to satisfy the legislature of the need of controlling the proportion of poison in the illuminant with which any company may supply the public.

Before leaving the subject we may be permitted to refer to a very fruitful source of carbon monoxide poisoning, namely, that caused by the saturation of the soil from leaking gas mains, and the periodic exhalation of the gas, either when the ground is turned up in the process of road repairing, bursts of gas in water pipes, excavations, &c., or its liberation on account of variations of temperature on the surface, or the changing bed of the ground water.

Pettenhoffer, as is well known, demonstrated that the incidence of enteric fever in Munich depended on the varying level of the ground water, and Sir Charles Cameron explains the prevalence of this disease in Dublin by saying that it is a water-logged city, reposing on a bed of ground water of varying, but always slight, depth.

It appears to us that the notoriously high death-rate of Dublin needs some other explanation than this, especially as it remains abnormally great even when the zymotic death-rate is well below the average.

Now it would seem that of all the lighting gas produced in the Dublin gas works 10 per cent. is absolutely lost before it reaches the consumers' meter. The company naturally take no interest in its fate after it has left that interesting recorder, but as they presumably do everything possible to check the wastage on their side of the meter, and are apparently unable to reduce it below ten per cent., it may fairly be assumed that another ten per cent. is lost between the meter and the consumers' burners. As regards those thousands of cubic feet which disappear every day in the gas company's side of the meter, what becomes of it is rather a mystery. For our part we believe that it saturates the soil, and is evolved therefrom with results that are very frequently fatal though apparently often unperceived. The following case seems to prove this—at least one of us was able to persuade the coroner that the fatality was due to carbon monoxide :—

In November, 1901, the inhabitants of a middle-class house on the north side of Dublin—a man and his wife, noticed a somewhat peculiar, but not unpleasant smell through the house. It never struck them as being the smell of gas, nor was it suggestive of bad drainage, yet they felt queer, powerless and dazed, and both of them lost their appetites. Husband and wife were attacked similarly, and they experienced an intense thirst, consuming large quantities of lemonade. At night they shut the door as usual and went to bed. In the morning the man was so weak that he could scarcely get out of bed, but he managed to dress and go downstairs. His wife had a headache, she could not rest, her heart was leaping, and she was very weak; there were other inhabitants in the house also affected, and though nobody seemed to suspect the source of the smell they were advised to leave the door open. This the owner refused to do, and all retired to bed as usual the following night.

In the morning the neighbours noticed that nobody was stirring about the house. After some time they got uneasy and commenced knocking at the door. Finally a man staggered down to the door, the rest of the dwellers were in bed insensible, and one old man upstairs was dead. The others were brought to hospital and eventually recovered. One of them was three days unconscious. During the night it seems that they had all been quiet, although one of them retched a great deal. A peculiar characteristic which we have alluded to above, was that nobody felt any dread of the smell; they could not be got to believe that it was gas. The man who had been unconscious for three days states that his only strong feeling was "to throw himself down anywhere at all," and that he finally lost all memory and felt as if in a trance. This man ought to have been almost immune to gas poisoning, as he was an engineer working a gas engine at Broadstone Factory. He never experienced the slightest inconvenience at it, although the fitter whose duty it was to overhaul the engine occasionally would frequently complain of the nausea and discomfort which it brought on.

This case, we submit, goes to prove what we have contended for above—namely, that carbon monoxide is a narcotic poison; that it is so far from being disagreeable that no effort is made to escape from its influence; that it is the probable cause of many unexpected deaths which have not been carefully inquired into; and we suggest that legislation is urgently needed to regulate the output of carbon monoxide in burning gas.

THE DIETETIC TREATMENT OF PULMONARY TUBERCULOSIS. (a)

By NOEL D. BARDSWELL, M.D., M.R.C.P.,
Physician to the Sanatorium, Mundesley,
AND
J. E. CHAPMAN, M.R.C.S., L.R.C.P.,
Clinical Pathologist to the Sanatorium, Mundesley.

Before referring to the special factors which influence the diets for consumptives, it is necessary to consider the physiological diet.

A physiological diet for an average man of eleven stone, doing moderate muscular work, may be considered to contain 120 grammes of proteid, 110 of fat, and 365 of carbohydrate, with a calorie value of 3,098. If this same man were "at rest," *e.g.*, doing clerical work, he would require only 2,500 calories Such a diet as the following would be required: Proteid 120, fat 110, carbohydrate 240.

Many people, however, live constantly on smaller diets without showing any obvious signs of under feeding. They live chronically under weight at a low nitrogenous level, and have a lowered resistance to tuberculosis.

Allowances must of course be made for sex, age, weight, work, weather, &c.

We have next to consider the additional factors due to the existence of tuberculosis.

1. The presence of tuberculosis causes increased waste of all tissues, especially of fat. The indication is therefore an increase in all constituents of the physiological diet.

2. The patient may be under normal weight. A sufficient increase in diet, especially as regards fat and carbohydrate, must be made to restore the tissues in addition to meeting the current requirements of the body.

3. Clinical experience and experimental work have shown us that, equivalent for equivalent, proteid has a much greater effect in inducing arrest of tuberculous processes than either fat or carbohydrate. In fact good results have so consistently been obtained on relatively high proteid diets that we now invariably make use of them.

The advantage of a diet rich in proteid and only slightly increased in fats and carbohydrates are as follows:—

(*a*) There is no necessity to prescribe large amounts of fats, starches and sugars, which are all disliked by the consumptive.

(*b*) Proteid can be given in large quantities in liquid form in milk, and milk can be largely fortified by the addition of any of the numerous casein preparations in the market, *e.g.*, plasmon.

(*c*) It is much easier to give proteid in large quantities than either fat or carbohydrate. This is of importance when prescribing a diet of small bulk to patients with atonic dyspepsia and commencing dilatation of the stomach.

(*d*) Weight is put on at a moderate pace only, hence the physiological balance of cardio-respiratory functions and body weight is not upset as when excessive fat weight is gained rapidly.

4. Intestinal absorption, &c. During the past eighteen months we have devoted considerable attention to this subject, and the following conclusions are based upon the results of an extended series of experimental investigation. (*a*) The percentage absorption of proteid is normal on moderate diets, and falls somewhat when very large diets are given, but even then is very rarely below 90 per cent. of the total proteid taken.

The absorption of fats is also normal, and in cases under weight is frequently higher than normal. This absorption remains very high even when very large amounts of fat are taken, *e.g.*, a patient taking 231 grammes of fat absorbed 96 per cent. This good absorption of proteid and fat lasts till death, *e.g.*, 93 and 97 per cent. respectively were absorbed till within three days of death in one case.

Apart from lardaceous disease of the intestine, of which condition we have not yet sufficient data to warrant any definite opinion, in all probability acute diarrhœa alone interferes with absorption.

In short, our researches have shown us that the consumptive, of whatever clinical type, digests and absorbs at least 90 per cent. of proteid and fat of all food he retains, and the probabilities are that he deals equally well with his carbohydrate. It has been a source of interest to note that most pronounced anorexia and dyspepsia coexist with normal absorption, and the gastric analyses in such patients afford evidence of normal secretions.

Although the condition of the stomach secretions give no dietetic indications, the stomach in other respects has an important bearing upon the constitution of the diet since atonic dyspepsia and dilatation are among the most serious complications the sanatorium physician has to guard against.

5. Another factor to be remembered is that patients can be overfed; the good absorption already referred to makes this an easy matter. "The fat, plethoric patient, so breathless that he cannot move across the room without great dyspnœa, probably a stone or more above normal weight, and who has overstepped the capacity of his lungs and heart," is the able description of the overfed consumptive given by Sir Douglas Powell.

Having discussed the chief factors to be considered in determining a diet, we will now describe the actual diets. In practice we use diets yielding from 120 to 160 grammes of proteid daily for men, with a proportionate reduction for women; with regard to fats and carbohydrates we give amounts that we consider sufficient to supply the current demands for energy, and to restore wasted fat at a moderate pace. The following would be such a diet for a man normally eleven stone in weight, about a stone below weight, with but slight disease, slight constitutional disturbance, normal alimentary tract, and walking five miles daily. Proteid 140, fat 140, carbohydrate 270, being an increase of 20 proteid, 30 fat, and 30 carbohydrate on the normal diet for the same man.

(a) Abstract of a Paper read before the Annual Meeting of the British Medical Association, Manchester, August, 1902. Towards the expenses of this research a grant was made by the Scientific Grants Committee of the British Medical Association.

The composition of the diet would be as follows:—

7.30 a.m.—Milk ½ pint.

8.30, Breakfast.—Milk ½ pint, bread or toast 2 ozs., butter ½ oz., 2 ozs. fish or bacon, &c., and an egg.

11 a.m.—Milk ½ pint.

Lunch, 1.30.—Milk ½ pint, bread 2 ozs., butter ½ oz., fish 2 ozs., meat 3 ozs., milk pudding 5 ozs.

Dinner, 7 p.m.—Similar to lunch, but with only 2 ozs. of meat; 10.30, milk ½ pint.

These figures are only approximate, as the actual diet was prescribed in the metric system.

On this diet the patient recovered his lost weight at the rate of two pounds a week, and made an excellent recovery in every respect.

It is of interest to compare this diet with another sanatorium diet which has come under our notice.

Breakfast.—2 pints of milk, bread about 5 ozs., butter 3 ozs., and an omelette containing 3 eggs or an equivalent of other foods.

Lunch.—Milk 2 pints, large plate of curry, roast meat 4 ozs. (about), potatoes 3 or 4 ozs., green vegetables 2 ozs. with melted butter, milk pudding 8 ozs. or more with cream.

Dinner.—Similar to lunch, but with no curry, but with the addition of 5 ozs. bread and 3 ozs. butter. It is almost unnecessary to add that atonic dyspepsia and vomiting was the rule in this institution.

When the existence of atonic dyspepsia renders it necessary to conserve the tone of the stomach, we concentrate the diet by excluding all indigestible articles and those of low nutritive value, such as green vegetables, soups, sauces, &c. If this is insufficient we further concentrate the diet in various ways, a description of which would be too long to include in this paper.

In conclusion, we wish to point out that although overfeeding is frequently associated with very satisfactory progress in the lungs, yet the administration of what is practically only a small increase on the physiological diet is quite sufficient to ensure equally satisfactory improvement in the lung condition with much less risk of injurious consequences, and with the minimum discomfort to the patient.

SOME POINTS IN THE GENERAL MANAGEMENT OF ASYLUMS FOR THE INSANE.

By LOUIS VINTRAS, M.D., B.Sc.,
Physician to the French Hospital.

Few positions require more forethought, tact and power of organisation than that of superintendent to one of the large asylums for the insane, if it be desired to raise the management of such an institution above the mere routine of tradition. There is, at the present day, still too much conservatism, too much running on old lines, in the way in which we treat the insane, and this probably explains in part how it is that we have made comparatively little progress in dealing with this problem, which is ever increasing in magnitude. Of the medical men who, in the early part of their career, take posts as assistant medical officers in asylums, not a few tire of waiting for advancement, and soon drift into other and more immediately lucrative paths of their profession. A few remain, but of these some, by the time they have reached those positions, where they have a freer scope for the exercise of such personal views and influence which should be the result of experience, have lost the freshness of their enthusiasm, and, disappointed by the hopelessness of most of the cases, are content to continue merely the application of such methods as they have been long familiar with, without seeking to introduce any new elements or improvements. Yet it is to the general management of these patients that we must look for any progress in the treatment of the various forms of insanity, for we know from the very nature of the lesions how little we can expect from the exhibition of drugs and other therapeutical agents. It is by striving to reawaken the dormant activity of the diseased cells, wheresoever there is the remotest possibility of doing so, by such natural methods as are at our disposal, that alone we may hope to do good. We must bring ourselves to look less and less on our asylums as places where those whose mental balance has been disturbed are permanently kept out of the way and prevented from doing injury to themselves or their fellow-creatures. That this was, and is still, the primary *raison d'être* of such institutions is nothing that we need feel ashamed of, but this constitutes only one-half of our duty. We must turn our thoughts now to giving to our asylums a wider and more humanitarian meaning, by gradually converting them into sanatoriums. From mere places of safety they must become places for possible cures.

It is not to be expected that any marked step can be made at once in the treatment of so widespread and complicated a series of pathological lesions as those included under the generic name insanity; but gradually, very gradually, by encouraging those in authority in the various asylums to express in a practical form the views which they have come to entertain from their every-day observations of the tastes, requirements, habits and limitations of those under their care, we may frame a system by the judicious application of which some more tangible results may be obtained than it is our lot at present to command. And it is certainly only by encouraging personal initiative in, and by giving a freer hand to the heads of, our institutions for the insane that any progress can be made. Much, however, can be done in preparing the way at all times by those who take more than a perfunctory view of their responsibilities.

It would be outside the scope of these suggestions to enter into the details of so extensive a subject, and I must content myself with touching on one or two of the more important aspects of the question, which will illustrate my meaning and show how carefully the foundations of any new work in this direction must be laid. First, it is absolutely necessary that the general management of an asylum for the insane should be given to men of strong personality, men capable of influencing those who are working under them and of gradually imbuing the entire staff with the spirit of the ideas which they wish to put into practice. In giving a man the supreme control of such institutions, which are veritable communities, with a social as well as a medical interest, it should not be deemed sufficient that he has passed a certain number of years doing the routine work of an asylum. A man who is to be placed at the head of some hundreds of people should have other and more sterling credentials, and his fitness for the post depends on the personal asset of ideas he brings with him—the newer and broader views which will help towards the solution of the many problems he will have to face. Because a man is an excellent second is no criterion that he will be equally excellent in command.

Then there is the staff. Here we too often meet with people absolutely unsuited for their delicate mission, or in whom habit has killed all interest. These should be gradually but unrelentingly weeded out. Too much care cannot be taken in the selection of those who will be continually with patients mentally afflicted. Many people who have no absolute predisposition to any of the forms of insanity, but who are nevertheless of a retiring, brooding disposition—what is sometimes called "eccentric," and generally means morbid—are often apt to try and devote themselves to the care or nursing of the insane. These should be carefully dissuaded from such a step, for their influence on those they would benefit can only be unsatisfactory. It is those who are robust of mind, rather than those who are robust of body, who will make the best attendants for such cases. Cheerfulness, a satisfactory reason for entering on such a career, and a certain fine pity for the afflicted, with a common-sense view of life, will be the best attributes in those who are called upon to form the staff of an asylum. Once a suitable staff secured, they should, one and all, be made to understand that they are co-operators in a great humanitarian work, not simply keepers.

Then comes the all-important question of the inmates. It is impossible at the present time to formulate any particular theory, but I should like to emphasise certain faint indications as to a possibly more satisfactory dealing with the insane, when confined in an asylum, than has been the case in the past. Much has been done already in providing a certain amount of recreation for the inmates, and with excellent results so far as they go, but recreation pure and simple occupies the mind without, however, setting the mind in motion, so to speak. Occupation has also been provided for suitable cases, both in our asylums and abroad, but it is generally occupation of a mentally passive kind. On the contrary, should not our aim be, whenever we can, to make the brain of the patient work, to make him think, understand, remember? Elementary classes could be held in such subjects as history, geography, natural history, the teacher's descriptions being further emphasised by simple diagrams such as those excellent pictures issued by one of the societies for the promotion of Christian knowledge. The more intelligent could be given tasks to learn, and those who were successful encouraged by small prizes, to be given at the end of the course. In fact, it should be sought to re-open their minds in the same way and by the same methods as one opens the mind of a child. Of course, it would all have to be done in a very careful and tentative manner. It is already being tried here and there, but too much on the old lines, simply to afford distraction, not with an ultimate curative intention. The work must not be manual. Those who could not be persuaded to attend these classes could be taken into the garden and taught the more usual knowledge of flowers, which all those mentally afflicted love; then another day asked to repeat what they had been taught. Again, simple puzzles, such, for instance, as those now appearing in some of the papers and magazines, where some simple image suggests the name of a town, could be distributed at all times through the wards and prizes given to the successful competitors. The difficulty would be to induce the patients to interest themselves in these competitions, but it would suffice that, one or two started, the others, on seeing the prizes, would soon join in. These are only a few among many possibilities.

What strikes one in going through any asylum is the general listlessness of the inmates, the passivity in which they are left and which is most detrimental to them. Reading aloud to them short, simple, interesting stories in the wards or at meal time should be much more in vogue than it is, and this could be done by outside helpers, for many who have spare time would be only too glad to devote some of it to such good purpose. It should be sought as far as possible to make the inmates realise that they are members of a community and take interest in pursuits in common. For this, and as a clearer understanding of their abilities was arrived at, it would be probably advisable to divide them accordingly, and not merely as is done at present into acute and chronic cases. Theatricals, dances, music, are all very well, but there is an element of excitement about them, while such occupations as I have suggested would be of everyday occurrence, and would partake of something of the regularity of school life.

It is by working after such or similar methods that the general management of our asylums will find its more utilitarian, mission and a step forward be made in the more rational treatment of the insane.

France.

FRENCH MEDICAL HEROISM.

By F. R. Wolfe, M.D., F.R.C.S.Edin.

Amidst the constant and sudden changes which are taking place in this country, and the disappearance of some of our most cherished institutions, it is satisfactory to find that the race of medical enthusiasts is still flourishing. I had the pleasure the other day of making the acquaintance of Dr. Paul Garnault, a gentleman who has inoculated himself with matter from a tuberculous cow, in the expectation of producing in himself general tuberculosis, and thereby to prove the identity of bovine and human tuberculosis. In reading the notices which have been published in the daily papers regarding Dr. Garnault's procedure, one is apt to dismiss the case merely as an attempt to court notoriety; but on personal contact with that gentleman, and a critical examination of his large work on the subject, consisting of 1,050 pages, which was published the other day (a), we are forced to give him credit for being an able and serious scientific worker, and we are ready to agree with Professor Blanchard, who speaks of "Dr. Garnault's heroic self-abnegation" in terms of profound admiration. I remember one Paris physician who applied a diphtheritic membrane to his tonsils, and another who swallowed a pill made of the excreta from a cholera patient. The late celebrated Professor Pettenhoffer, of Munich, also drank water containing cholera bacilli. These experiments were made to prove the innocuity of the substances, but Dr. Garnault's object is to prove the fatal effect of the experiment.

The psychological process by which he has been led to this determined attempt at self-slaughter is quite natural under the circumstances. Garnault is a Doctor of Medicine as well as a Doctor of Natural Sciences, ex-Chef of Zoology and Comparative Anatomy of the Faculty of Science of Bordeaux, and Member of the Anthropological Society of Paris, and has published several works on these subjects. He has, moreover, taken part in the movement to enforce the law against the sale of flesh and milk from suspected animals, it being his belief that 100,000 children besides adults die every year through the infection of bovine tuberculosis. He *was* a staunch adherent and admirer of Professor Koch, and attended the memorable London meeting in July last year. The meeting was intended to be a great demonstration—a crusade against tuberculous flesh and milk. Professor Koch, who was expected to support the crusade, by some new development of his theories, informed the meeting that from recent experiments which he had made upon animals, he found that tubercle in animals (perlsucht) was quite distinct from human tubercle and that they are not transferable to one another, and that the flesh and milk from tuberculous animals were quite safe for consumption.

(a) "Le Professeur Koch et le Péril de la Tuberculose Bovine."

The consternation of the meeting at this pronouncement can hardly be described. It was as if the late Mr. Spurgeon had used the occasion of a revival meeting in his tabernacle to announce his going to join the Church of Rome; or if Pope Leo himself had proclaimed his conversion to Scotch Presbyterianism. The day following the London meeting, the late Professor Virchow, addressing the Clinical Society of Berlin, said that for the last ten years he had been teaching that, bovine tuberculosis (perlsucht) was quite different from human tuberculosis, and he was at a loss to see how they could be considered identical. The German Government appointed a Commission to examine the question, Virchow being its leading member. "At that meeting," he said, "I shall insist to distinguish between *pathological* and *bacteriological* tubercle. The bacteriologist, when he dissects a wart and puts it under the microscope and discovers a bacillus, thinks that there must be millions more, and calls it tuberculous, but the bacillus does not constitute tubercle. I am not afraid to eat flesh or drink milk which contain bacilli," &c.

After the publication of the opinions of Koch and Virchow, the subject was made the sport of the French Philistines. Mons. Theodore Denis (Member for Lourdes) made an eloquent and humorous interpellation at the meeting of the Chamber of Deputies, March 20th, 1902, on the tuberculous flesh and milk question. Referring to the opinions of Koch and Virchow, he said: "Everybody rejoices at the declarations except the veterinarians who make an outcry against the German savants." "What right have these Berliners to interfere with our bacilli? Let them mind their own business. Let us be armed with our tubes to defend the sacred microbes who nourish our families!" Referring to the number of poor children who die in Paris annually from the infection of tuberculous milk, Mons. Denis said, "I cannot get genuine milk in Paris. I advise some members to visit the populous districts and ask for a drink of milk. You will get water and chalk or plaster. You will get colic, but no tuberculosis."

To combat these pernicious errors Dr. Garnault has thrown himself into the breach. When the soldier seeks the bubble of reputation at the cannon's mouth, why should the man of science, in a great emergency, hesitate to reap immortality by offering himself as a holocaust to science and humanity? Besides, it is a good principle, from which, if bacteriologists were to adopt it, we might get more trustworthy results. Dr. Garnault went to Berlin and offered himself to Koch for experimentation; but, as Koch and other medical authorities refused responsibility, he performed the operation upon himself in the presence of two medical men. In the first operation, having applied a fly blister to the forearm, he went to an abattoir, where the blistered epidermis was removed and the raw dermis scraped with a bistoury. Tuberculous substance from the ganglion of a tuberculous cow was applied to the wound and secured by a bandage. There was no fever nor ganglionic disturbance at the armpit.

The first experiment having proved negative, he operated a second time by making an incision into the dermis, lifted it, and put into the wound tuberculous matter from the liver of a tuberculous cow. No reaction and no ganglionic disturbance followed. The wound suppurated. A section of the skin being then examined microscopically giant cells and bacilli were discovered. Another part of the section and some pus was given to Pasteur's Institute, and used to inoculate guinea-pigs, &c. The result of this inoculation has not yet been ascertained. Dr. Borell, of the Institute, who acts for Dr. Roux, just now tells me that all the steps of the process were done antiseptically and *secundum artem*, and he expects shortly to report.

Dr. Garnault, age 42, of robust health, has no family. Should the operation prove successful, he will not undergo any treatment for cure, but bequeath his body to the Academy for post-mortem, who will very likely raise a statue to him beside that of Bichat.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, September 6th, 1902.

At the Society for Medicine Dr. Glaser discussed the Significance of the Typhoid Bacillus in Diseases of the Respiratory Tract after Typhoid Fever. He reported two cases. A physician, æt. 31, had worked with typhoid cultures of a highly virulent type, and was attacked with the disease. After fourteen days he developed pain in the chest, shortness of breath and fever, pneumonia of both lower lobes, and rust-coloured expectoration. In the fourth and fifth week right-sided empyema appeared, with highly virulent bacilli in the discharge. The empyema disappeared partly after aspiration and partly by expectoration. As only typhoid bacilli were found in the expectoration it might be assumed that only typhoid bacilli were present in the lung patches, and that these had set up the changes in the lungs. The prognosis of an empyæma so set up was, he observed, more favourable than if set up by streptococci. Generally, in lung complications in connection with typhoid, pneumococci were the exciters. When typhoid bacilli were found in expectoration or in the tissues after death, it was not proved thereby that they were the exciting agents of the complication, for, as a rule, pneumococci were also found, and in such quantities that they must have been the agent in the production of the disease.

This accessory *role* of the typhoid bacillus was shown by the following case. A woman, æt. 45, became ill with symptoms of pneumonia in the right lower lobe, and at the same time she had all the symptoms of typhoid fever. In the rusty expectoration, along with pneumococci, were bacilli that resembled those of typhoid, but no pure cultivation could be obtained. By puncture at the site of dulness, lung juice was obtained. The autopsy showed that the case was one of typhoid in the seventh week. There was also a fibrinous pneumonia in the right lower lobe. Microscopical examination of the hepatised tissues showed quantities of pneumococci, but only a few bacilli resembling the typhoid bacillus. These could only have been of accessory importance, the exciters of the pneumonia being the pneumococci, and the typhoid bacilli had only reached the part in the blood by accident.

In another case the bacilli were present in the expectoration in large quantities. A man, æt. 29, was convalescent from a moderate attack of typhoid fever. In the fifth week dulness suddenly appeared in the right lower lobe of the lung. The rather free expectoration was in parts distinctly rusty. There was also pleural exudation on the right side. After a few weeks the patient recovered. Examination of the expectoration showed, along with pneumococci, numerous bacilli that resembled those of typhoid. Cultivation showed two distinct colonies—pneumococci and typhoid bacilli. The bacilli could be seen in the expectoration for fourteen days. In a patient of Dieudonné's they persisted for seven weeks. It was important to recognise the nature of the bacilli quickly in order to avoid infection from the expectoration. As regarded the differential diagnosis of lobar pneumonia in the course of typhoid fever, Curschman had observed that in typhoid pneumonia the sputum had a hæmorrhagic character and this observation had been confirmed by others. A. Fraenkel, on the otherhand, held this hæmorrhagic expectoration to be a sign of hæmorrhagic infection.

The *Deutsch Med. Z.*, No. 68, contains a reference to a contribution towards the

Treatment of Puerperal Fever by Crede's Silver Ointment.

This ointment, known commercially also as collargolum, has been much recommended in all cases in which the strepto- or the staphylo-coccus is the originator of the disease.

A woman, æt. 39, who had had four children and three miscarriages without trouble, developed infection soon after her confinement. From this developed inflammation and œdematous infiltration of the pelvic tissues, especially between the layers of the left broad ligament. This parametric exudation gradually extended up to the crest of the ilium, then backwards and downwards almost to the anus. In spite of the use of the silver ointment the swelling remained for months. At first the temperature was rather high with intermissions, and the inunction of 24 grm. of the ointment from the seventh to the eleventh day had no marked effect in reducing the temperature. The fever did not cease until the third day after the eighth inunction. The author thinks it possible that the silver ointment caused the cessation of the high temperature.

The same journal records a

Rare Complication of Puerperal Fever.

A woman, æt. 28, became feverish on the second day after delivery, the temperature at first being 39° to 40°, and for ten to twelve days it was 39° in the morning and 40° in the evening. But the patient was subjectively well and in good spirits; the abdomen was neither distended nor painful. After this time the fever subsided, but a swelling like phlegmasia alba dolens developed in the left thigh, which was doughy but not painful. A week later a similar swelling appeared in the right forearm. A large quantity of pus was removed by incision. A sound passed deeply and encountered the rough bone of the femur denuded of periosteum. After some time the incision had to be enlarged, after which the patient recovered. Possibly, it is suggested, the case was one of self-infection from passage of bacterium coli from the intestines, or the germs of erysipelas from the inner surface of the uterus. All antiseptic precautions had been used, and the uterus had even been washed out with a rather strong solution of sublimate—1 in 2,000.

Austria.

[From our own Correspondent.]

Vienna, September 6th, 1902.

Delayed Rickets.

At the "Gesellschaft für Innere Medizin" Gottlieb showed a case of severe "florider rhachitis" arising from fæcal retention.

The patient was a boy, æt. 7½, of robust parents, who was born healthy and strong, and had four healthy sisters. Beyond an attack of mumps there was no other history of febrile attacks. He seems, however, to have suffered from dyspepsia, with alternating diarrhœa and constipation. About the end of his first yearof life rickets appears to have set in, which, judging from the history, did not yield to treatment. Of late the child had been growing weaker, the bowels more confined, and his general condition so alarming that the parents brought him into hospital.

On admission he appeared very pale, emaciated, and extraordinarily backward; he could neither walk nor stand, and could only creep on the floor with great difficulty. He was 80½ centimetres in length, or 31½ inches, and 11 kilogrammes, or 24·2 lbs. The cranium was slightly rachitic, but not so much as usual. The contour of the thorax was strikingly malformed and irregular; the upper and middle portion being greatly constricted, while the sternum stood forward like a wedge, and the convexity of the ribs was converted into a concavity. Both hypochondria were immensely enlarged, this giving a small appearance to the chest. Both clavicles, as well as the ribs, had large deposits of callus, as if fractured in many places. There was also kypho-scoliosis, which further added to the deformity of the chest.

The respiratory sounds were puerile but no râles; the heart greatly displaced; but no morbid change could be discovered in the sounds, although the pulmonary valve was slightly accentuated in the second sound and the respirations accelerated to forty in the minute. The extremities were greatly emaciated and the inactive muscles soft and atrophied. When resting in bed the legs formed a ring, with the abdomen, which was enormously enlarged, filling the circle. On palpation firm swellings about the size of hen's or pigeon's egg were to be found in the bowel. These were of an ovoid shape, moveable, and without pain on pressure, but into which the finger could be slowly pressed, leaving an indentation, a symptom which Gersuny has termed "Klebs-symptom," as pathogenic of fæcal matter retained in the bowel. To relieve this accumulation "high irrigation" was performed with 1½ litres of water, and an enormous mass of dark, offensive, and scybalous fæces dejected, with considerable pain to the child. After three repetitions the tumours all disappeared.

In the diagnosis it must be admitted that there was a "causal nexus" between the rachitis and these fæca tumour formations; the conjugate diameter in this boy was only 2½ centimetres, which is not an inch wide, being only 0·984 in. We may therefore conclude that two forces were active in the production—(1) the mechanical obstruction in the discharge of well-formed fæces, and (2) by the narrowing of the pelvis, a dislocation of the sigmoid flexure, which in children is relatively large and thus easily producing looping of the bowel, and further increasing the difficulty of the passage of the fæces, as in "Hirschsprung" disease.

The treatment must be rational: First remove all fæcal accumulations by careful washing out, but never by purgatives, applying massage to the inactive abdominal muscles; give phosphorised cod liver oil, good diet, and orthopædic interference if really found necessary to correct any deformity and relieve the free passage of ingesta.

Offer next gave a record of the examination of the patient's urine, in which there was a large quantity of aceton, and about 0·1 per cent. of sugar. He said this was a common occurrence when tumours were present in the abdomen, but not usually observed in constipation, although it is reasonable to suppose that any form of compression on the large lymphatic vessels will produce the same morbid change of glycosuria. This concords with Biedl's experiments on animals, as he found that tying the ductus thoracicus or conducting the lymph out of the body produced sugar in the urine. He related the case of a man under his care, with all symptoms of an abdominal growth, which was diagnosed as the pancreas at first, but subsequently not so, as there was no fat in the stools, while iodoform glutinoids and salol were physiologically split up—yet there was glycosuria. The final diagnosis was compression of the ductus thoracicus by some morbid mass and this was confirmed by the abduction.

Schwarz remarked that the appearance of alimentary glycosuria through the closing of the ductus thoracicus was not free from objection, although experiments on animals had been successful in demonstrating this fact.

He had in his mind when he said this a case which he carefully followed where no such morbid product ever appeared, though genuine chylous ascites was present, in consequence of complete closure of the thoracic duct. The case commenced with cirrhosis of the liver, atrophy, closure of the duct, finally terminating in œsophageal carcinoma.

Secondary Carcinoma of the Pleura.

Sorgo demonstrated the origin and descent of epithelial cells in secondary carcinoma, which has often been debated with very little success. With the aid of the microscope he endeavoured to show four different types of cells: (1) The round large cell, varying in size from five, ten, or more times that of a white-blood corpuscle, having a clear nucleus with fat in the protoplasm. (2) The epithelial polymorphic cell, whether oval, crescentic, pear-shaped, or caudate. These cells have usually out-growths, or strangulated portions, and nuclei in subdivision. (3) Vacuolar cells. (4) Cell-union, which comprises a large type of forms ill to define.

On referring to the literature on the subject and different methods of diagnosis, he found the various elements in the product were regarded as important, such as—(1) Hæmorrhage or chylous fluid, which, he thought, was of less value than the glyco and fatty degeneration of the cell. (2) Epitheloid element, with or without vacuolisation, which is highly suspicious of a neoplasm. (3) The polymorphic, polynuclear and giant vacuolar cells are also regarded as indicative of neoplasms. (4) Primary epithelial cancer has, as a rule, a small amount of exudation, while secondary carcinoma has a large quantity. A rich cellular serous fluid also bespeaks secondary carcinoma, but purulent hæmorrhage with this condition is not confirmatory evidence. (5) The form and arrangement of the cells not infrequently give an exact histological diagnosis of the case. Among other recommended confirmatory tests of secondary cancer thrown out for the student are the sediment, hardened, cut, and then examined, colouring of the mucus, or the formation of the epithelial fibres.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Operation for Colotomy.—Mr. Barrow's Method.—Mr. Boyce Barrow operated on a man, æt. about 55, who was suffering from extensive malignant disease of the rectum. An incision was made through the abdominal wall about midway between the umbilicus and the anterior superior spine (being a little nearer the latter). The peritoneum was opened, and the colon then brought out of the wound; the situation having been selected in the gut suitable for the artificial opening, the next step was to make an opening into the meso-colon sufficiently large to admit the fingers, this opening being under the selected spot in the colon. Sutures were next passed through the abdominal wall incision a little below its centre, passing underneath the colon through the opening before made in the meso-colon, joining the incision for a short distance nearly at its centre and thus dividing the opening in the abdominal parietes into an upper and lower part, so that the colon passing out through the upper opening rested on a bridge formed by the sutured centre of the abdominal wound and then re-entered the abdomen through the lower opening. A piece of protective gauze was applied to the surface of the bowel and the wound dressed in the ordinary way. Mr. Barrow said the chief features in which this process possessed advantages are: the ready way in which the operation is performed, the absolute security of the bowel from any liability to recede, besides which the opening provided for the escape of fæces is such that it is impossible for any fæcal matter to pass into the lower bowel after the opening is made into the colon. There are, he remarked, cases in which the bowel is so bound down on account of the disease or by a short meso-colon that the colon cannot be brought out of the wound to be fixed satisfactorily, but in this operation the bowel is freed sufficiently to allow the surgeon to bring it easily out of the abdominal opening. The easy manner with which the fæces escape enable the gut to be so perfectly purified that an operation on the lower bowel can be subsequently performed with all the advantages of an aseptic operation, and moreover in cases in which it is impossible to remove the disease there is no liability for the diseased surfaces to be irritated by the passage of fæcal matter. Mr. Barrow has found that after this operation the wearing of a belt is so satisfactory that the patients experience but very little discomfort from the artificial opening.

MIDDLESEX HOSPITAL.

Operation for Fractured Patella.—Mr. Kellock operated on a woman, æt. 35, who had been admitted for a transverse fracture of the right patella, which had taken place a few days previously. The patient was a stout, healthy-looking woman. An X-ray photograph showed that the fracture had taken place about the centre of the bone, and that there was considerable separation of the fragments. The joint was still considerably swollen, and the surrounding skin showed evidence of extravasation of blood. The patient was also the subject of extensive varicose veins in the same limb. The woman having been anæsthetised, a curved incision was made from about an inch above the upper border of the upper fragment curving inwards along the inner border of the bone and reaching to the centre of the ligamentum patellæ. The flap thus marked out was turned up towards the outer side; whilst this was being done a quantity of dark-coloured blood escaped as the joint was opened between the separated fragments. It was then found that there was a considerable quantity of blood clot in the joint and between the ends of the bones; this having been removed by swabbing, the upper and lower fragments of the bone were brought together by two wire sutures passed through the greater part of the thickness of the bone but not involving the articular surface; the wires having been drawn tight, the ends twisted and hammered into the front of the bone, and the fragments having been found to have been brought into good apposition, the V-shaped lacerations in the capsule on either side of the joint were closed with fine silk sutures, and the skin-flap then replaced and kept in position by a continuous horse-hair suture. Double cyanide gauze and mercurial wool were used as a dressing, and the limb lightly fixed to a back splint. Mr. Kellock said that the operation he had just performed was the one he considered the best in attempting to restore a fractured patella; he pointed out that, provided every care was taken, the risk of any septic trouble was little, if any, greater than in the methods of subcutaneous suture. He remarked that one generally had the opportunity in these cases of keeping the patient under observation for a few days previous to the operation, and during that time the skin could be thoroughly sterilised. The advantages of the operation were: the certainty with which all clot and tissue could be removed from between the fragments, the exactitude with which the fragments could be brought into apposition, the fact that the wire sutures could be passed in such a manner as not to enter the cavity of the joint, and the possibility of suturing the rents in the sides of the capsule. He considered that an important point in doing such an operation was to avoid the introduction into the joint of any chemical antiseptic, and he drew attention to the fact that for swabs, instruments, &c., nothing but plain sterilised water had been used. He pointed out also that the use of the back splint was merely temporary until union should have taken place in the skin wound; it would then be removed, and the patient allowed to gradually regain movement of the joint of her own accord.

The Treatment of the Insane.

The International Congress for the Improvement of the Condition of the Insane was opened at Antwerp last week, under the presidency of M. Van den Heuvel, Belgian Minister of Justice. The delegates present include representatives of most of the leading countries of Europe, as well as of China, and specialists from various parts of the world. The general feeling so far appears to be in favour of cottage settlements in preference to asylums as a means of treating insanity.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 10, 1902.

WORK OF THE LOCAL GOVERNMENT BOARD.

The issue of this bulky volume of 676 pages (1900-01) is an event of importance in the annals of preventive medicine. The medical officer, Mr. W. H. Power, presents the usual record of administrative work conducted by the Department during the twelve months, especially with regard to vaccination and plague. He also recounts the result of a great number of valuable auxiliary scientific investigations. It says much for the energy of this Department that time can be found for laborious researches of the kind, in spite of the enormous amount of administrative work with which it is overburdened. The scientific side of preventive medicine, as cultivated by the Board, presents the nearest approach to a national scientific endowment with which we are at present provided. It may possibly form at some future time the nucleus of a public scientific research laboratory worthy of the British Empire. Meanwhile the administrative field of public health work is wide enough to demand the energies of a strong and powerful organisation. These criticisms are made in no hostile spirit, but with a sincere wish to further the efficiency of a Department that has done more towards the development of practical hygiene than any body the world has yet known. The variety and abundance of the enquiries conducted by the Medical Department may be realised by a study of the report under notice. The official year 1900-01 will be long memorable on account of the arsenical beer-poisoning outbreak in Manchester and the neighbourhood. The discovery of the epidemic was due to the acumen of Dr. E. S. Reynolds, and the Board at once recognised the importance of the matter. One of the great functions of the Board, as everyone knows, is to conduct detailed inquiries into the sanitary condition of districts where outbreaks of disease have occurred. A typical instance of the need of such supervision is afforded in the case of Boston, in Lincolnshire, where both enteric fever and diarrhœa have prevailed to an undue extent for a prolonged period of time. The sanitary state of the town is scandalously defective. The sewage is discharged into the river Witham at a point which entails its passing in its course seawards through a large part of the town. A farmhouse affords the only infectious accommodation for a town with a population of 30,000 or 40,000 inhabitants. There is no disinfecting apparatus, the water supply is defective, and the bye-laws are out of date. The criticism of the Medical Officer seems hardly adequate when he remarks that the history of Boston set forth by his Majesty's inspector shows the disposition of certain local authorities to remain content in sanitary matters with the methods and procedures of their predecessors. In a word, the Boston Town Council is apparently concerned rather in furnishing plausible excuses for its shortcomings than in setting to work to improve the conditions of its district. The auxiliary scientific investigations cover so much ground that it is out of the question to attempt anything more than a general notice. The experiments of Drs. Klein and Houston, however, may be noticed. They deal with the behaviour of cereal products in connection with specific bacterial contaminations. This subject deserves careful investigation because of its importance with regard to bread, the non-sterilisation of which was demonstrated some years ago by two medical men. The results of the present research show that the microbes have no tendency to multiply in the mixture of cereal and bacterial culture. On the contrary, the action of the cereal was fatal in a few days to the vitality of the microbe. These experiments are reassuring so far as they go, but they appear open to some amount of fallacy which would forbid any sound general conclusion at the present stage. Dr. Klein has proved that both cockles and mussels readily take up from sea water the microbes of enteric fever and of cholera, and that they can retain in their interior these germs of disease for some days after they have been withheld from further contamination. The practical bearing of these facts is self-evident. Good work has also been done in the direction of freeing vaccine lymph from extraneous organisms. The whole Report, indeed, forms a valuable mine of suggestive information to the scientific student of public health. It is illustrated profusely with maps and photographs, whereby the text is considerably enhanced in value.

BERI-BERI.

The exact nature of this disease is still a matter of active speculation, and, though we possess certain facts as to its immediate causation and general symptomatology, these are in no way conclusive and are often apparently contradictory. Though attacks of beri-beri are often brought on by inadequate food, and especially by a continued dry farinaceous diet, and are thus occasionally met with during the long voyages of sailing ships, this only accounts for a certain percentage of the total number of cases. It must be remembered that the disease is endemic in Borneo, Java, and Sumatra, and indeed it would seem as though it had originated there, its spread to other parts of the world, in many cases, being directly traceable from this focus. For instance, beri-beri was unknown in the Guianas until the Dutch imported coolies from their eastern possessions to work the sugar estates. In the general hospital at Paramaribo, in Dutch Guiana, there are now always between twenty and thirty cases of this disease under treatment. From Dutch Guiana it has spread to the north of Brazil, and is rampant in Para, while the more southern ports are comparatively free from it. About three years ago, on a training-ship of the Brazilian Navy stationed at Para, over two hundred cases occurred, and it was only when the vessel shifted to Pernambuco that the epidemic began to abate. This was distinctly not the case of a crew deprived for a long period of fresh meat and fresh vegetables, for all that was required could be obtained from the shore. There is evidently here a causal element which is of great importance, and which has not received adequate attention. That beri-beri has some of the features of multiple neuritis is beyond doubt, but so far the bulk of the evidence is not favourable to the theory that they are one and the same disease. While beri-beri is endemic in certain places, may become epidemic under certain conditions, and is often determined by unsuitable food and lowering physical influences, these are not conditions associated with multiple neuritis. Again, there is rarely loss of sensation in the former disease, rarely visible complications in the latter. In the acute form of multiple neuritis the great danger is paralysis of the respiratory muscles, while this is only a very late contingency in the most chronic form of beri-beri. In acute beri-beri, general dropsy, with effusions into the serous cavities, hæmorrhages from the alimentary canal, a puffy, earthy, anguished face, and a fluttering pulse are symptoms which rapidly appear, and recovery is rare in severe cases. Patients affected with this disease have a tottering, jerky, dragging gait which is quite typical. Even in the less acute forms recovery is uncertain, and the patient may linger on for years helplessly paralysed. There is at present in one of the London hospitals a man who has been suffering for six years from beri-beri, and who is bedridden. He was one of three cases which occurred among some Anamites who came over to give performances in London, were herded together in a tenement in Westminster, and fed on rice, and that sparingly; one man died of the disease, the other was removed to the hospital in question, and the third recovered. Professor Uchermann, who has been for some time collecting evidence about this disease from Colonial and ship doctors and master mariners, and who has recently given the results of his investigations to the Norwegian Scientific and

Literary Society, concludes that beri-beri is the Oriental name of multiple neuritis, and is due to a toxin intoxication by tainted vegetables. Neither of these conclusions can, however, be considered definitive, but it is certain that general debility brought on by overwork and unhygienic surroundings combined with inadequate and unsound food of any description, though more especially when it is largely composed of preserves, have a determining influence in the causation of the disease. One point in Professor Uchermann's report is especially worthy of notice in this connection. He finds that it is on Norwegian ships that the disease is more often found than on those of any other nation. There is a reason for this. The regulations affecting sailing ships are in Norway and Sweden much less stringent than those, for instance, of the Board of Trade in England. The result of this is that many shipowners in England, and probably in other countries, in their greed of gain, and to escape the restrictions and expenses imposed on them, engage a certain number of Norwegians among their crews, register their ships in Norway, and fly the Norwegian flag. These ships are undermanned, the regulations for the general health and protection of the crew enforced by the Board of Trade are evaded. These ships are familiar to all who have travelled in distant parts, and constitute one of the worst features of modern mercantile enterprise. Though the vessels are not strictly speaking Norwegian, Norway and Sweden deserve the bad name which has attached itself to their shipping, for allowing their flags to cover a state of things which other countries will not tolerate. The fact that beri-beri is more prevalent on these ships than on any other, however, emphasises one point, which is that indifferent and insufficient food, with debilitating and unsanitary surroundings, are factors not unimportant in connection with this disease.

THE ABUSE OF FOOD PRESERVATIVES.

The licence which is granted to manufacturers of preserved foods in regard to the nature and quantity of the chemical preservatives which are used is not, we fear, always used to the good of the public. So long as these preservatives are of a comparatively harmless nature, the advantages accruing from their use perhaps counterbalances their disadvantages; but the case is very different when lethal drugs, such as carbolic acid and hydrofluoric acid, are used. In the curing of bacon and hams both carbolic acid and boric acid have latterly been much used. The former gives, when discreetly used, the vraisemblance of the peat smell of Irish ham. And it is urged that in the process of boiling the meat almost all the free acid is dissolved out. Boric acid, when used in the preservation of "mild-cured" hams and bacon, has a special danger. The process of boiling removes the acid and practically all the preservative agent; for the first day such meat has the mild flavour now so much relished, but the meat does not keep more than two or three days after boiling; it develops artificial ammonias, ptomaines, and other toxins. But one of the worst of the preservatives is quite a new addition to the list, fluorine. For a considerable time past the French peasant added a fluoride to the market butter, and now the custom is being adopted in this country. It will not be long before its effects are noticeable, and we write in the hope that the authorities, may take cognisance of this, the worst form of preservative that can be used. The caustic effects of nascent hydrofluoric acid on the mucous membrane of the stomach are most destructive; in children they would be rapidly fatal by arresting digestion. We are aware that hydrofluoric acid, and the fluorides of ammonium, iron, and quinine were fairly tested during the eighties in diphtheria, bronchocele, phthisis, and splenic enlargement, and although favourable accounts of them were received they are not much used to-day. There is, however, a wide difference between the medicinal use of a drug by a patient under medical observation and the daily use of the same drug in unknown quantities with our daily food. It is fortunate that hydrofluoric acid is easily recognised by its corrosive action on glass. We do not ask for the absolute prohibition of such chemicals as are not lethal and only very mildly toxic, but we do ask for a law compelling the vendor to state if his ham is cured with boric acid or phenol, or his jam kept sweet with salicylic acid, and we would like our milkman to notify the amount per quart of formic aldehyde he was supplying. All we ask is that the public be told in plain English what they are buying.

Notes on Current Topics.

Prostatectomy.

For centuries the treatment of enlarged prostate has been the opprobrium of surgery. The many methods and the many minor operations devised for its amelioration simply serve to emphasise the dread of interference with the gland that dominated the surgical mind. There was no lack of information on the anatomy of the region in the normal state, and Holmes' great work has familiarised every tyro with its abnormal state and naked eye pathology. Withal when some bold spirit suggested operation, and hinted at its removal, he heard of its vascular relations, and was reminded that the same relations once formed the subject of a great trial and killed the reputation of a great surgeon. Yet the do nothing treatment was productive neither of relief to the patient nor of credit to medicine. Brodie, in a fit of desperation, introduced his "bloody and brutal" operation; and though he succeeded in effecting the canalisation of the central lobe, others not alone failed, but by their violence tore the central lobe away, and in some instances the patient bled to death. For almost a century the bladder was considered, as far as prostatic troubles, outside the province of surgery. Numerous placebos were painted over the perinæum to promote absorption of the gland: belladonna, iodine, iodide of potassium. But the patients found no more relief from the physicians than they did from the surgeons. Once again the surgeons came forward with their suggestions, and castration, section of the cord, and a number of minor operations were tentatively tried; the capsules and the vascular relations were still the bogies that prevented the relief of the victim. This dread was all the more unaccountable because the elder Ellis had shown many years ago in Dublin that the prostatic enlargements were due to the growth of the glandular tissue, the removal of which entailed no risk of bleeding. This fact has been proven repeatedly and by none more successfully than by Goodfellow, of California, who, by following the median perineal incision of Manzoni, better known as Allarton's median lithotomy incision, has since 1896 successfully scooped out with his finger the hypertrophied glandular tissue in twenty-four cases without one untoward symptom. In not a single case was he called on to tie a vessel. Mr. P. J. Freyer's operation for the total extirpation of the prostate through a supra-pubic opening in the bladder has in his hands yielded excellent results, so that all round the immediate prospect of surgical relief in prostatic enlargement is a very hopeful one.

The Fate of the Aged Poor.

In spite of much talk and various irregular efforts, the condition of the aged poor in this country is distressing. It is time that we realised that the sick poor and the senile subject should be considered as having fallen victims to pathological processes, and consequently should be freed from the ban of pauperism. The conglomerate aspect of the average workhouse is a blot on our social system; but the road to release and adequate redress is hard to find. Miss Edith Sellers, in the current number of the *Nineteenth Century and After*, records the result of an investigation which has sought to ascertain if an old-age pension of five shillings a week to those above sixty-five years would enable them to keep outside the workhouse. In the special workhouse inspected 288 men and 437 women were found to be over sixty-five. Of these 427 were infirm, worn out, broken in health, or the subject of definite disease. Of the remaining 298 hardly one in four but was burdened with some infirmity. Of these 100 were men and 198 women, and of the women 7 were wives, 170 widows, and 21 spinsters. Of the old women 62 had no relatives, and 32 more, for practical purposes, were in the same position. Of the 198 luckless old women 96, at the least, stood alone in the world. Of the 102 who had relatives, 50 frankly confessed that their people could not or would not take them in, five shillings or no five shillings. After careful sifting, it appeared that out of all the 437 women there were only 15 who even thought they would be able to leave the workhouse were the old-age pension law to come into force. Of the 100 men only 24 declared themselves as quite alone in the world. No fewer than 90 declared that even if they had pensions they had nowhere outside the workhouse to go to. It seems that so far as the 725 senile cases investigated are concerned, the effect of an old-age pension would be practically *nil*. In the London workhouses alone at the present time there are more than 20,000 persons above sixty-five years. For the majority of these more or less medical and nursing supervision is desirable. Unfortunately, even for our sick poor adequate accommodation is often wanting, and for "worn-out" humanity our arrangements stand in need of much improvement. It is to be hoped that means will be found to solve the problem. Medical men have opportunities of studying the question in some of its practical aspects, and it may be trusted that they will take their proper part in seeking a solution.

Municipal Control of the Ice Cream Trade.

After November 1st next the Medical Officer of Health of the City of London will assume control over the manufacture of ices, ice creams, and similar commodities intended for sale. This is a reform for which we have long contended, and the example of the City of London will no doubt be promptly followed by other municipalities throughout the kingdom. In future it will be compulsory on manufacturers to notify the outbreak of any infectious disease among their *employés*, and every vendor, not himself the manufacturer, will have to place in a conspicuous place on his barrow the name and address of the persons from whom he obtains his supply, or his own should he himself be the manufacturer. The frequency of outbreaks of quasi-epidemics of gastro-enteritis distinctly traceable to the ingestion of ice creams sold in public thoroughfares, and the fact that these are for the most part prepared under conditions which violate the most elementary rules of hygiene, fully justify this departure; indeed, it is a matter for surprise that this lapsus should not long since have been remedied.

Intemperance and Infantile Mortality.

The unavoidable infantile death-rate is at present usually estimated as 100 per 1000. But the actual waste of child life in many districts is enormous. Dr. E. W. Hope, the Medical Officer of Health for Liverpool, in his recent annual report, refers to this matter. In the course of a systematic investigation of 1,082 families in which death of an infant had occurred it was found that the total number of children born in these families had been 4,574, but that 2,229 had died, practically all in infancy, thus representing a death-rate of 487 per 1,000, a waste nearly five times as great as the standard above mentioned. In twelve families in which the large total of 117 infants had been born no less than 98 perished. The circumstances of the families in which upwards of 1,000 consecutive deaths had occurred were investigated. In 21 per cent. the families were extremely and exceptionally dirty; in 18 per cent. the mothers went out to work, leaving the infant in the custody of others, frequently merely in the charge of another child; about 11 per cent. were living in homes unfit for habitation. But drunkenness seems answerable for an enormous amount of the neglect and suffering which bears so heavily on child life. In upwards of 25 per cent., and these are the cases where the mortality appears to be highest, the parents were markedly intemperate. The prospects of the life of the infant are indeed poor if the drunkenness of the mother results in starvation and neglect during her bouts of drunkenness. In many cases, also, the intoxicated state of the mother leads to accidents and serious or fatal injury to the child. But, sadder still, violence and brutality play a large part. The extreme suffering inflicted upon child life by intemperance, and the loss of life immediately resulting from it, present one of the saddest features of city squalor and seem beyond the powers of sanitation to effect a lasting reform.

Life Protection Service for Seaside Police.

THE lamentable loss of life which accompanies the annual exodus to the sea-coast is one of the dark blots on our holiday season. Much of this sacrifice is strictly avoidable, and usually arises from ignorance, recklessness, or neglect. We are strongly of opinion that sufficient means are not taken to secure adequate protection for visitors at many of our seaside resorts. It is monstrous that ambitious advertising town councils should expend vast sums of money in showing that their particular borough is the most sanitary and health-giving in the country, and yet neglect to provide proper protection to the children, invalids, and holiday makers who are attracted thither. At all seaside resorts the police should be selected for their skill and suitability in dealing with the particular class of case likely to come under their notice. In many places the law seems to exercise no particular oversight over the sand and shore, at all events a policeman is usually conspicuous by his absence. Surely the time has come when progressive watch committees could arrange to provide water police, men who, during the season, should patrol the coast line in boats, watch swimmers, guard children, be able to render adequate first-aid in needed cases, and so do something to prevent the deplorable loss of life which makes a visit to the seaside a dread to many and a disaster to some.

The Making of Mankind.

WE could wish that Mr. H. G. Wells were a member of our own profession. As a scientist Mr. Wells has gained distinction, as a novelist he has won fame and popularity, as a prophet he has sought to unmask the future, and now as a teacher and profound thinker he is attempting to mould men's minds into the acceptance of altruistic views which doubtless in many a medical man's inner consciousness has waited a suitable expression. Mr. Wells, in the current number of the *Fortnightly Review*, gives us the first instalment of his brilliant essay on "Mankind in the Making." He seeks to show that any collective human enterprise, institution, movement, party, or state is to be judged as a whole and completely, as it conduces more or less to wholesome and hopeful births, and according to the qualitative and quantitative advance due to its influence made by each generation of citizens born under its influence towards a higher and ampler standard of life. He preaches a thoughtful sermon on the serious aspect of our private lives, the general trend of all our social and co-operative undertakings, which should be directed towards the improvement of a succeeding generation, which, in turn, shall prepare still more capably for still better generations to follow. Mr. Wells is brilliant as a novelist, but as an essayist he has climbed to still higher ground. We shall watch the unfolding of his New Republicanism with sympathetic interest.

The Case of Dr. W. T. Law.

THE fund which has been raised, on the initiative of Dr. Paramore, towards the law expenses incurred by Dr. W. T. Law in the recent action which he successfully defended, was handed over to Dr. Law at a meeting held for that purpose under the presidency of Sir William S. Church. The chairman expressed the pleasure he felt at being enabled to offer Dr. Law a mark of the sympathy of the profession in the unpleasant circumstances in which he found himself through no fault of his own, and he insisted on the duty of practitioners to ensure against contingencies of the kind by joining a medical defence society. Dr. Paramore alluded to the brilliant pecuniary achievement represented by the sum of £700, which he claimed was also a grand moral victory. Dr. Law, in acknowledging the presentation, thanked the members of the profession and others who had so generously given him their moral and pecuniary assistance under very trying circumstances, and especially to Dr. Paramore, who had been indefatigable in his efforts. The meeting concluded with a vote of thanks to the proprietors of the Holborn Restaurant for the generous loan of the room for the second time without payment, and this was carried by acclamation.

The Statistics of Longevity.

THE average age at death under existing conditions is forty-four years and nine months, taking males and females together. On analysing the returns, however, we find that women live some three years longer than men, a fact which is easily explained when one reflects upon the greater mortality among male infants and on the greater exposure of men to atmospheric and traumatic vicissitudes, to say nothing of the greater mental wear and tear to which they are subjected. The most satisfactory feature of these statistics, we are told, is the evidence which they afford of the gradually-increasing longevity of the human race. The gain in the average duration of life at the end of last century, as compared with the beginning, amounts apparently to no less than thirteen years, and the process of "prolongevity" is still going on—that, at least, is the first conclusion arrived at from the study of vital statistics. But another explanation is forthcoming of the rising average of the age of death, viz., a decreasing natality. The principal factor in reducing the average duration of life is, of course, the relatively considerable mortality among the young; consequently the smaller the number of children comprised in a given population the higher will be the average age at death. Now, a decreasing natality is a progressively marked feature of all civilised communities, and as this becomes more and more marked in years to come there will, of course, be a corresponding reduction in infantile mortality and a generally higher age at death of the population as a whole. Pushing the argument to its logical conclusion, when there are no more children the mortality will progressively diminish until, when the then generation has passed away, there will be no mortality at all. Statistics evidently require to be handled with discrimination, for they do not always, on close scrutiny, bear out the deductions one is tempted to make.

The Forthcoming Election to the General Medical Council.

It seems that when, as will shortly happen, the term of office of Sir Victor Horsley as member of the General Medical Council comes to an end, there will be a contested election, Mr. Joseph Smith, of Chiswick, having announced his intention of presenting himself as a candidate. Eligible as Mr. Smith would be under any other circumstances, we cannot but think that his appearance on this occasion is ill-timed and even injudicious in view of the immense services which the retiring member has rendered to the profession and also to the Council itself. Sir Victor Horsley has attained a position and an influence on the Council as a direct representative which no one else could reasonably expect to achieve for years to come. It needs an incisive eloquence such as his to fight the battle of the general practitioner against the opposition of purely corporate interests, and his efforts have met with such general approbation and appreciation that we have no doubt as to the issue of the contest, if contest there should be. Sir Victor Horsley has shown that he can rise superior to mere vested interests, and the reforms which he has initiated are still in large measure incomplete. It may be that on reconsideration Mr. Smith will recognise that there are places on the Council which, when they become vacant, he may with more justice aspire to fill than the one to be thrown open on this occasion.

The Teaching of Hygiene in Schools.

If we wish to educate the people in the principles of hygiene no better opportunity of doing so can be found than that afforded by the instruction of school children. The importance of cleanliness of the person, of food and drink, and of the air which we breathe, can be demonstrated in ways which cannot fail to excite the interest and impress the memory of the young. The benefits to be derived from an ample provision of fresh air and the means of obtaining it are peculiarly suitable subjects for object-lessons in practical hygiene. An excellent aid to instruction in this subject is provided by the large diagram which Messrs. Boyle have published illustrating the laws which govern the movement of air and the means by which a supply of fresh air can be secured by employing the powerful natural forces which are ever ready to our hands. This is "the gospel of fresh air" to which the public have been rendered alive in association with the crusade against tuberculosis. This diagram deserves a place on the walls of every school, not only elementary, but even in the higher grades, since the principles involved are such as should be kept prominently before the young at every stage of their career.

Reciprocity of American Medical Diplomas.

The movement in favour of reciprocity of recognition among State medical diplomas in the United States is gaining ground, Illinois taking the lead. It is obviously absurd, in a country like the great republic that university degrees and college diplomas should only be accorded credit within the limits of the State which gives them birth. On the other hand, some States have been, and, for the matter of that, still are, deplorably lax in their maintenance of a standard of professional acquirements, and one can understand that their diplomates should be regarded elsewhere as "undesirables." One advantage of reciprocity will be that the low-standard licensing bodies will have to raise their requirements if their diplomates are to be recognised as fit to practise medicine in other States. Ultimately, no doubt, by a process of evolution, the various universities and medical colleges will be asked to assist in the formation of a general board of medical education, the function of such board being to establish and enforce a minimum standard of excellence as a condition of recognition. The process of evolution so far has been a slow one, but the citizens of the United States are eminently practical men, likely to carry through a reform of this kind in vastly less time than would be required in the hide-bound countries of the Eastern hemisphere.

Pellagrous Affections of the Skin.

Mr. U. Ray, Assistant Surgeon, Uluheria, India, reports that this rather mysterious cutaneous affection was first noticed by him in Saran, in 1900, when he met, in the outdoor dispensary room, some patients who were "troubled with a burning of the skin in the hands and feet and the appearance of a red rash on the skin." He was told that the red spots had been at first painful. They presented a "tense feel" to the touch; and, as this subsided, the skin remained rough and dry. There was a frequent accompaniment of some symptoms of digestive derangement—such as diarrhœa. The tongue was usually red, and "dryish." There was no symptom present which could be referred to central nervous derangement, unless the local cutaneous hyperæsthesia ould be suspected as such. In the early stages of the affection, the cutaneous lesions were disposed to come and go at intervals; but, as time passed, these remained and "became fixed." No granulomatous or nodular growths, suggestive of contamination by leprosy, were detected in any of these cases.

"Paratyphoid" Fever.

There are few groups of organisms more puzzling to the bacteriologist who attempts to distinguish species by rigid lines of demarcation, than the *Bacillus coli* group. By far the most important of these allied species is, of course, the typhoid bacillus, and the tests for its identification from very similar organisms are as numerous as they are uncertain. Of these, the most scientific is the Widal reaction to the genuine typhoid blood, and, taking this as the *sine qua non* of the typhoid bacillus, it has recently been pointed out that there are certain other fevers closely resembling typhoid in their clinical appearances, but caused by a different organism. Several observers have described in particular a disease called variously "paratyphoid" and "paracolon." The temperature chart is typically that of a mild case of typhoid, but crisis is comparatively more common, and death is rare. Pathologically, in the cases examined post mortem, there were no local lesions in the intestine, nor was the spleen enlarged. A rose-colour rash, as in typhoid, is often seen. The Widal reaction is always absent, and a definite bacillus, resembling, but differing from, typhoid, has been isolated from the blood. The disease is somewhat rare, but is probably nearly always confounded with typhoid. The persistent absence of the Widal reaction in supposed cases of the latter should lead physicians to think of this allied disorder.

Anti-Typhoid Inoculation.

The article by Professor Wright, of Netley, published in the current number of the *Lancet*, contains a statistical synopsis of five years' experience of anti-typhoid inoculations in South Africa, India, Egypt, and in the United Kingdom. Speaking generally, the figures appear to show that inoculation confers a distinct measure of protection, both in respect of the lessened incidence of typhoid fever among the inoculated and the lessened case mortality among the inoculated who subsequently contracted the disease. The paper constitutes a valuable addition to our knowledge of this protective measure, but the author is the first to point out that much remains to be done before anti-typhoid inoculation can be expected to afford uniform results.

Intra-Spinal Cocainisation.

When the use of cocaine for extensive anæsthetisation by intra-spinal injection was first introduced it was thought that it would in a very short time drive out of the field the use of general anæsthetics for operation in the lower limbs. As time has passed, however, several limitations have been laid down to its employment, and its risks seem in great measure to counterbalance whatever advantages it may possess over general anæsthetisation. In addition to its positive risks, it has also the disadvantage of not always producing the desired result. For instance, in a case recently reported (*Charlotte Medical Journal*, July, 1902) by Dr. Tucker, of Raleigh, although intra-spinal injection of cocaine was practised on three occasions, in order to amputate the left leg, no anæsthesia was effected on that side, whilst complete anæsthesia of the right limb was obtained. This result held whether the injection was given on the right or left side of the canal.

The Ontario Medical Council.

The General Medical Council is a body which usually comes in for considerably more blame than praise, and those who think that its work might be much better done than at present watch with interest the proceedings of similar bodies in other countries. In such a spirit, we turned to peruse the report of the last session of the Ontario Medical Council, and we certainly found that things are done otherwise in Canada than at home. The most noticeable points about the proceedings are the vigour and freedom of debate, which far surpass anything we are accustomed to in these countries, outside the privilege of Westminster. One member casually refers to a certain statement of another as an "infernal lie," while the same gentleman is described by a third as "a wasp in the tent at a garden-party, and a festive *skeeter*." The latter term is quite beyond our knowledge. Perhaps we should be glad that our Medical Council is not yet a garden-party of this kind, with or without wasps.

Whooping-Cough in Public Conveyances.

A correspondent, whose letter we publish elsewhere, calls attention to a singular lapsus in our sanitary administration. It is a matter of daily experience that careless or ignorant parents convey children obviously suffering from whooping-cough in public conveyances. It is unnecessary to insist upon the extreme infectiousness of this troublesome and, in the aggregate, fatal malady, and it is strange that no steps are taken either to prohibit the practice or even to direct the attention of parents to the impropriety thereof. There is a law against the conveyance of patients suffering from infectious complaints in public conveyances, but in practice this is only held to apply to disease scheduled under the Compulsory Notification of Diseases Act as infectious. Now that the lapsus has been pointed out, it is to be hoped that the authorities will take steps to prohibit, or at any rate to disadvise, the practice.

Government and the Anti-Plague Serum.

The decision of the Indian Government to withdraw its subsidy towards the cost of the preparation of Lustig's serum in Bombay has given rise to adverse comment throughout India. The Bombay Medical Mission have lately held an important meeting in reference thereto, to decide whether the profession should take any steps, and if so what, in order that further investigation in the serum-therapy of plague should be continued. In the debate which took place, and occupied three days, the matter was thoroughly thrashed out, and very varying opinions were aired. On the whole, however, while far from being quite established, the case for Lustig's serum as a useful means of treatment is strong, and no harm can possibly come from thorough investigation. A resolution was unanimously adopted to the effect that some arrangement should be made whereby research work in connection with serum-therapy in Bombay might be continued, leaving the matter open as to the exact value to be attached to Lustig's serum. It is to be hoped that the authorities will pay due attention to the mature opinion of the profession of Bombay.

The Night Staff of a Workhouse Infirmary.

The understaffing of workhouse infirmaries is from time to time demonstrated to a wondering public through the agency of the Coroner's Court. Last week an incident of the kind focussed popular attention for the moment on the scandalously inadequate nature of the night-nursing arrangements at the Lambeth Workhouse Infirmary. An inmate was found in a lavatory with his throat cut, and the jury who inquired into the affair returned a verdict of suicide while of unsound mind, and added a rider to the effect that the wards were not properly supervised at night. The facts upon which the rider was based were as follows: The night nurse had to look after two infirm wards and a sick ward, in all a hundred patients, while she had also to look after anyone who might be taken ill in the body of the workhouse, which comprised 700 more inmates. There was also a night sister who went round the house every two or three hours. It is to be presumed that the Government inspectors of the Local Government Board are aware of this disgraceful state of affairs. The scandal of inadequate nursing is growing beyond all bounds in these latter days of humaner Poor-law administration. The Lambeth Guardians seem destined to come into notoriety on the score of their workhouse management.

The Scientific Aspects of the Bacon-Shakespeare Controversy.

It is amusing to see the scientific allusions in Shakespeare's works dragged in for the purpose of bolstering up the hypothesis of the works in question having been written by Bacon. More amusing still is the fact that the "summary of evidence," in which this aspect of the question is argued, is from the pen of a judge—Judge Webb, of Dublin, an ex-Fellow of Trinity College. His Honour is evidently possessed of considerable ingenuity, but his knowledge of early science does not appear to be on a par with his controversial aptitudes. An able criticism on the judge's contribution to the debate appeared in the last number of the *Westminster Review* from the pen of Dr. John Knott, whose scholarship and scientific attainments give him an almost unfair advantage over the subject of his destructive criticisms. Dr. Knott kicks the ground from beneath the Judge's feet by showing conclusively that Bacon was not a man of science at all, and that his scraps of scientific knowledge were derived from sources accessible to every student of that date. Dr. Knott points out *inter alia* that William Harvey, the discoverer of the circulation of the blood, was Bacon's medical adviser, and that his views thereon were contemptuously rejected by "Bacon, the scientist." It is, indeed, odd that Bacon, who so dogmatically laid down the general lines on which scientific research should be conducted, displayed throughout an incredulous and unsympathetic spirit towards results obtained by the method of direct observation of which he made himself the champion. We commend the *Westminster Review* article to our readers, not exclusively those who take an interest in the controversy, but all who can appreciate a scholarly attack on an untenable position.

"Unknown" Patients at Public Hospitals

A recent occurrence at a London hospital has brought before the public the desirability of some system with regard to the identification of patients brought to a hospital in an unconscious condition. In the particular case in question a child was brought to the Great Northern Hospital in a van by two men, who stated that they had run over the child by accident. The hospital authorities did not take the names of the men, and the child remained five days in the wards, when it was decided to send him to the workhouse infirmary as an "unclaimed"; but the mother had meantime learned of the whereabouts of her child, and took him away. The boy died subsequently, and the Coroner very properly pointed out that the names of the men should have been taken, as it was possible that the death might have resulted from criminal negligence. It is to be feared that a similar laxity prevails in many of the medical charitable institutions of the metropolis. Matters of the kind are left to the police on the ground that the duties of a hospital are purely medical and surgical. It seems clear, however, that the safety of the public demands the immediate introduction of a business-like system of registration of all details connected with the admission of unconscious patients. A matter of this kind might well be considered by the King Edward's Hospital Fund.

The Mosquito and Yellow Fever.

The Liverpool School of Tropical Medicine has won its spurs at an unusually early period of its existence. Already their annals have been hallowed by the name of a martyr to science in the person of Dr. Myers, who contracted yellow fever and died in the recent expedition to Para. His colleague, Dr. Durham, was also attacked by the malady in question, but happily recovered, and has since published an account of the scientific results of the investigation. Briefly stated, his conclusions are that the disease is due to a small bacillus, and that infection is generally caused by the bite of a brown night-biting gnat (*Culex fatigans*), which inoculates the victim with bacilli obtained from yellow fever patients whom it has previously bitten, or from the surroundings of such patients. This report registers a great advance in our knowledge of this deadly tropical disease, although the first steps in the unravelling of the mystery were undoubtedly due to local investigators. There is every prospect that with the present grasp of facts pertinent to the origin of yellow fever its extinction will sooner or later be a necessary consequence. As in many other specific infections, the hope of mankind must depend upon prevention rather than upon cure. The mosquito appears to be a most deadly foe of mankind, and there is no particular reason why the scientific warfare should not prevail against the mosquito, seeing that men of science have already routed armies of the infinitely smaller specific bacteria.

Radical Cure of Hydrocele.

FROM a large experience of the value of two or three drop injections of pure phenol into an emptied tunica vaginalis testis, Drs. Coley and Satterwhaite have been so pleased with the results they obtained that they recommend the use of phenol in small doses for the radical cure of hydrocele. Their procedure consists in the use of a double trocar and cannula, the inner trocar tightly fitting and projecting slightly beyond the outer and bearing a thread at its proximal end, so that it can be attached to any ordinary hypodermic syringe. The inner cannula, being attached to the syringe, is first filled with liquid phenol, and two or three drops injected. Such a small quantity of phenol could not affect the whole of the surface of even a moderate-sized sac, but the sac of a hydrocele is never completely emptied by tapping, and the remaining fluid is quite sufficient, with the added phenol, to excite the necessary adhesive inflammation over the lining membrane of the tunic. The use of pure phenol in this disease is not new, but in the past it fell into disrepute from the untoward results that followed from its use in excessive quantities. But to the authors we are indebted for demonstrating its utility and safety in small doses.

PERSONAL.

SURGEON-CAPTAIN T. J. CREAN, V.C., late of the Imperial Light Horse, has been gazetted as captain in the Royal Army Medical Corps.

AMONG the latest contributions to King Edward's Hospital fund for London is the sum of £105, being the annual subscription of his Majesty the King, founder and patron of the fund.

DR. J. T. C. NASH, Medical Officer of Health of Southend-on-Sea, has been awarded a sum of 125 guineas in recognition of his services in connection with small-pox in that town.

DR. JOHN BURNS, of Glasgow, Vice-President and "Father" of the Faculty of Physicians and Surgeons, has just entered upon his eighty-eighth year, and is still engaged in active consulting practice.

MR. ALFRED WILLETT is to be entertained at dinner by his past house surgeons on the 30th inst., on the occasion of his retirement from the post of surgeon to St. Bartholomew's Hospital, when a presentation will be made to him.

MR. JOSEPH SMITH, M.R.C.S., D.P.H.Camb., of Chiswick, late President of the Incorporated Medical Practitioners' Association, and President of the Society of Members of the Royal College of Surgeons of England, has come forward as a candidate for the seat on the General Medical Council which will shortly become vacant on the expiration of Sir Victor Horsley's term of office.

DR. SCHWENINGER, who attended Prince Bismarck until his death, has been appointed Professor of the History of Medicine at the University of Berlin. According to the New York *Medical Record* Dr. Schweninger was originally given the post of Extraordinary Professor by Bismarck as a mark of gratitude for his success in reducing the Prince's corpulence, and his transfer from the Skin Department to that of Medical History, in which he is not known even to have taken any interest, is sharply criticised.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

As a result of a fall of rain in Belfast on Tuesday night and Wednesday morning, the 2nd and 3rd September, the city was flooded in an extraordinary manner on Wednesday, miles of the principal streets being under water and business practically at a standstill. The floods of water having subsided, a flood of correspondence has followed, and so strong does feeling run that the Lord Mayor has been requisitioned by a number of members of the City Council to hold a special meeting of Council to consider what steps can be taken to avert similar disasters in future. The ' man in the street " attributes these floods—this is the second within a year—to the failure of the main drainage system, while the City authorities piously say they are due to "the act of God," and that no drainage system can be expected to cope with a rainfall of about 2¼ inches in twenty-four hours. Meantime, the daily papers have printed alarming statements of some local medical men regarding the probability of an epidemic of typhoid being caused by the sewage deposited in and under the floors of the houses in the flooded districts.

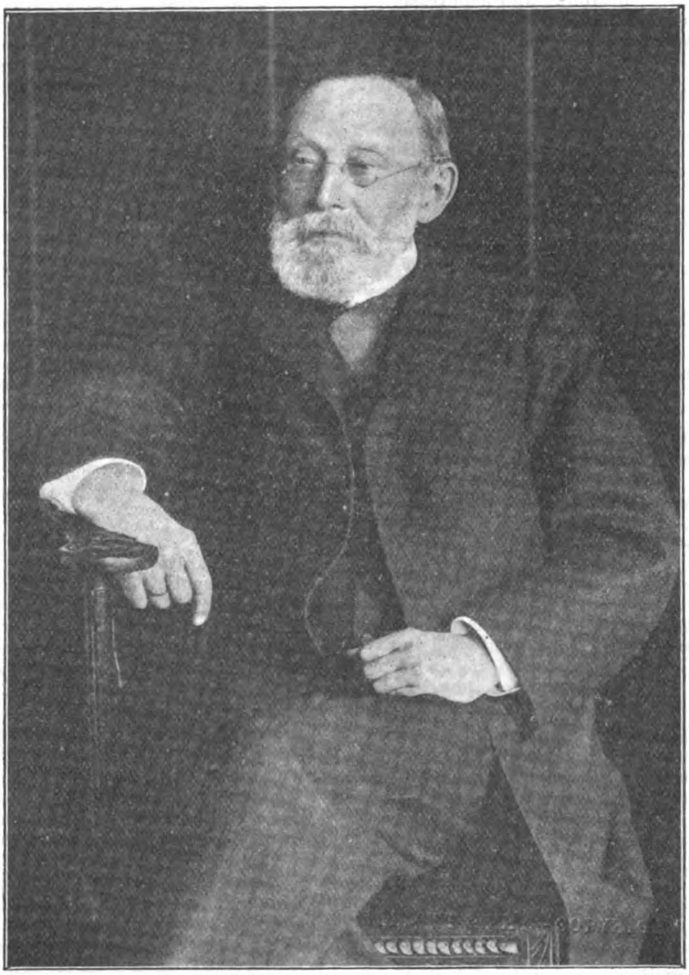
The Belfast Workhouse Supply Scandal, as it is now called, is still before the public. Dr. Smyth's Local Government Board Report was discussed at a meeting of the Guardians on Friday, 5th, but their discretion being greater than their courage, they held the meeting in private. It is stated in the daily Press that Messrs. John Clarke and Co., the contractors to the Board for medicines, &c., repudiate any liability in connection with the matter, but are prepared to indemnify the guardians against any surcharge which may be made as a result of the inquiry. As the *Northern Whig* remarks,] "This is an act so significant that there is no need to comment upon it."

Obituary.

PROFESSOR RUDOLF VIRCHOW.

The unfavourable news of the last few days concerning the critical condition of Professor Virchow were confirmed by his death early on the morning of Friday last. He never really recovered from the injury he received in January last when he sustained a fracture of the neck of the femur, an accident which in persons of advanced years so frequently determines a fatal result. In spite of the reassuring bulletins which were issued up to about a month ago, those in close contact with the illustrious professor were painfully cognisant of his critical plight. While at Harzburg, whither he had been removed in the hope of expediting convalescence, serious symptoms of heart failure made their appearance, and the gravest doubts were felt as to the possibility of conveying him back to Berlin. The journey, however, was safely accomplished on the Saturday preceding his death, but the symptoms of collapse became very pronounced, and he passed away at 2 p.m. on the 5th inst., in the 81st year of his age.

Virchow was a many-sided man. His genius illuminated whatever subject he took in hand, but the Virchow we mourn is the pathologist, the man of science, who for many years led the van of contemporaneous thought, the man who first proclaimed that the processes of disease are merely physiological processes under a different aspect; in other words, merely a form of reaction. He it was who forged the key which has opened the door to the scientific study of disease, furnishing an intelligible hypothesis since confirmed by multiple painstaking investigation.



PROFESSOR VIRCHOW.

From Photograph by Messrs. Elliot and Fry. Copyright.

Virchow was born in 1821, in a small town not far from Stettin, in Pomerania. He took a degree in medicine in 1843, and in 1847 became external lecturer in pathology at the University of Berlin. Soon after he, in conjunction with Renhardt, founded the *Archiv fur Pathologische Anatomie und Physiologie*, which he continued to direct throughout his long and busy career. This scientific periodical forms the storehouse of original research and observation for the last half-century. At this early period of his career Virchow was deputed to report on a severe outbreak of typhus fever in Silesia, and his report, couched in vigorous terms, created a great impression, advocating as it did reforms which, at the time, were judged little short of revolutionary. The influence of this painful experience on Virchow himself was very marked, for he forthwith threw himself into the vortex of politics, and with such zest that he startled his colleagues in the University and was constrained to resign his post.

He was, however, already noted as a man possessed of great scientific acumen, and as an indefatigable worker, and he was forthwith offered the chair of pathology at Würzburg, whither he emigrated. He once more gave himself up wholly to science, which he pursued with the ardour and assiduity which were his lifelong characteristics. The outcome of several years' close study was the famous "Cellular Pathology," published in 1856, which very soon captivated the minds of his scientific contemporaries. As is the case with all epoch-marking departures in science, Virchow's theory of cellular pathology was founded on the work of others, but it needed Virchow's broad grasp and masterly command of details to co-ordinate these views into an organic whole. It is not enough to proclaim a truth—to command acceptance it must be shown to be a truth, facts have to be marshalled, criticisms have to be refuted, and the harmony of the conception has to be demonstrated. Virchow showed that the cell is the unit of life in morbid, as well as in healthy, conditions, and that every cell originates directly from a pre-existing cell. It follows that even the most abnormal structures are derived from normal cells which have undergone abnormal development in response to the irritation caused by injurious influences.

This work at once placed Virchow in a commanding position, a fact which was recognised at Berlin, where he was offered the important post of Professor of Pathology. Students thronged his lecture-room, and his fame spread far and wide. A little later Virchow was elected on the Municipal Council of Berlin, where his remarkable powers of organisation and his technical knowledge ensured him a wide sphere of activity. In 1862 he was elected to the Prussian Chamber, and threw himself into parliamentary life with the ardour and elasticity of a young man, though then over forty years of age. He was a clever speaker, and under the empire of strong opinions his language was apt to be violent. He said what he thought, and said it with emphasis. He retired from active political life in 1878, although in 1880 he became a member of the Reichstag. Professor Virchow visited London several times, the last time in 1898, when he delivered the Huxley Lecture at Charing Cross Medical School on "Recent Advances in Physiology." The completion of his eightieth year last autumn called forth a world-wide demonstration of respect, still fresh in the memories of our readers.

In addition to the "Cellular Pathology," Professor Virchow's contributions to science comprise "Morbid Tumours," "Collection of Treatises on Scientific Medicine," "Collection of Treatises on Public Medicine and Epidemiology," "Goethe as a Naturalist," "Four Lectures on Life and Illness," "The Education of Women," "The Function of Science in the New National Life of Germany," "Free Knowledge in the Modern State," "The Necropolis of Koban in the Caucasus," and "Alimentation and Well-being."

The illustrious professor was one of the most modest and retiring of men, "full of his subject and nothing of himself." Unassuming and affable, he was idolised by those who came under the charm of his manner. "Replete with knowledge, profound and penetrating in thought, plain in utterance, the embodiment of accurate information and sound judgment, the true servant of truth."

The Berlin Town Council decided to organise a public funeral, which was to take place yesterday (Tuesday), and funeral orations are announced to be delivered by Professor Waldayer, of Berlin, Dr. Kirschner, Burgomaster of Berlin, and others.

DR. AVELING, LONDON.

WE regret to learn that Dr. Aveling, of Stamford Hill, met with his death at Mullion (Cornwall), a few days since while attempting to render assistance to a drowning lady, death being due, it is surmised, to syncope. Dr. Aveling had cycled from Mullion to Helston and back, and had then gone for a bathe. The deceased gentleman belonged to a distinguished family, and was M.D. of London and a Fellow of the Royal College of Surgeons of England, &c. Though possessed of singular talent and of general knowledge far beyond the ordinary, Dr. Aveling spread his talents over too wide a field, and as a matter of fact lacked the power of concentration, but for which he would unquestionably have left a name in science.

Literary Notes and Gossip.

AMONG new periodical literature we notice *American Gynecology*, a new monthly journal published in New York; and *Zeitschrift fur allgemeine Physiologie*, a new journal devoted to the exposition of physiological subjects.

⁂

A NEW edition of Dr. Sydney Stephenson's "Ophthalmic Nursing" will shortly be issued by The Scientific Press. This useful work may very advantageously be studied by nurses and dressers who are about to enter the ophthalmic service of a hospital.

⁂

THE Rev. J. E. Kempe, a veteran of ninety-three, has just published, as "The Recollections of a Director," many records of the time when, as deputy-chairman of the Clerical, Medical, and General Life Assurance Society, he came in contact with such lights of the profession as Sir William Bownan, Sir Benjamin Brodie, Dr. Farre, Sir James Paget, Sir Geo. Burrows, Sir W. O. Priestley, and Sir Andrew Clark. Many of the recollections will be of peculiar interest to medical men.

⁂

FOR many years the "Nouvelle Iconographie de la Salpêtrière" has afforded valuable reproductions of many old paintings and interesting drawings illustrating features of medical practice or demonstrations of surgical skill. Dr. Paul Richter has recently published an attractive work on this subject, "L'Art et la Médecine." Anyone at all acquainted with the treasures of British art galleries will at once recall many well-known pictures which have gained their inspiration from medical and surgical science, and we venture to think that in the collection of such portrayals of the healing art, a labour of love might be afforded to any of our readers blessed with artistic taste and—much time.

⁂

"THE Case for Vaccination," by E Brown, M.R.C.S., L.R.C.P. (Baillière, Tindall & Cox), is an *exposé* of the history and principal statistics of vaccination, drawn up in a form suited for the education of the public, special attention being drawn to the control obtainable over small-pox in contrast with the comparative inefficacity of prophylactic measures in respect of other common infective diseases. The case is cogently stated and the reasons given which induce medical men to uphold the practice. This little book, of less than fifty pages, ought to find a place in every village library and every free library throughout the kingdom.

⁂

THE first thing that arrests the attention of the reader of the new volume of the *Edinburgh Medical Journal*, now before us, is the beauty of its illustrations. Plates XI. and XII., opposite pages 552 and 556, are works of art, immeasurably superior to any illustrations that we have ever seen in a medical work. Coming to the letterpress, we find a series of original articles, the great majority of which are on practical subjects by men who have already made their name in the medical world. With these we have a series of reports on the recent advances in medical science, dealing with medicine, surgery, obstetrics, gynæcology, therapeutics, &c. We congratulate the editors on this excellent volume.

⁂

WE have received a copy of the "Supplement to the Royal University Calendar" for this year, containing copies of the examination papers for the different faculties of arts and professional subjects. In medicine the papers set range from very easy to immeasurably difficult. Some examiners seem to think that their speciality is to be the life-work of the candidate. It should be borne in mind that the candidate is probably qualifying for a dispensary practice or one of the Services. It is very desirable that we should have specialists who devote their whole time to their particular branch of medical science; but to ask more than an elementary knowledge of some of the specialities from a medical student, considering the many subjects he must know something of, is wrong.

⁂

THE preparatory essay to the twenty-seventh volume of the "Encyclopædia Britannica," on "The Influence of Modern Research on the Scope of World-History," is from the pen of Dr. Henry Smith Williams, former lecturer in the Hartford School of Sociology, U.S.A. The essay occupies twenty pages of quarto, and deals with such discoveries as have led to broad historic generalisations, regarding such subjects as the Antiquity of Man, the Antiquity of Culture, the Chronology of Ancient History, the Status of Bible History, the Origin and Development of the Art of Writing, and the Evolution of the Fine Arts. It is one of the most interesting of the many contributions with which American physicians have recently enriched general literature.
